
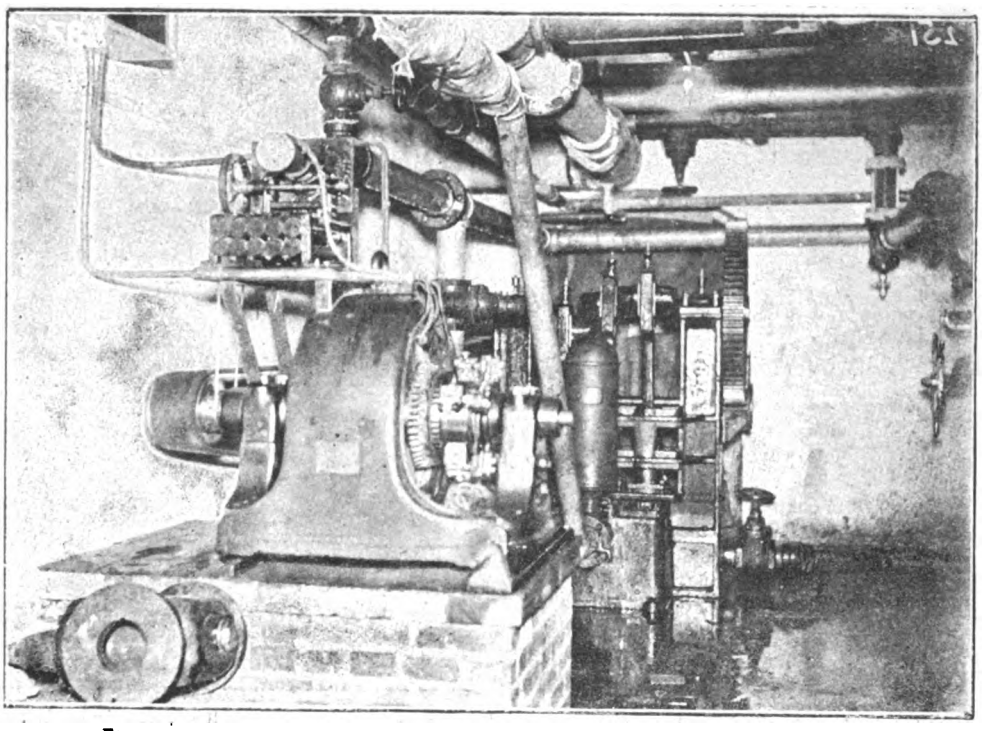

FIG. 5.—10-h.p. Westinghouse Motor operating Triplex Pump, Raleigh Hotel, Washington, D.C.

The hotel water supply is taken from the city mains and passes, after going through a battery of three Loomis-Manning filters, into a large iron tank in the basement. The water is forced from this basement tank to another tank on the roof 160ft. above the basement by a Gould triplex pump, operated by a 10-h.p. Westinghouse electric motor running on the 110-volt circuit. This pump is also connected to the fire lines of the hotel, so that it may be brought into immediate use in case of fire breaking out before the city fire brigade could answer the call. The motor is operated automatically. When the water in the upper tank falls 2·5ft. below its full level, a float actuates the motor switch and closes it; when the water in the tank is up to its full level, the float again comes into action, opening the motor switch and stopping the pump. A 2-h.p. motor is also used to operate another triplex pump, which is for the purpose of lifting the draining from a well in the basement into the city sewers. This motor is also started and stopped by a device similar to the one described above controlling the hotel water supply. A dumb waiter running from the kitchen to the eleventh storey is operated by a 7-h.p. motor. There are several ventilating fans, and also, to alleviate the summer heat, there are a great many small

Digitized by Google

electric fans distributed throughout the hotel. A 1-h.p. motor is used in the kitchen to drive a dish-washing machine. A small rotary converter, taking a current of 2·5 amperes at 110 volts and yielding a current of 10 amperes at 16 volts pressure, is used for the Herzog telesme, with which the hotel is equipped throughout. Each room has a dial with a pointer on which the guest indicates the article or service required, a corresponding indication being given in the kitchen or house quarters of the hotel. These are usually operated by current from cells, but the system here is so extended that it was found to be much more economical to provide a small electrical machine for the purpose.

As yet, since the installation has only been in operation for a few months, no actual figures as to the economy resulting from such an extended use of electricity for hotel work have been obtained, but the convenience and reliability of the whole equipment has been well recognised. There is no doubt, however, that electricity will serve its purpose of actuating labour-saving devices with economy. By so doing, and by increasing the comfort of the guests in so many ways, the popularity, and therefore the financial state, of the hotel which adopts electricity is bound to be considerably improved.

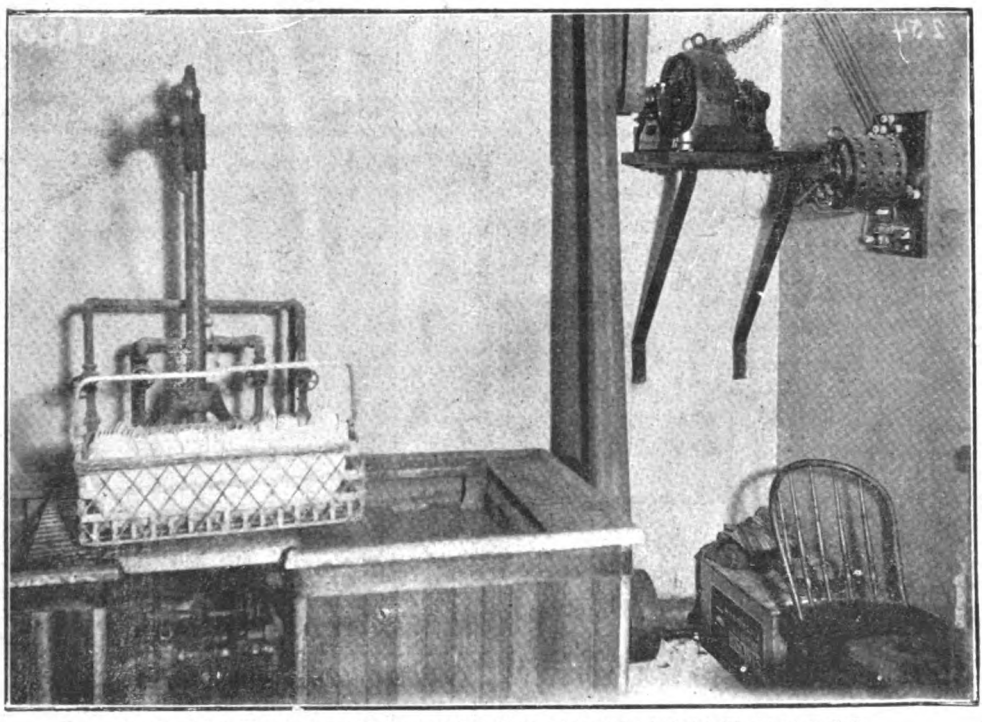

FIG. 7.—1-h.p. Westinghouse Motor operating Dishwasher, Raleigh Hotel, Washington, D.C.

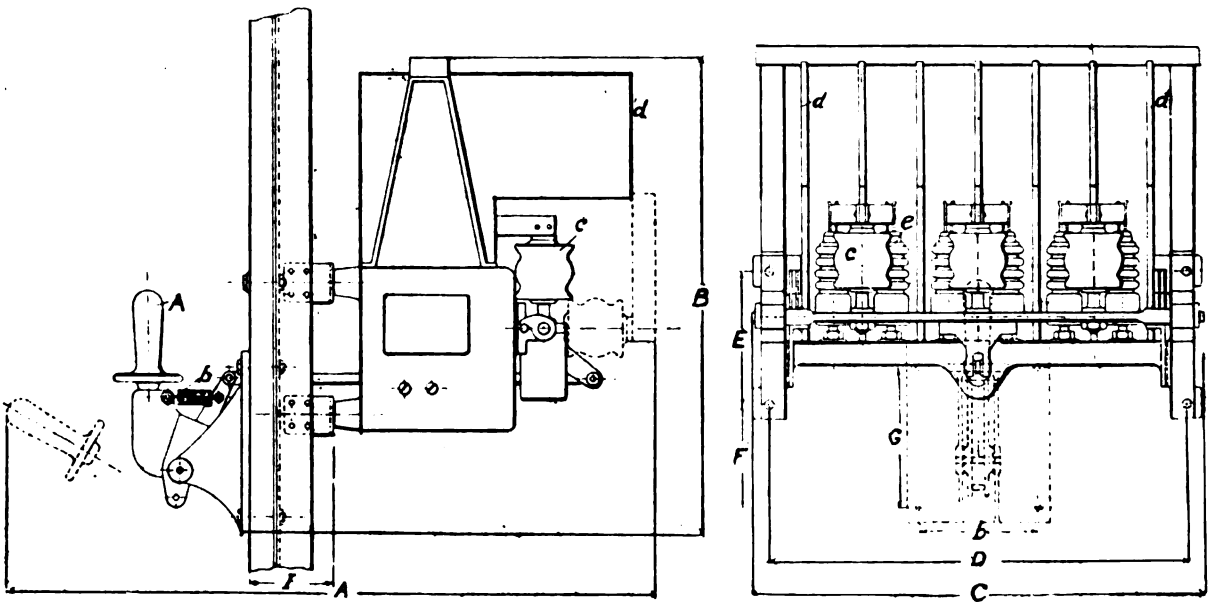
NEW APPARATUS INTRODUCED BY THE HELIOS ELEKTRICITATS AKTIEN-GESELLSCHAFT, KOLN-EHRENFELD.

Herewith we illustrate a new form of high-tension quick-break switch introduced by the Helios Company, of Cologne. Several distinct advantages over types hitherto constructed are claimed for this switch. By means of the quick-break arrangement adopted, an instantaneous breaking of the circuit with a total absence of sparking is effected. All the conducting portions of the switch are arranged behind the switchboard panel, so as to ensure the greatest possible security in working. The action of the switch is extremely simple. As shown in the accompanying diagrams, the switch

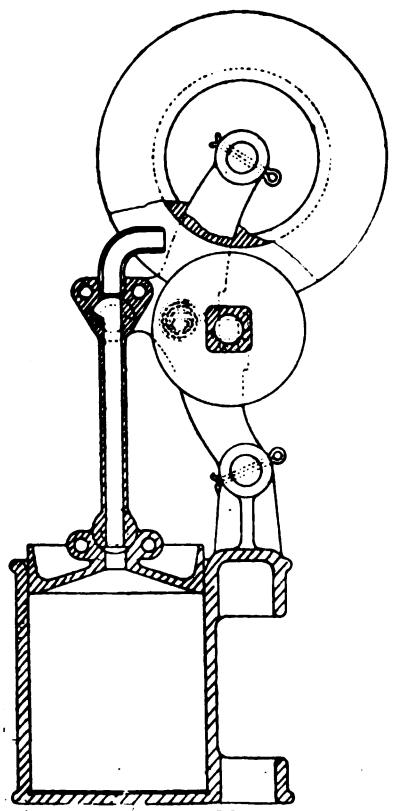
Digitized by Google

lever is attached to a spring arranged at the side of the lever handle, this spring being attached, in turn, through a lever to a connecting rod. In switching out, the elongation of the spring by the handle continues until the catch attached, as shown, to the handle lever releases the lever attached to the connecting rod and spring. At the same moment the circuit is opened with a sudden jerk, the spring having attained its maximum tension. By suitably adjusting the switch, it may be arranged that the circuit shall be broken only when a certain amply sufficient tension has been transferred to the spring. Upon the breaking of the circuit, the knife contacts supported on porcelain insulators describe an upward arc of considerable diameter, by which arrangement, coupled with the double breaking of each pole, the instantaneous elimination of any sparks is effected. The individual breaking points of the switch are insulated from each other by means of partition walls of slate. The conducting portions are mounted upon porcelain insulators, are employed for pressures up to 8,000 volts and current densities up to 500 amperes normal, according as they are to be used for alternating or multiphase currents. By means of a slight structural modification, the switch may also be adapted for pressures up to 15,000 volts. Practical experience with this type of switch gear has yielded, we are informed, most satisfactory results.



High-Tension Quick-Break Switch, Helios Company.

Another piece of apparatus recently introduced by the same firm is a device for lubricating the trolley wire of an electric railway. We referred to this device in a note some weeks since, but are now able to give further details, together with an illustration of the same. In the case of an electric railway equipped for the overhead trolley system the cast-iron frame being attached to the iron framework of the switchboard, and in this way connected direct to earth. Two or three pole switches of the type described



Trolley Wire Lubricator, Helios Company.

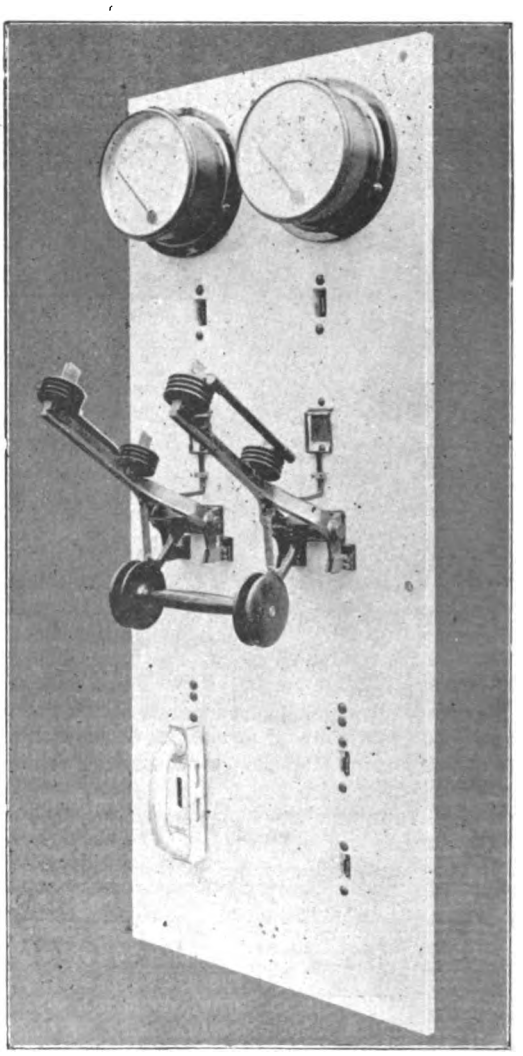


FIG. 1.—View of High-Tension Switch, designed by Mr. Reginald Wilson.

Digitized by Google

of electric traction, a wearing away both of the trolley wire and the collector bow or pulley naturally takes place, this wear being the greater the rougher and drier the surfaces in moving contact. Frequent attempts have, therefore, been made to reduce this wear by lessening the friction between the surfaces in contact, and in order to effect this purpose lubrication has been resorted to. Especially when collector bows have been employed, lubrication has been found essential in order to prevent rapid wear of the moving parts. Of the methods hitherto employed, perhaps the practice of liberally greasing the collector bow so that it may transfer some of the lubricant to the under surface of the trolley wire has found the greatest favour. But this practice is attended with the disadvantage that the lubricant is thereby distributed very unevenly in the neighbourhood of the termini or car depôts, an excess being transferred to portions of the trolley wire, while the more distant stretches are inadequately provided. The excess lubricant transferred to the trolley wire in the neighbourhood of the car-sheds is, moreover, liable to fall upon the roofs of the cars or on to the pavement, thus creating a nuisance. The device introduced by the Helios Company is therefore designed to effect a light and uniform lubrication of the trolley wire. Another feature of the device is that it may be employed with advantage, also, where the current is taken from the trolley wire by means of pulley collectors, since experience has shown the wear of the surfaces in contact even with the pulley to be no negligible quantity. By virtue of its slight weight and simplicity of construction, the device may be attached to the collector arm if desired. The apparatus shown herewith is constructed entirely of aluminium. Its principal dimensions are maximum height: 14in.; breadth, 4in. × 6in. The reservoir is designed to hold about 2¼lb. of lubricant, which is probably sufficient to cover a stretch of 2 to 2½ miles. As shown, the apparatus consists of a roller carried by a movable frame, pivoted to which latter is a piston which works in the lubricant reservoir or cylinder. The frame takes the form of a crooked lever, so that when the roller is pressed against the trolley wire the piston is forced down into the lubricant cylinder so far as the consumption of lubricant through the hollow piston rod allows. In order to distribute the lubricant uniformly in the groove of the transferring roller, and hence to the trolley wire, the lubricant, upon leaving the discharge nozzle is pressed lightly into the groove of the transferring roller by means of a rubber disc. In this manner a light uniform coating of lubricant is transferred to the underside of the trolley wire. The lubricator may be attached in several ways, or applied by hand with the aid of a long carrying rod.

A HIGH-TENSION SWITCH.

The switch illustrated below is one designed by Mr. Reginald P. Wilson for the Blackheath and Greenwich District electric lighting station. The gear for the station being supplied by Messrs. Johnson and Phillips, of Charlton, they also made this switch for the switchboards in the station. The features of the same are the long and quick double break which is obtained, and which is combined with an insulating shutter, which breaks any arc formed when the circuit is broken. This shutter, worked by a lever connected to the switch handle gear, knocks out any arc which, under unusual circumstances, might be formed, in spite of the good break. It will be remembered that a similar device for knocking out the arc has been used successfully for some years by the British Thomson-Houston Company. Another point in Mr. Wilson's switch is that all the contacts are sunk in the board, and cannot be accidentally touched. He also claims that when the switch is in use it can be handled with safety, as all metal parts connected to the high voltage are well protected. Another arrangement in connection with this switch is shown in Fig. 2, where it is provided with an automatic locking device, so that the switch cannot be closed under ordinary conditions until the synchronising plug connecting the machine with the synchronising transformer is in. The object of this interlocking is to prevent a machine which is standing being switched on to the 'bus bars by accident. It also prevents even a machine which is running and is not in synchronism with the 'bus bars being switched on until at least the synchronising connections have been made.

FINANCE.

Now that politics may be presumed to be settled for a time, attention will again be directed to business matters. During the past ten years or so English companies have had an object lesson before them which ought by this time to have pointed a moral. Whether, however, any real decision upon the matter has been formed is a question still undetermined. The evolution of electrical power work and even of electric lighting in America and on the Continent has been determined, not so much from an existing demand, as by financial exploitation in connection with industrial concerns. This is especially the case in connection with tramway work and power distribution. It is easy to understand the reason of this course in the earlier stages of a new industry; the question now to be solved is, will the same course continue? In the earlier stages of electrical engineering the subject was not generally understood, and those who had its interests at heart and understood the matter had to convince a larger public by means of successful work. To carry out such work money was necessary, hence the combination of finance and manufacture. In America companies were formed, each of which controlled a large capital. In Germany the banks came to the assistance of the promoters of the various schemes, and in both countries large works have been carried out under these conditions. Perhaps it is too early to say with certainty whether this kind of forcing an industry has paid or will pay the financiers. According to all accounts, the business returns, whatever the speculative may have been, has hardly warranted, and certainly has not yet rewarded, the risk. The system, although not so extensively used in this country, has been largely used, and is being extended. Financial groups are more or less connected with manufacturing concerns, and even now, in one or two cases, the success or failure of the latter is absolutely dependent upon the success or failure of the former. It is recognised that the work required to be done from the proceedings of these financial groups will be done by the interested manufacturing firms, hence subsidiary questions involved relate to the possibility of the work done being of an inferior quality, and the price at which it is carried out being too high. The immediate success or non-success of a financial group is an entirely different matter to the success or non-success of the undertakings carried out. The former may be immediate, the latter remote. The success of financiers, again, may lead to future troubles, in that they may be tempted to promote enterprises which come under the head of over-promotion, and which, considered soberly, cannot hope to ultimately succeed. But there is another and important consideration. It is found throughout all industrial work that the giving of facilities increases a demand, or even creates a demand. At Niagara and Rheinfelden, facilities were given for obtaining power, the result being the erection and equipment of factories to take advantage of the supply offered. Other similar cases might be mentioned. In these

Digitized by Google

cases the demand has been due to the system pursued in America and on the Continent, and no doubt one result of the erection of power stations in this country will be the same. Probably the first few power stations will have to financed, not by obtaining money from the public, but by syndicates, the members of which will unload when success or partial success is achieved. The possibility of unloading at a profit will depend upon the way in which the facilities offered are taken. We have not attempted to draw any moral at present, only roughly to state a case.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTROMAGNETIC INDUCTION.

SIR,—I think I can promise that this correspondence will not last much longer, for Mr. Johnston's letter this week completely gives his case away. In his first letter (*Electrical Engineer*, Sept. 7) he said: "Suppose that one of the vertical sides was moving in a weaker field than the other, there would in this case still be no change in the number of lines passing through the coil, and yet a current depending upon the difference between the two impressed E.M.F.'s would result." There certainly would be a current if Messrs. Slingo and Brooker's statement is correct, but there certainly would not be a current if Prof. S. P. Thompson is correct in the passage which I quoted last week, which concludes with these words: "Without a variation in the magnetic flux that penetrates the circuit, there will be no induction." Yet Mr. Johnston now actually says that the statement he defends "in no way contradicts either the laws of Faraday or the remarks quoted by Mr. Dunton from [Thompson's] 'Dynamo-Electric Machinery.'" I feel sure that Mr. Johnston is the only one of your readers who has not the ability to perceive the glaring contradiction I have pointed out, and therefore I should be quite content to let the discussion drop. But if Mr. Johnston chooses to take up the new ground that Messrs. Slingo and Brooker are right and Prof. Thompson wrong, I hope he will give a reason for his opinion. So far as the mere weight of authority is concerned, the balance is certainly in my favour. I will not deal further with the minor points, *first raised by Mr. Johnston*, for he complains that this is "drawing the discussion into side issues."—Yours, etc., W. F. DUNTON.

26, Tregothnan-road, Stockwell, S.W., Oct. 6, 1900.

REVIEWS.

Elementary Questions in Electricity and Magnetism. By MAGNUS MACLEAN and E. W. MARCHANT. Longmans, Green, and Co. Price 1s.

One of the most important aids to the real understanding of technical matters is the careful writing of answers to questions bearing upon the subject. It is of great importance that the questions should be properly selected. The engineer, as soon as he enters into practical work, finds that it is necessary to be exact—perhaps we ought to say exact within limits, because in all things human perfection is more or less unattainable. If, however, in his student days, he has been careless about exactitude, he will find himself left behind in the competitive race for success. Any student of electricity who, during his studies, tests his knowledge—if he have no teacher—by means of the questions in this work, will find that it will assist him to better understand his ignorance. There are 24 sections in the book, with questions under each section, there being a total of 311 questions altogether. Besides the questions, a series of 12 very useful tables are given, to which the student will find need of constant reference, and the collection altogether, given in such a way as this, will facilitate such references. The arithmetical value of the answers, when such are required, are given at the end of the book. Altogether, the book should prove of great service to students of electricity.

Electric Wiring Tables. By W. PERREN MAYCOCK, M.I.E.E. Whittaker and Co. 3s. 6d.

This little book is intended for the use of those who undertake electric installations in houses, etc., but the author hopes that it will be also found useful to electrical engineers generally. The information given is contained in about 144 pages, and at first it would seem rather a difficult subject to expand to fill this space. This is done by adding a number of tables connecting the price and quantities of the various materials used in wiring work. Coming now to the contents of the first part of the volume, we find the usual wiring tables, and are pleased to note that the author has taken up the Institution standard in working out his carrying capacities of conductors. The table of contents announces that wiring details and diagrams are to be found on p. 13, and we looked up the reference, hoping to find that some few diagrams of simple connections in wiring work would be given. We find, however, that the page is devoted to the advertisement of another book by the author. We think this hardly fair to the user of the wiring tables, who would naturally expect to get the information which is listed in the table of contents. The information given respecting the incandescent lamps is of the ready reckoner order, as it connects the current required in a great number of voltages with definite numbers of lamps consuming certain watts per candle-power. This will be of service to the wireman who objects to elementary mathematics. The page devoted to the amount of light required and to the arrangement of the lamps is also open to objection, on the grounds of scanty information. Surely, in a handy book for use by wiring contractors, more information should be given on this most essential subject. The page concludes with the statement that it is obviously impossible to formulate any rule to meet all cases, and suggests that for ordinary purposes one watt per square foot of floor area affords a useful basis on which to work. When the watts per candle-power of incandescent lamps are given by the author as varying between 2½ and 4½, the absurdity of this basis of comparison is obvious. It is not the watts which light a room, but the candle-power, and we think the user of these wiring tables has a right to expect a general idea, at any rate, of the candle-power required under various conditions, such as regards the purpose for which the rooms are used, and the scheme of colouring adopted in the rooms. Some tables as to the insulation resistance required by various authorities, and also as to the pressure drop, are given, after which we come to the price-list portion of the book, which is hardly of technical interest. On the whole, we think that much more information of an expert character ought to be introduced into a book of this kind, which is to assist the wireman in carrying out his work, and for which he has to pay 3s. 6d.

The A B C of Electricity. By W. H. MEDDOWCROFT. Sixth edition. John Heywood, Deansgate and Ridgefield, Manchester; 29 and 30, Shoe-lane, London, E.C.

This is the sixth English edition of a little work which was first published in New York about 12 years ago under the endorsement of T. A. Edison. The author, to judge from his treatment of the elementary principles of electricity, is evidently a born teacher, for he presents his subject in plain, simple language, thoroughly inducive of familiarising young people with the general outline of the science as well as with the more important electrical inventions which now enter into daily and commercial life even more than at the time of the first issue of the book. Adults who have left school before the completion of the many electrical appliances now in use, and have not the leisure to study the subject in its scientific literature, will be able to gather from the pages of this book all the general information they require in order to keep themselves up to date.

Injectors: their Theory, Construction, and Working. By W. W. F. PULLEN, Wh.Sch., A.M.I.C.E., M.I.M.E., etc. The Technical Publishing Company, 31, Whitworth-street, Manchester.

The book now before us is the second edition of a volume issued by Mr. Pullen in 1893, and which for years has been of great service to those engineers who wish to ascertain full details as to the theory and working of injectors. The explanations of the actions which go on when live steam or exhaust steam is used to force water into a boiler against the boiler pressure are most clearly given, and the higher theory connected with the same is by no means neglected by the author. We are pleased to see that he commences his volume with an index of the symbols used. We wish that all writers on scientific and engineering subjects would do the same for ease and clearness in reading. It is exceedingly awkward when in the middle of a mathematical description of the theory of any engineering problem to have to turn back page after page in the vain attempt to find what a certain insignificant symbol means, and perhaps eventally be unable to understand the reasoning for the want of a knowledge of the symbols used. This is entirely avoided by an index of symbols such as the author has introduced, and which is also a security against the author himself using any symbol with a double meaning, as not infrequently occurs in other cases. Another good feature of the book before us is the large number of practical examples of injectors, which are illustrated and described in detail. Credit is given to the manufacturers who have supplied the information concerning their injectors, but great credit is due to the author himself for the clear way in which he has edited the material supplied. The chapters devoted to the working of injectors and to the examinations which should be made when injectors fail to act, are interesting reading. The chapter devoted to exhaust-steam injectors shows that these are still being manufactured in quantity, although they are not so largely used as live-steam injectors. The eighteenth chapter deals with the problem of using the injector principle for the moving of large volumes of air. One of the most frequent applications of this is the use of a steam jet to obtain a forced draught for boiler purposes, although injectors and ejectors for other engineering applications in which air is to be moved are described. In contradistinction to the usual practice, the author gives the historical summary on injectors at the end of the book instead of at the beginning, and we think that he is not so far wrong in so doing, because the reader who has looked up the theory and present practice is much better able to appreciate the various steps in the development of the machine as shown by the historical chapters. The book is published at 3s. 6d., and should find its place on every mechanical engineer's bookshelf.

HIGH-SPEED RECIPROCATING ENGINES.*

BY ALLAN COATS, B.SC.

(Continued from page 479.)

Fig. 6 shows a section of Messrs. Alley and MacLellan's engine, who are the largest makers in Scotland of high-speed engines. On the expiry of Willans's patent they adopted the air buffer and redesigned their engine. Nearly all single-acting engines place the bottom bush in the centre of the bearing, and thus prevent the splash getting free access to the most important part. This engine is well drained, and is one of the few in which packing rings are put on the air-buffer piston. The valve is kept single-acting by receiver steam. This renders it liable to knock at light loads, and the application of an air buffer to the eccentric cross-head would be an improvement. There is a large receiver space which, in common with the Willans, would require to be well drained to prevent water accumulating. I think that these spaces ought always to have a small steam-trap, and be independent of the engine attendant. There are two bent and two straight ports in these engines. They are very reliable, and the makers' estimate of under 22lb. per indicated horse-power should be easily obtained.

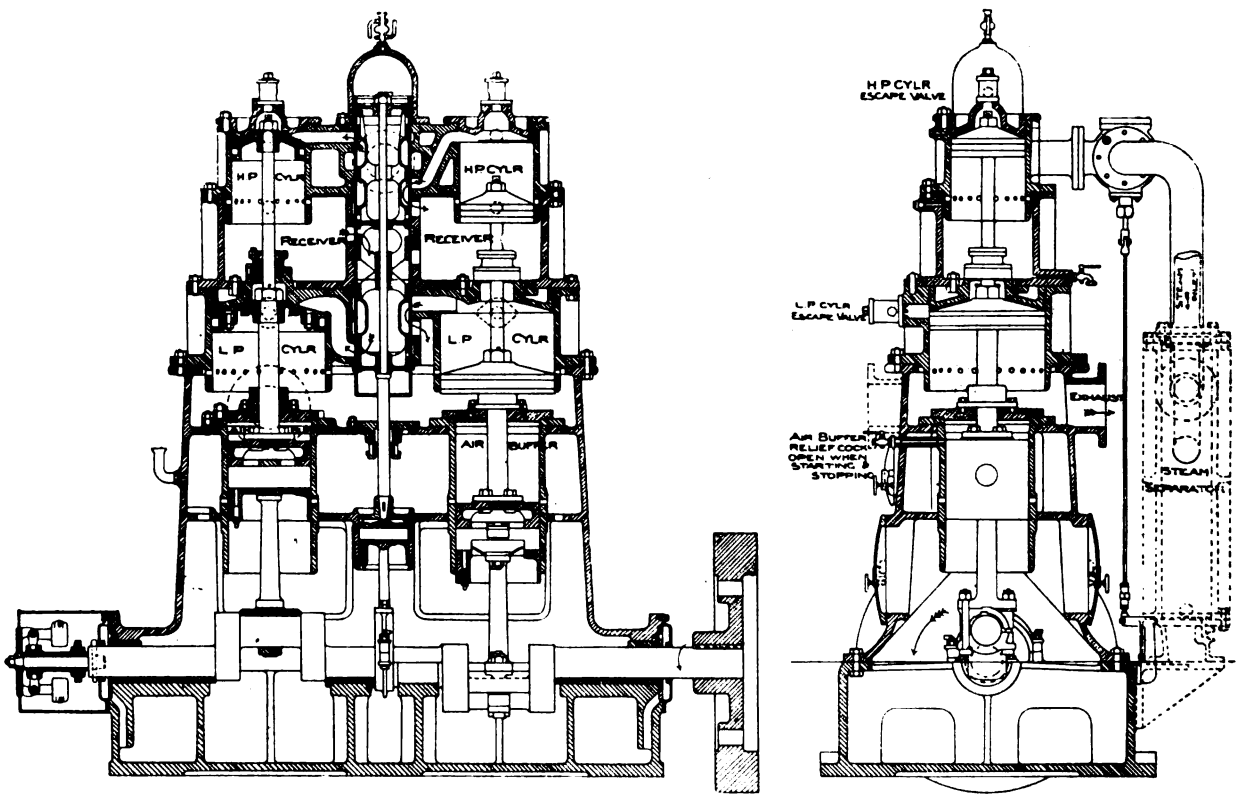

FIG. 6.

Fig. 7 shows an engine made by a local firm, Messrs. Mirlees, Watson, and Yaryan Company, Limited. Steam, after passing the throttle valve on the right and up the dotted pipe, enters the space, A, and when the valve rises enters the space above the high-pressure piston. From thence it exhausts into the receiver space, marked R. This space is almost five times the capacity of the high-pressure cylinder, and extends both before and behind the valve chamber, as shown, and envelopes the high-pressure cylinder for about three-quarters of its circumference. The valve is shown admitting steam from the receiver space to the top of the low-pressure cylinder. From thence on the up stroke it is transferred to the underside of the piston, which corresponds to the transfer chamber of the Willans.

* Paper read before Glasgow Technical College Scientific Society.

Digitized by Google

On the next down stroke the steam passes to exhaust. This engine has, therefore, not only the outside but also the inside of its high-pressure cylinder exposed to receiver steam, which is rather bad practice. The receiver space is very large, and as it is beyond the control of the governor, it tends to produce unsteady governing. The first engine had a much smaller receiver, but it was found that the

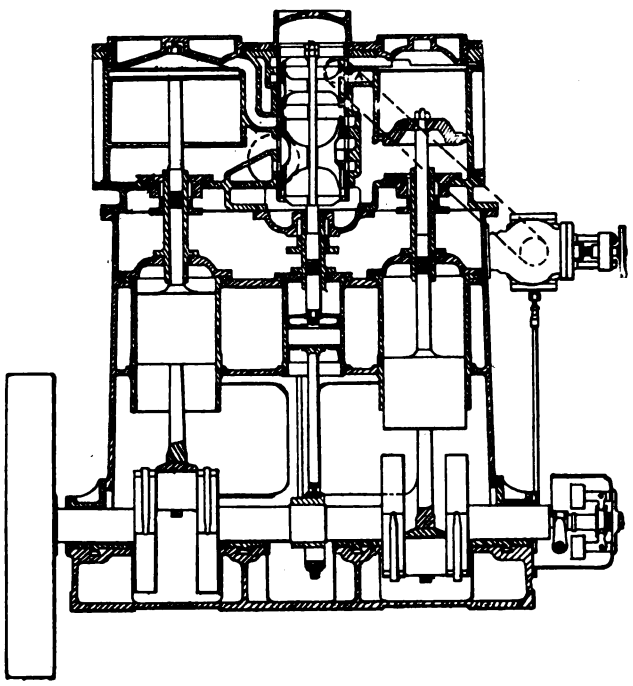

FIG. 7

descending high-pressure piston compressed the receiver steam above the terminal pressure in the high-pressure cylinder, and thus formed a toe to the diagram. Each buffer has very light reciprocating parts attached to it compared to the Willans, etc., so that high speeds can be obtained. This engine illustrated very well the difficulties attending air packing, for packings which held in steam very easily would not, when applied to the air buffer, keep air in at all. The long sleeve shown in the illustration was one of the attempts to overcome this difficulty, but it, too, was discarded. It will be noticed that the air-buffer cylinder, cover, sleeve, and the gland in the steam-cylinders must all be in line with each other and the cylinder. This, as a matter of practice, is rather difficult to attain, and even if right when cold, the steam, by heating up the cylinders, threw the centre lines further apart in the cylinders than in the bed-plate. The line of valves in the first engines had no air buffer, but of course this had to be added, the only curious point being that the wear had taken place at the sides and not at the top and bottom. Messrs. Mirlees's engine, although very well made, was not, I believe, very economical, using rather over than under 24lb. per indicated horse-power, but I have no exact figures on that point.

A more recent engine is one by Reavell and Co., Ipswich (Fig. 8). Steam enters by the left-hand passage shown, and envelopes the entire cylinder, passing up to the small ports (marked A) at the top, passes through these, down the central tube, and enters the high-pressure cylinder by the passages marked C. It is soon cut off, however, and, expanding during the rest of the stroke, exhausts on the up stroke through E and G to the underside of the piston; at half stroke the valve between the upper and lower side of the piston is closed, and steam expands on the underside and is compressed to boiler pressure on the upper side of the piston. This action takes up all the momentum of the parts at normal loads, but at light loads it is forced to rely on two air buffers on the two piston rods. The valve motion is somewhat peculiar; the central tube does not move at all, but the valve moves up and down by means of a bellcrank driven by a link from between the double connecting rod. This saves eccentric room, and gives an extra good valve motion, moving very rapidly when opening and closing, and remaining almost stationary when full open or shut. The makers claim a very high economy, but it is difficult to see why it should be so, the steam cycle being practically midway between a single cylinder cutting off at one-fifth of the stroke and that of an ordinary compound. On account of the central tube, this cycle takes place in a cylinder which has a very large proportion of wall surface to cylinder volume. An explanation of the economy may be found in the fact that the makers do not include the water condensed in the steam-jacket in their steam consumption, but claim that it merely corresponds to the steam separator in other engines. I do not think this is a fair conclusion. The separator in the Willans engine takes the water from the steam before it reaches the engine, and is more useful to prevent an accumulation of water from getting into the cylinders after stoppages, etc., than in actually drying the steam in most cases. Willans found that the amount collected in the separator was so small that it was not worth collecting. On the other hand, by covering his cylinders with a large steam-jacket the results were very different. To quote Captain Sankey, who

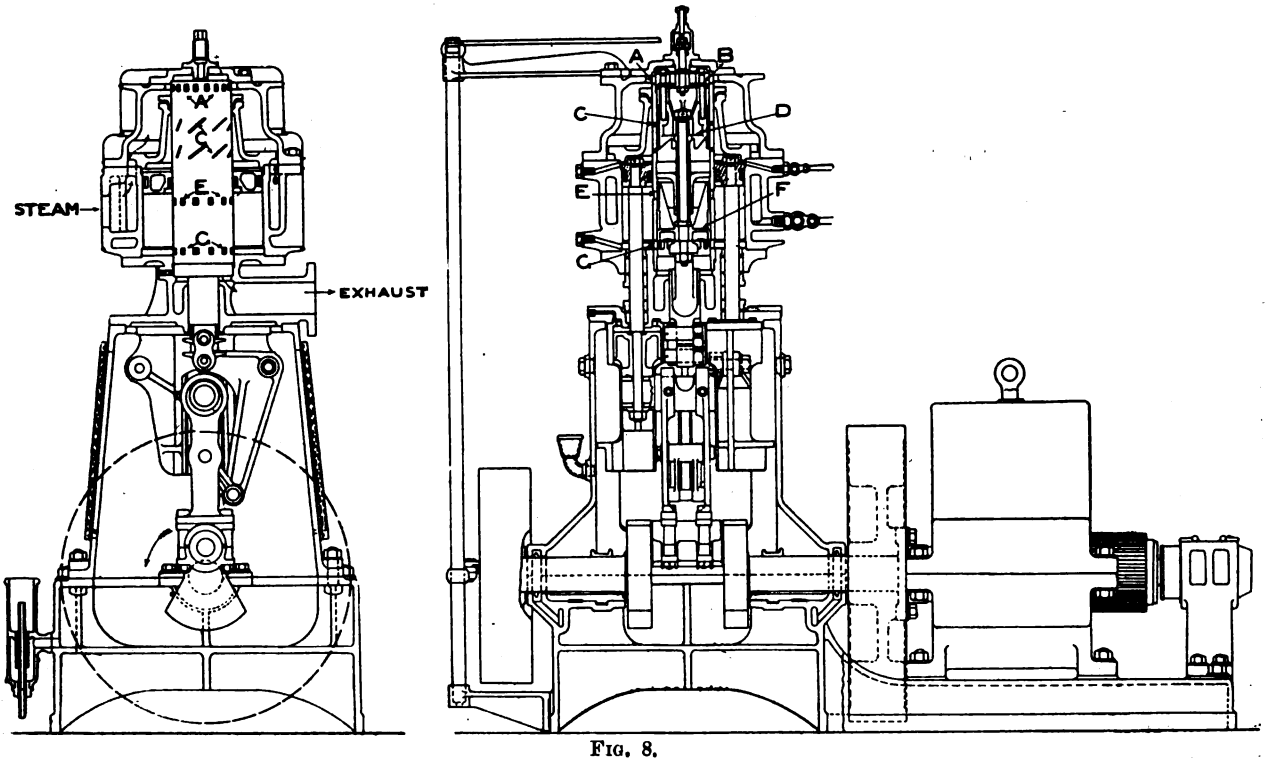

FIG. 8.

Digitized by Google

finished Mr. Willans's paper after he died: "The condensation in this jacket was, of course, enormous, 25 per cent. of steam going through the engine; so the only lesson to be learned was as to the saving in the steam actually passing through the engine."

(To be continued.)

CONNECTING SERVICE CABLES.

It will be remembered that at the recent meeting of the Municipal Electrical Engineers at Huddersfield, the question of the actual cost of making connections between the mains and the consumer's wires was specially referred to in Mr. Wilkinson's paper on "The Distribution of Electricity." The high cost of these service connections is a serious matter in all electrical undertakings, and especially in those cases in which the consumer takes only a few lights. Mr. Wilkinson referred to the fact that service joint-boxes for a triple-concentric cable cost from £2 to £3. 5s. In the discussion on this paper, Mr. Leonard Andrews, the engineer to the Hastings Corporation, stated that he had for some time been using a joint-box which cost only £1, and that one jointer was able to connect as many as eight or ten services in a day. This statement was received with a certain amount of incredulity, but Mr. Andrews has followed the matter up, and now has forwarded us the photographs, which we reproduce herewith, to show the general design of this joint-box, and how it is possible to get the number of joints referred to above made in so short a time. Of

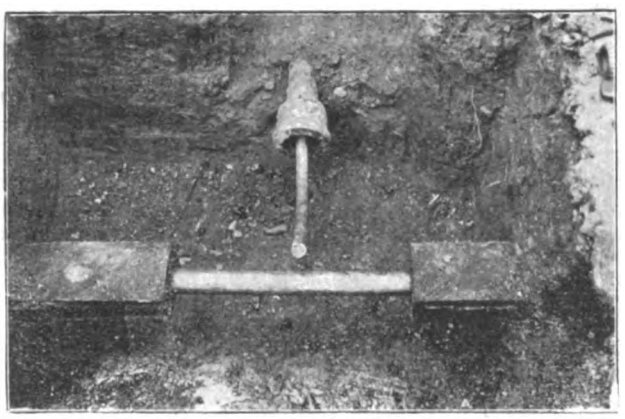

FIG. 1.

these illustrations, Fig. 1 shows the service and main as it was left by the labourers ready for the jointer. Fig. 2 is a photo of the joint exactly 15 minutes after the jointer had commenced work upon it. It will be seen that 3in. or 4in. of the outer insulation has been cut away from both

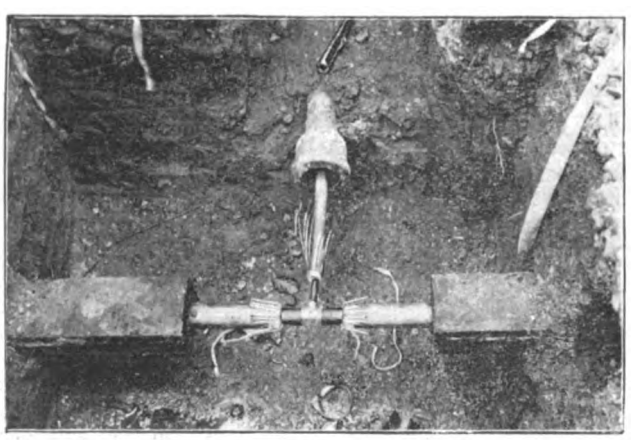

FIG. 2.

cables; the outer conductor of the triple has been cut and splayed back, about 1in. of the insulation between the outer and intermediate conductors has also been cut away, and the inner conductor of the concentric service has been sweated on to the intermediate conductor. Fig. 2A shows the joint in the same stage, except that one of the half clips, used for completing the outer circuit, has been placed in position. The clearance between the inner and outer conductors is here shown. This clearance is filled up when the joint is completed with melted wax or other highly insulating compound. The other half of the conducting clip is shown on the right-hand side of the

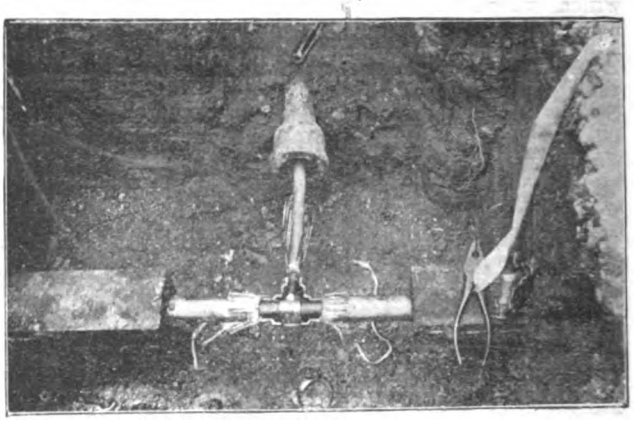

FIG. 2A.

pit in Figs. 2 and 2A. Fig. 3 shows the joint 12 minutes after the photo shown by Fig. 2A was taken. Here it will be seen the outer conductors of each of the cables has been bound and sweated on to the outer conducting clip, and the bottom half of the exterior cast-iron box has been placed in position. The final photo (Fig. 4), taken

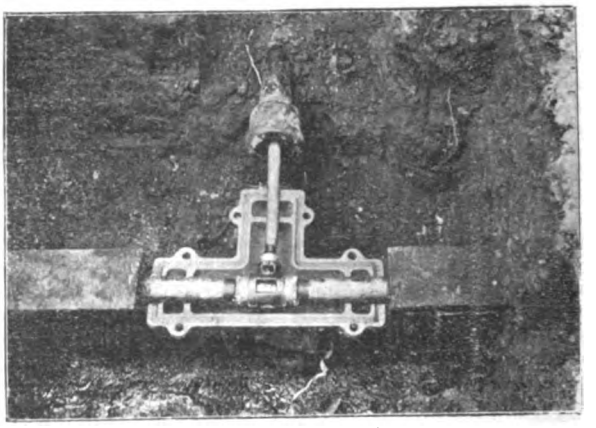

FIG. 3.

6½ minutes later, shows the completed joint with the top half of the cast-iron box bolted into position, and the whole of the space inside the clips and between the clips and the outer box filled with melted wax. The total time taken in making this particular joint

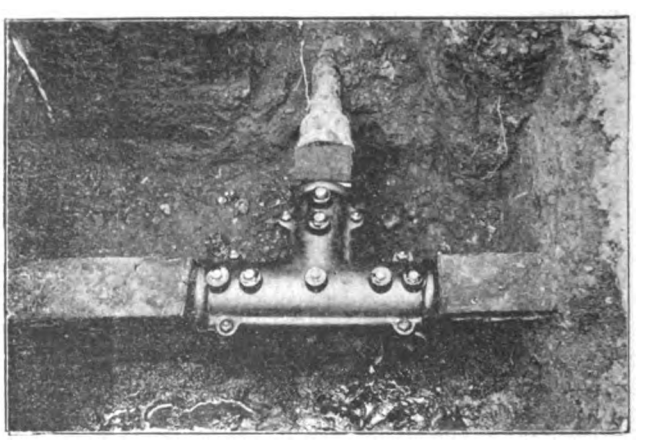

FIG. 4.

from start to finish was just 33½ minutes. Mr. Andrews justly asks if this is not a record for making a service connection. The joint-box, which is illustrated above, is the invention of Mr. J. Glass, the mains foreman of the Hastings Corporation. It has been exclusively used on the Hastings mains during the past 12 months. The insula-

Digitized by Google

tion resistance of a completed joint is usually several hundred megohms, and it will stand a pressure of over 10,000 volts without showing any signs of breaking down. The conductivity of the cable is practically unaffected by a number of joints being taken off in a comparatively short length, as all the joints are soldered, added to which, where services can be taken off the outer and neutral conductors, the neutral conductor is the only one cut. The practice at Hastings is to joint small consumers' services on to the outer and neutral conductors, and large consumers' on to the inner and neutral; by this means the system is balanced by about one inner connection to every four or five outer connections. The process of jointing a service on to the inner conductor is practically the same as that shown by the photographs, the only difference being that an additional pair of half clips are used for connecting up the outer conductor, which in this case has to be cut asunder to enable the inner conductor of the concentric to be jointed on to the inner of the triple. As the completed joint takes up very much less room than an ordinary joint-box, a joint can be made in positions where it would be quite impossible to use an ordinary joint-box. It will be noted that the clearance between the conductors is not in any way dependent upon the skill of the joiner, but is fixed by the branches of the clips resting on the insulation of the cables. These clips are drilled out to fit cables for which they are intended to be used. There are many other useful points about this joint which will be apparent to those using it.

GENERAL ELECTRIC COMPANY, LIMITED.

This company, which for years has been building up its business, is at last about to give the public a chance of sharing in its financial success. The prospectus of the company to be reorganised is now before us, and it will be issued to the public next week. The facts in this prospectus are a good indication of the enormous growth of the concern, which was started in 1880 as Messrs. G. Binswanger and Co. The present directors (Mr. G. Byng, Mr. M. Byng, and Mr. H. Hirst) have been personally responsible for the progress made, while Mr. A. Eckstein has taken in hand the manufacturing side and perfected the productions, both as regards the accuracy of the finish and also in economy. Thus at the present time the valuation of the assets of the company is as follows: freehold land, buildings, plant, and machinery, £140,317; plant and machinery on leasehold property, £21,274; stock-in-trade, £184,843. 15s. 7d.; investments (which produced last year £2,060), £24,640. 18s. 10d.; book debts (guaranteed by the vendor company), cash in hand and at banks, £212,958. 12s. 2d.; goodwill and patents (out of which the vendor company pay all expenses of formation), £92,104. 14s.—£676,139. 0s. 7d.; less debts and liabilities on March 31, 1900, and the profits for the year ended March 31, 1900, reserved to the vendors, £176,139. 0s. 7d.—total, £500,000 (net purchase money). The company will have a capital of £800,000, but at present the following only will be issued. Of these the vendors take £50,000 of the debenture stock, £70,000 of the preference shares, and all the ordinary shares (£250,000, all as fully paid) as purchase money, and about £130,000 in cash.

Now as regards the past profits, Messrs. Edwin Guthrie and Co. report that these were for the year ended March 31, 1898, £51,546. 10s. 7d.; March 31, 1899, £57,034. 3s. 9d.; and for March 31, 1900, £76,804. 12s. 5d.—a total of £185,385. 6s. 9l.; being an average of £61,795. 2s. 3d. per annum over the three years. The foregoing profits are sufficient to pay the interest upon the proposed issue of debenture stock 7½ times over, and after payment of that interest the residue is sufficient to pay the dividend on the proposed issue of £250,000 of preference shares more than four times over.

It is well to note, also, that some £132,841 of the present issue is to be used for the extension of works and for additional working capital. The issue is not underwritten, and the company will remain under the direction of the old directors, who have achieved such a success in the past. Thus, while the present issue is large, it cannot in the light of the above figures be considered at all speculative, and it should attract that class of investors who look for a regular return. We do not doubt but that the business firms of electrical engineers connected with the General Electric Company will take a large share in the new company.

Our Volunteers.—We notice in the list of officers returning home the name of Major Crompton, who left the Cape on Oct. 3 on the ss. "Saxon," homeward bound.

LIGHT RAILWAYS.

The Light Railway Commissioners held an enquiry at the Town Hall, Durham, on the 10th inst.

A largely-attended meeting in support of the Witney, Burford, and Andoversford light railway scheme was held at the Boys' Board School, Burford, on Saturday last. After some discussion the following resolution was carried: "That this meeting of the inhabitants and ratepayers of Burford and district have learned with great satisfaction that the Oxfordshire County Council have resolved to advance £15,000 towards the proposed Witney, Burford, and Andoversford light railway, and trust that the Gloucester County Council will make a like advance at their meeting in October next, and that a copy of this resolution be forwarded to the clerk of the Gloucestershire County Council."

At the Halifax Town Hall on the 8th inst. the Light Railway Commissioners held an enquiry into the light railway which it is proposed to construct from Greetland to Dean Head. There was practically no opposition to the scheme. The scheme provided for two small branch lines to serve quarry traffic, and a branch line connecting the railway with the Calder and Hebble Navigation. The total estimated cost of the undertaking, exclusive of equipment, was £61,117. 14s. The application was that the capital at present should be £55,000 in £1 shares, with the usual limit of £18,000 for borrowing powers. After hearing other evidence, the Chairman said that, subject to the agreements that had been arrived at, they would be pleased to recommend the Board of Trade to grant the order.

The work in connection with the Isle of Axholme light railway is fast proceeding. On Wednesday a party of directors travelled in saloon carriage along the newly-made line from Goole to Crowle. After inspecting the cutting operations through the pit hills, they were conveyed by carriage to Haxey, where they inspected the important work of cutting and banking at Burnham. They returned in the evening, and were highly satisfied with the progress made.

The Light Railway Commissioners held an enquiry at Harrogate on the 9th inst. into the construction of a light railway in the Nidd Valley from Pateley Bridge to Lofthouse.

It is stated that the Commissioners will shortly hold an enquiry into the proposed Jarrow electric tramways.

An offer from Messrs. Leslie and Co. to construct a tramway from Bolton to Cadshaw Bridge, and asking for an interview with the Corporation in regard to the extension of its tramway from the present terminus to Cadshaw Bridge, is being considered by the Parliamentary Committee of the Darwen Corporation.

FORTHCOMING EVENTS.

FRIDAY, OCT 12.

Electro-Harmonic Society.—At St. James's Hall Restaurant, first smoking concert of season.

FRIDAY, OCT. 19.

Institution of Mechanical Engineers.—At 8 p.m., at Institution House, Storey's gate, first monthly meeting. Paper on "Observations on an Improved Glass Revealer for Studying Condensation in Steam Engines and Rendering the Effects Visible," by Mr. Bryan Donkin.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

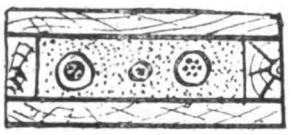
QUESTIONS.

[The following question comes from Brisbane.—ED. *E.E.*]

315. I am in charge of a few miles of underground cable in this city, and I have recently experienced great trouble with them, and would like to ask whether any of your readers have had a similar experience and found the remedy. Our supply is on the three-wire continuous-

Digitized by Google

current system, 220 volts between the outers; the mains are all singles, lead-covered, paper-insulated, laid in tarred sand, protected by hardwood boxing (as shown in sketch).



At every street corner we have 12 cables meeting in a box, and they are all bonded together by a copper wire soldered to the lead sheathing. At each customer's service box hey are also bonded, and in many cases earthed to water-pipe or earth-plate. The lead sheathing has been badly eaten away in certain blocks, but the recent trouble has arisen in those places where the cables are good, on feeders which have no services on them, and which appear quite perfect, except just where the fault has developed and burnt a hole in the sheathing, the lead around the fault being a dark-blue colour and free from any sign of corrosion, whereas all the previous faults were in cables that were so damaged that the paper was visible in spots through the holes eaten by some chemical action. This chemical action seems to be confined to certain blocks in the city, whereas the mysterious faults have occurred in back streets where the cables have hitherto been perfect and still look perfect. It is a curious thing that all these mysterious faults have occurred since the erection of our new switchboard with its quick-break switches, and since we have used the compounding on the balancer machines. The balancers are steam-driven, and were shut down once by a reversal of the current, so they were run as shunt machines until lately. With the new board they run safely with the compound.—W. JOHN YOUNG.

316. Describe the necessaries in construction of a multipolar continuous-current dynamo, in order to obtain sparkless commutation with a fixed position of lead for all loads.

ANSWERS.

Question No. 309.—Explain, with sketches, all the connections of a balancer-booster on the three-wire direct-current system where the booster is used for battery charging.

Answer to No. 309 (*awarded 7s. 6d.*).—The accompanying sketches (Figs. 1 and 2) show the arrangements of balancer-booster sets adopted in generating stations, the one in Fig. 1 being the most usual. The connections explain themselves, and it only remains to describe the functions of the several apparatus. The balancer has been brought into general use in connection with the three-wire system, as it dispenses with a number of small generators, admitting of the substitution of half the number of generators with double the voltage. These are placed across the outers, having no direct connection with the middle wire. Higher efficiency is thus obtained, and it renders the duties of manipulation and regulation easier all round, besides securing economy in steam connections, etc. The duty of the balancer is to supply the "out of balance" current between the two sides of the system, and to keep the pressures constant and equal at the feeding points. It consists essentially of two armatures in series, joined with the outside terminals to the outers and their point of junction to the middle wire. These two armatures are generally run in separate fields with their shafts rigidly coupled together, or the set may be steam-driven, in which case a machine is put each side of the engine and the starting switch dispensed with. (In the diagram of connections, Fig. 1, the set is a motor-driven one.) The excitation is obtained by means of shunt fields, which, it will be noticed, receive their current from the opposite side of the system from that in which its armature is running. This ensures better automatic regulation, for the following reasons: When the demands for current on the two sides are equal, the balancer runs simply as two motors in series. Supposing that the negative side be now more heavily loaded than the positive, the E.M.F. on the negative side drops, while that on the positive increases. As the shunts are reversed, this causes the field, and consequently the E.M.F. of the machine on the positive side, to drop, and it consequently commences running as a motor, driving the

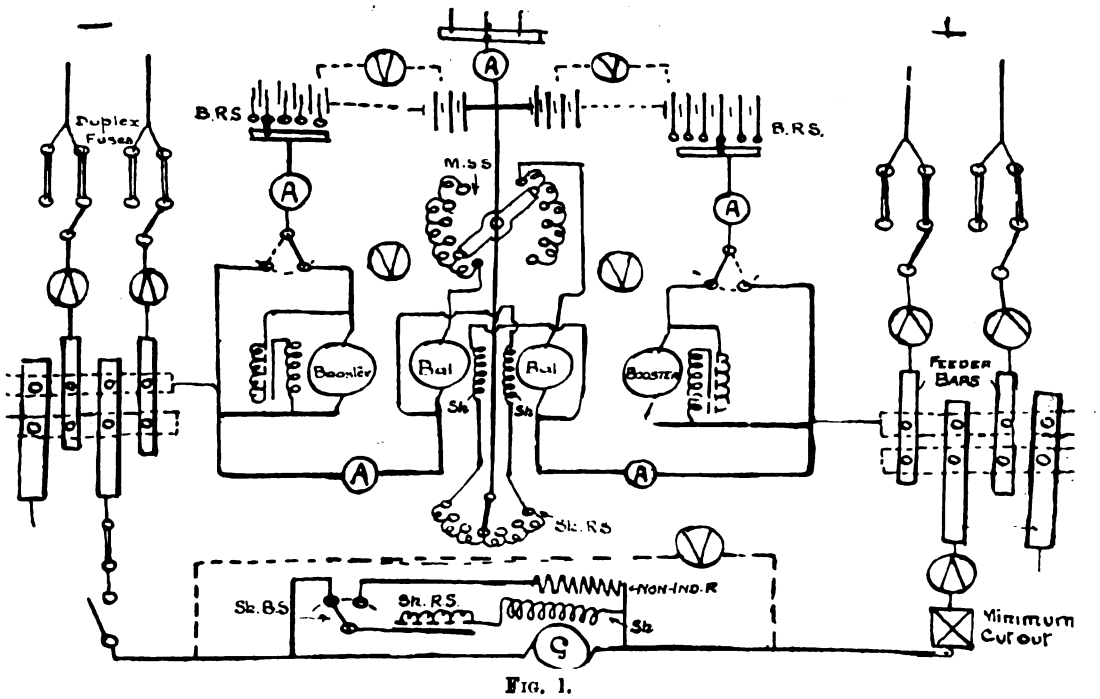


FIG. 1.

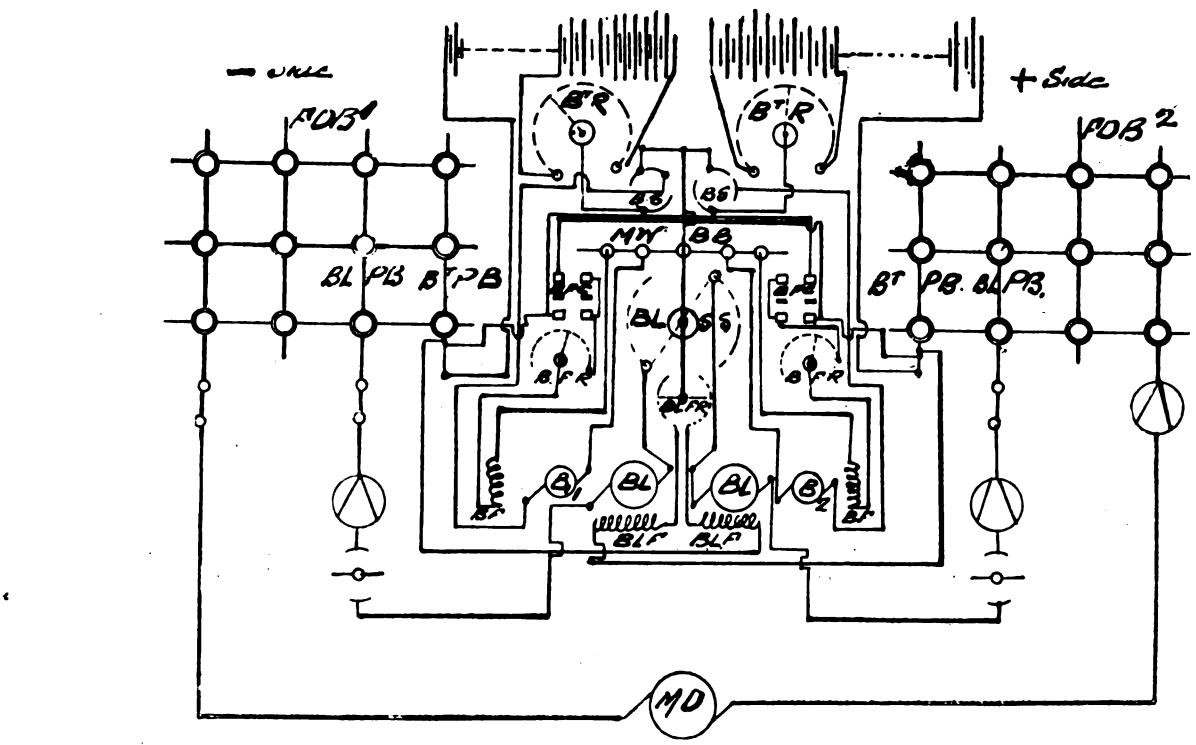
armature on the negative side now as a generator supplying the "out-of-balance" current. The addition of a few series turns wound to have cumulative effect enhances automatic regulation. With the same inequality of load the motor field would be still further weakened, enabling the set to sooner regain equilibrium and the more rigidly to maintain it. Care must, however, be taken to put few enough turns on for the machines still to have a slightly drooping characteristic. Should they be overcompounded, the generator, in the case of an "out of balance," gives out too great a current for the required pressure, and this, in conjunction with the greatly weakened motor field, may pull the set up, burn the fuses out, and also interrupt the supply if there is not another balancer running or a battery serving the same purpose. When the only balancing set on a system is at the generating station, and the feeding points are, say, a mile away, further regulation becomes necessary, as it is at the distributing mains the pressures have to be kept equal. To accomplish this on an "out-of-balance" load, a great difference of voltage between the two sides at the station is often necessary, owing to the greater drop in one of the outers and also the drop on the middle wire, which is generally smaller in cross-section. This drop in the middle wire is rather important, as it assists the lightly-loaded side and operates against the other. This feature is commented upon in

Digitized by Google

p. 139 of "Central-Station Electric Supply," by Gay and Graman, and is rightly urged as one of the objections to a balancer consisting of one core having two windings and running in the same field. It will be obvious that regulation by variation of the field is impossible, and is only obtained by means of the somewhat clumsy arrangement of putting cells in series when required. The further regulation mentioned above is effected by means of one rheostat connected as shown. By moving the lever one way resistance is cut out of, say, the generator field, and consequently puts resistance into the motor field. The motor speeds up, and the generator E.M.F. is further raised.

The relative advantages and disadvantages of steam and motor driven balancers respectively are exclusively considered in the answers to Question No. 225 of this series It is desirable in any case that the characteristics of the two machines should be identical. Where there are motor-driven balancers, the boosters, of which there are generally two, are coupled on their shaft ends, making in all four machines on practically one shaft. The booster armature is connected as shown; one pole to the 'bus bars and one contact of a two-way switch, and the other pole to the other contact. The lever of the switch is connected to the arm of the battery-regulating switch. When it is necessary to charge the battery, the switch is turned so as to include the booster armature in its circuit, and the field is adjusted to generate the E.M.F. over and above that of the mains which is required to charge the whole battery. Where the voltage is 460 across the outers, the booster should be able to supply the requisite current at any voltage between 10 and 100. A point in the design of the booster which is important to keep in mind is that they are required to give out the full charging current with a very weak field (at the beginning of charge). Under these circumstances sparkless collection is difficult to achieve. With the somewhat ingenious arrangement shown in Fig. 2, and used at the Gloucester station, a description of which appeared in the *Electrical Engineer* for July 20, one booster may be done away with. The main battery is charged direct from the mains, and the regulating cells only are charged by the booster. The arms of the charge and discharge switch are so constructed that it is impossible for the charge arm to pass beyond that of discharge, which would reverse some of the regulating cells. The switches in the sketch are in the position ready for charging, and all the connections not shown would be similar to those in Fig 1.—E. J. EVANS.



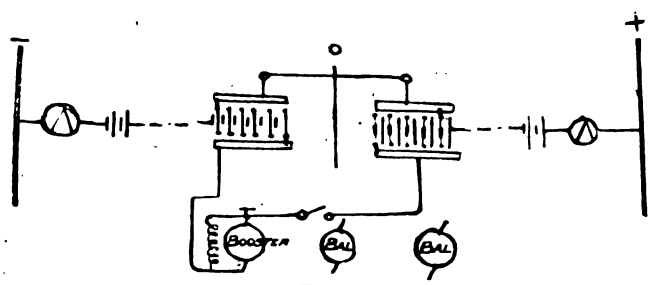


FIG. 2.

Answer to No. 309 (*awarded* 7*s.* 6*d.*).—The term "balancer booster" is generally given to a combination of two balancers and two boosters rigidly coupled together in line, but having their electrical connections coupled to their respective circuits. The balancers usually consist of a pair of generators built as far as possible alike, and having their characteristic curves coinciding so that when running together they may behave alike. Two sets of field magnets are, of course, used, with two armatures and a pair of commutators. In the diagram given, B L is a balancer, coupled one on each side of the three-wire system or the main 'bus bars by means of a plug bar on the outer sides, and direct to the middle wire on the inner sides, a double starting switch, B L S S, being coupled as shown, so that the machines may be brought up to speed gradually. In some instances the outers of the balancers are connected to one 'bus bar only, generally the "common 'bus," but by having a plug bar to each machine, as with the main dynamo, M D, the balancers can then be run on any one of the 'bus bars, and also any particular feeder or feeders. The fields, B L F, are shown cross-connected, the principle of which needs no explanation, as such has been frequently described in these columns. B L F R is a resistance so connected to the middle wire and the balancer field coils, so that a little regulation can be got by moving the switch clockwise or anti-clockwise, thus weakening one and strengthening the other field. The usual field-breaking switch and absorbing coil finds its place in each of the field circuits, but for the sake of clearness is left out of the sketch.

The boosters, as pointed out above, being two in number, should be constructed alike, the amount of "boost" depending, of course, upon the number of extra cells to be charged, but it may be said to vary between 10 to 100 volts for the average station. B_1 in the sketch is the booster for the negative battery, and B_2 for the positive battery. B F denotes the fields in each case, and B F R the shunt regulator, the fields being, of course, shunt wound.

Digitized by Google

In accordance with modern practice, a special change-over field switch, B F C, is shown. This permits the booster field to be reversed, so that instead of the booster standing idle it may be used to help the battery to discharge at a higher pressure when required, and the combination of advantages to be derived will easily be seen from a study of the diagram. B S is the usual booster switch, which is used to put the battery on the main bars and neutral wire, or in circuit with the booster for charging. In some cases a battery emergency switch is used in each battery circuit, but that remains a matter of choice, in the present case the battery fuses being left out for clearness. In the present case the booster is in the diagram arranged to be worked in between the middle wire and cells on each of their respective sides, but in some cases, particularly the earlier systems, the boosters were coupled between the outer bars and the cells. The writer thinks it is, perhaps, an advantage to have the former method, as it is possible then to arrange the balancer booster switch gear all on the middle-wire panel, and so have the controlling of both sets near at hand. Bt P B is the battery plug bar in each case, an addition, perhaps, when compared with other switchboards, but well worth the extra cost when fitted, as it can be brought in to reduce the booster load by plugging on to the 'bus bar working at the higher pressure. F D B^1 and F D B^2 are feeder plug bars, Bt R battery regulator. In order that the diagram may appear as clear as possible, several of the voltmeters and ampere-meters and keys have been omitted, but their positions need no describing to the average reader of this paper.—A. H.

Answer to No. 309 (*awarded* 5*s.*).—The practice at present in vogue in connection with balance-booster sets has, in common with all other electrical practice, been gradually arrived at, and it is only natural that great diversity is found, even with plants being at present laid down, as to the methods employed. The out-of-balance current on the two sides of the three-wire system was first compensated for by the use of steam-driven generating sets, wound for a voltage equal to half that existing between the outers; but as it is generally admitted that this resulted in a loss of economy, particularly on light loads (owing to the necessity of running more than one machine), the practice has gradually given place to that of connecting two dynamos (or motors, as one pleases to call them), with their armatures rigidly coupled together, in series across the supply mains, the middle point being connected to the middle or neutral wire of the system. The practice, too, which was, and even now is in some cases, adopted of using separate motors or steam-driven boosters for supplementing the line voltage when charging the batteries is on the wane, and one generally finds now, in new stations, the armature or armatures of the booster mechanically coupled to the balancing set, for by this means the reserve of power which generally there exists, on light loads is turned to good account.

Fig. 1 shows a plan of connections for such a combination, and for the sake of clearness only absolutely necessary connections have been put in, and the ammeters in the balancer and booster circuits and the booster voltmeter have been omitted. In the first place, the two balancer armatures, B A_1 and B A_2, run as a double motor between the outers, and, in common with other motors, require a starting resistance which can be cut out of circuit gradually as the motor attains its proper speed—such a starting resistance is shown by B S R. The middle point is connected to the neutral wire of the system, N W, and half the resistance is on either side in series with the armature circuit of B A_1 and B A_2 respectively; these halves are simultaneously reduced by the motion of the resistance arm. B F_1 and B F_2 are the balancer fields, in this case connected together through a resistance, R, across the outers—other methods of connection will be referred to later. An arm connected to N W slides over contacts in connection with this resistance; when in the middle position an equal resistance is inserted between N W and either field, but by moving the arm either way the resistance is decreased on that side and increased on the other simultaneously. The reason for so doing is that if one half of the system is more heavily loaded than the other, that half of the balancer tends to act as a dynamo, and if the resistance arm is moved, cutting out resistance on the dynamo side, the field is strengthened on that side and the voltage raised, and at the same time the motor field is weakened by increased resistance in circuit, and the armature tends to increase its speed to make up for the drop in back E.M.F. caused by this weakening of field. This increase in speed still further helps the dynamo side to cope with its load.

K_1 and K_2 are two booster armatures, which each have one terminal connected respectively to the + and − mains and the other terminals to the throw-over switches, T O S_1 and T O S_2, so that K_1 and K_2 are each in

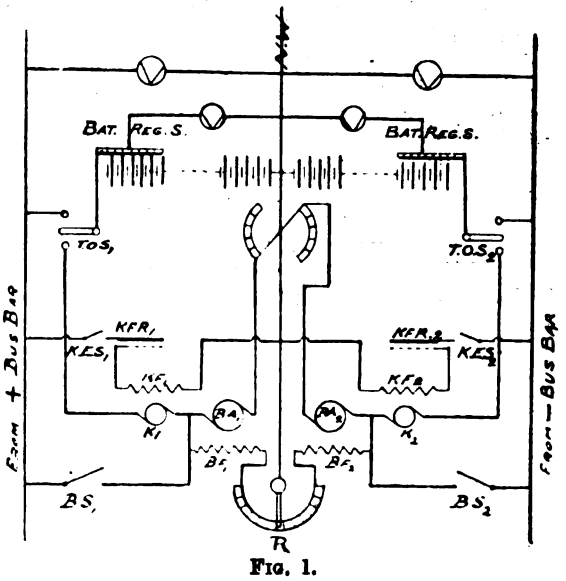

Fig. 1.

series, starting from N W, with one-half of the system, and therefore these contacts of T O S_1 and T O S_2 acquire a difference of potential from the neutral wire equal to that of half of the system + the booster voltage. The battery is connected by its middle point to N W, and its extreme ends are joined through a battery-regulating switch to the top contacts of T O S_1 and T O S_2. When the switch arms are in connection with these top contacts, the battery is in parallel with the mains, but when on the lower contacts, it is connected to the mains through the booster, and the excess voltage thus derived at its terminals causes it to commence charging. K F_1 and K F_2 are the booster fields connected, not across the booster terminals, but between the middle and outer wire in each half, for by so connecting, a much steadier field is obtained than would otherwise be the case. In series with these fields are large

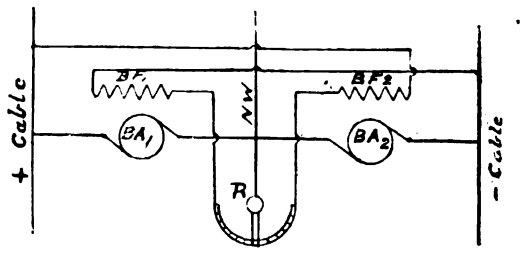

Fig. 2.

shunt resistances, K F R_1 and K F R_2 (owing to the large range of voltage generally required—viz, 40 to 125 volts), and special field switches, K F S_1 and K F S_2, which, when breaking the circuit, short-circuit the field coils through a non-inductive resistance, and thus reduce the instantaneous rise of voltage due to self induction in the coils. Space will not permit to give particulars of these switches, of which many forms exist. Such is about the simplest system of connections for a booster-balancer set; now to come to some variations that exist in practice.

Several methods are in vogue for connecting up the balancer fields: (1) To connect the two fields in series across the outers without any middle-wire connection; this gives a steady field, but does not permit of independent regulation. (2) Each field connected across the armature circuit, with a separate resistance in series with each

Digitized by Google

field. (3) Each field connected across the terminals of the other armature, as shown in Fig. 2. This makes the set to a certain extent self-regulating, as a heavy load on one side strengthens the field on that side and weakens it on the other. It is well to have an adjustable resistance, however, as in figure. Sometimes the booster fields are connected in series across the outers with one resistance in circuit, and there are cases in which only one booster armature is employed. In some stations connections exist so that each booster may be employed to charge either half of the cells. Balancers, too, may be found having the two windings on one armature and a commutator at each end, but difficulties in regulation have been the means of causing this system to drop out of fashion, in spite of its lower first cost.

Enough, however, has, I think, been said to give a general idea of the systems in vogue of connecting up balancer boosters.—W. G. MURRIN.

Question No. 310.—Describe a method of determining the current (with a certain temperature rise, say, 100deg. F.) which can be carried by high-resistance wires, such as platinoid, rheostene, tinned iron wire, etc., when used for resistance coils, and when their specific resistance is not known.

Best Answer to No. 310 (*awarded* 10*s.*).—The specific resistance of any of these materials could, of course, be readily obtained from a measurement of the resistance of a short length of the wire by a Wheatstone's bridge or other method, but, even knowing this, it would not be safe, if accurate results are required, to predict the temperature rise from any general rule, as so much depends on the actual arrangement of the wire in the resistance frame and the amount of ventilation. It is much better to make an experiment. A length of the wire under consideration of any convenient diameter should be wound up into a spiral of about the same form as will be used in the resistance (say, a 1in. diameter spiral with four or five turns to the inch if of No. 12 wire, or a ½in. diameter spiral with seven or eight spirals per inch if of No. 18 gauge or thereabouts). This should be placed in a ventilated frame more or less like the proper resistance frame. A current should then be passed through it, and the final temperature rise noted by means of a thermometer suspended in the centre of the spiral. The test should be repeated with two or three different currents, some giving temperature rises below 100deg. F., and some above it. A curve can then be drawn connecting temperature rise and current, and the exact current for 100deg. F. rise with that wire can then be read off. The result thus obtained can then be used for the determination of the correct current for other wires of the same material but of different diameters, so long as the general arrangements of the resistance frame remain unchanged. For let A be the current which, by experiment, gives the required temperature rise with a wire of diameter D, and a the unknown current, which will give the same rise with a wire of diameter d. Then the watts lost in a given length of the first wire are $\propto \frac{A^2}{D^2}$ (since the resistance of the wire is proportional to $\frac{1}{D^2}$).

The cooling surface of this length of wire is $\propto$ D. $\therefore$ the watts per square inch or the temperature rise $\propto \frac{A^2}{D^2} \div D$, or $\propto \frac{A^2}{D^3}$, or, say $= K \frac{A^2}{D^3}$; where K is a constant depending on the specific resistance of the wire and on the amount of ventilation.

In the same way the temperature rise of the second wire $= K \frac{a^2}{d^3}$. $\therefore$ for the same temperature rise in both $K \frac{A^2}{D^3} = K \frac{a^2}{d^3}$ or $a = A \frac{d^{\frac{3}{2}}}{D^{\frac{3}{2}}}$, or the currents for a given temperature rise are proportional to the $\frac{3}{2}$ powers of the diameters, which is the well-known rule for the heating of bare well-ventilated wires.—Q.

Answer to No. 310 (*awarded* 5*s.*).—The temperature of a body is in a certain sense the measure of the equilibrium of supply of heat to a body and the dissipation of this heat. When the rate of supply is exactly equal to the rate of dissipation, the temperature of the body remains constant. In the case of a resistance coil the supply of heat is produced by the action of a current passing through the wire, and is proportional to the square of the current multiplied by the resistance of the wire. The heat thus produced is dissipated by conduction and convection, and the rate of dissipation varies. In the case of coils enclosed in fireproof cement, the dissipation is wholly effected by conduction through the cement, and the temperatures obtained are high. In the case of spirals of wire hanging in air, the heat is almost entirely carried away by the convection of air currents. The rate of dissipation in the latter case varies according as the coils are closely shielded or are exposed to strong draughts. It can be seen, therefore, that a given current will produce different intensities of heat (temperatures) in the same wire under the different conditions enumerated above.

We should here clear up two essential points. The heat developed in the resistance wire $= k \cdot C^2 R$, where k is a constant. But the resistance of a wire $= \frac{l \rho}{a}$, where l = length of wire, ρ = specific resistance, a = sectional area of wire (all in suitable units).

$$\therefore \text{heat developed} = k \cdot C^2 \frac{l \rho}{a}.$$

Now, the heat dissipated is proportional to $m s (t_1 - t_2)$, where m = mass of wire, s = its specific heat, t_1 = mean temperature of wire (the temperature of a wire varies from centre to circumference), t_2 = temperature of substance immediately surrounding the wire. But m varies as $l \times a$: so that when a constant temperature is obtained in the wire (*i.e*, heat generated = heat dissipated) we have that $C^2 \frac{l \rho}{a} = y \cdot l\, a\, s\, (t_1 - t_2)$, where y is another constant, or

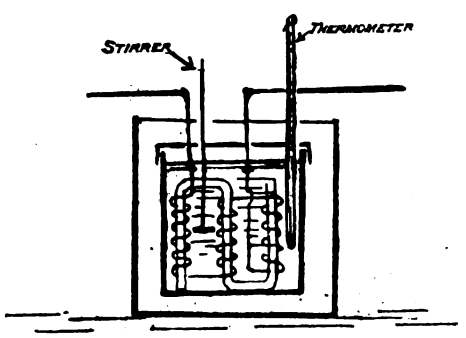
$$C^2 \rho = y\, a^2\, s\, (t_1 - t_2), \text{ or } \frac{c^2}{a^2} = \frac{y\, s\, (t_1 - t_2)}{\rho}$$

$$\therefore t_1 - t_2 = \frac{\rho}{y\, s} \cdot \left(\frac{c}{a}\right)^2$$

$$= x \cdot \left(\frac{c}{a}\right)^2$$

where $x = \frac{\rho}{y\, s}$ = constant. But by hypothesis t_2 is invariable when the coil has been in use a little time, and we are endeavouring to so design our resistance that t_1 is also constant. $\therefore t_1 - t_2$ is constant, and $\therefore \left(\frac{c}{a}\right)^2 = \frac{x}{t_1 - t_2} = K$, where K is a factor determined by experiment. $\therefore \frac{c}{a} = \sqrt{K}$, and $\frac{c}{a}$ is the current density in the wire. Therefore, we learn that (1) the heating effect is independent of the length of the wire (provided that the whole length of the wire is equally exposed); (2) we can determine the above factor by experiment on one specimen, and by using this can readily determine the size of wire necessary to carry any current.

It is a fairly simple matter to determine this constant in the case where the wire is surrounded by a material which conducts heat badly. A piece of the wire (preferably of small diameter) of length, say 24in. (in order to prevent

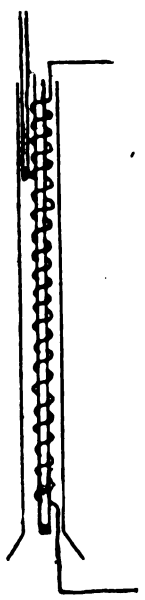


any cooling action at the ends of the wire having a great effect), is coiled round a glass rod, which rod is suitably bent to go inside a small tin or copper pan, somewhat as shown. The wire is soldered at both ends to thick insulated copper leads making circuit with a set of resistance coils

Digitized by Google

(for regulating current), an accurate ammeter, and some cells (preferably a secondary battery) in series. The pan is filled with paraffin oil above the level of the coils, and is covered by a lid having holes in it for (*a*) a stirrer to agitate the oil, (*b*) a thermometer (Fahrenheit in this case), (*c*) the insulated leads. This pan is placed in a large tin packed loosely with cotton wool or silicate cotton. As much as possible of the same substance is placed on the top of the tin. A current is passed and adjusted by the resistance until the thermometer remains steady at the required temperature of 100deg. F., the oil being constantly stirred. A certain time is necessary for the oil to heat up. Once the temperature is attained the current should be kept as steady as possible for, say, a quarter of an hour, and its mean value taken on the galvanometer. The wire should now be unwound from the rod and carefully calipered with a micrometer (or mil) gauge in several places and the mean diameter found. The area is easily determined from this and the current density obtained, from which we get our factor.

The method for determining the factor for coils in air is not so accurate, but as in practice the conditions vary so much, it is sufficiently exact for use. A long glass tube is



wound with the wire under test and connected up as before, and the arrangement placed inside another vertical tube, preferably coned outwards at the bottom. The passage of the current heats the coil and this expands the air in the tube, causing a gentle draught up the outer tube, a condition approximating to practice. If now a thermometer be placed at the top of the tube, it will encounter air which is sensibly at the same heat as the wire, having passed along its whole length. The rest of the experiment is as before.—J. A. S.

Answer to No. 310 (*awarded* 5*s.*).—The simlpest method of determining the carrying capacity of any resistance wire for a definite temperature rise is to pass a gradually-increasing current through the wire until the latter reaches the temperature of boiling water. It is easy to tell when this temperature has been reached by touching the wire with a wetted splinter or needle, and noting whether the water immediately boils off. This method can be applied with considerable accuracy to large sizes of wire, and from these results reliable figures can be calculated for the smaller sizes from the formula $C \propto d^{\frac{3}{2}}$, where C = current, and d = diameter of wire. Suppose, for instance, we want to know how much current a wire ·018in. diameter will carry with a temperature rise of 100deg. F. We take a thick wire, say ·116in. diameter, of the same material, and find that a current of 20 amperes heats it to boiling point from atmospheric temperature 72deg. F., corresponding to a temperature rise of 140deg. F. Then the current to heat our ·116in. wire 100deg. F. will be $20 \times \sqrt{\frac{100}{140}}$ = 17 amperes; therefore the current which will heat our ·018in. diameter wire 100 degrees F. will be $17 \times \left(\frac{\cdot 018}{\cdot 116}\right)^{\frac{3}{2}} = 1$ ampere. In the practical design of resistances several other considerations have to be taken into account, such as the nearness to each other of the spirals, the direction of the ventilating currents of air, etc. DISPAR.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Varna.—The Municipality invite tenders for the lighting of the town by electricity for 40 years by Oct. 15 (concession).

Bermondsey.—The Vestry invite tenders for the erection of steam dynamos, etc. Tenders by Oct. 15. Details in our advertisement columns.

Paris.—The Postal and Telegraph Department, rue de Grenelle, No. 103, invite tenders for a number of telephone apparatus. Tenders by Oct. 16.

Sunderland.—The Corporation invite tenders for 24 car bodies and electrical equipment. Tenders by Oct. 15. Details in our advertisement columns.

Maidstone.—The Corporation invite tenders for a surface condenser and feed pumps. Tenders by Oct. 16. Details in our advertisement columns.

London County Council.—The Council invite tenders for the supply, for one year from Jan. 1 next, of engineers' goods and electrical stores. Tenders by Oct. 29.

Santiago.—Offers are invited for the laying down and working of a telephone system in Santiago de Compostela, in the province of Coruna, Spain. Tenders by Oct. 19.

Palma.—The Municipality of this town, in the province of Baleares, Spain, invite tenders for the installation and maintenance of 60 arc lamps. Tenders by Oct. 30.

Cortegana.—Offers are invited for the installation of electric lighting and the working of same for five years in this town, in the province of Huelva, Spain. Tenders by Oct. 19.

Whitechapel.—The Electrical Committee invite tenders for the supply of a hand-driven overhead travelling crane for their new electricity supply station. Tenders by Oct. 23. Details in our advertisement columns.

Whitehaven.—The Water and Lighting Committee of the Corporation invite tenders for the supply and erection of a switchboard at their electric lighting station. Tenders by Oct. 13. Details in our advertisement columns.

Aberdeen.—The Tramways Committee invite tenders for the manufacture and supply of 25 electrical tramcars, and equipments for six horse cars, about to be converted. Tenders by Oct. 17. Details in our advertisement columns.

Cardiff.—Tenders are invited for slow-speed vertical engines, slow-speed generators, boilers, and economisers. Specifications, etc., may be obtained from Mr. A. Ellis, M.I.E.E., Old Post Office-buildings, Cardiff. Tenders by Oct. 23.

Grantown-on-Spey.—The Commissioners of the burgh invite tenders from electric light companies to supply electric light for public and private consumption within the burgh. Tenders by Nov. 6. Details in our advertisement columns.

Glasgow.—The Corporation invite tenders for (1) cables for connecting up plant; (2) transformer connecting bars. Specification, etc., can be obtained on application to Mr. John Young, general manager, 88, Renfield-street, Glasgow. Tenders by Oct. 13.

Bradford.—The Corporation invite tenders for the construction and erection of a 30-ton electric travelling crane for their new electricity works, Valley-road, to operate on a 500-volt direct-current circuit. Tenders by Oct. 25. Details in our advertisement columns.

Cienfuegos (Cuba).—Tenders are invited for a service of public electric lighting for the above town. Intending contractors can present their estimates and state their conditions until Oct. 26. All enquiries and tenders should be addressed to the Secretary's Office in Cienfuegos, Cuba.

Ayr.—The Corporation invite tenders for supply and delivery of steel tramway rails and fishplates for the work required in connection with the proposed tramways. Specification, etc., may be obtained from Mr. J. Young, C.E., town surveyor, Town Buildings. Tenders by Oct. 12.

London, N.E.—The Acme Wood Flooring Company, Limited invite tenders for the electric lighting (Section 1—wiring) of their mill premises at Victoria Park, N.E. Specification, etc., may be obtained from Messrs. Taylor and Field, 14, Victoria-street, Westminster. Tenders by Oct. 13.

Dartford.—The Urban District Council invite tenders for the erection of an electric light station at Dartford, in accordance with drawings and specifications prepared by their architects. Specifications may be seen at the office of Messrs. Hesketh and Stokes, 110, Cheapside, E.C. Tenders by Oct. 20.

Digitized by Google

Glasgow.—The Corporation invite tenders for the supply of 1,000, 2,000, or 3,000 tons steel straight track rails; 100, 200, or 300 tons steel curved rails; 50, 100, or 150 tons steel fishplates. Specifications, etc., can be obtained from Mr. John Young, general manager, 88, Renfield-street, Glasgow. Tenders by Oct. 23.

Aberdeen.—The Town Council invite tenders for the supply of materials and the construction of works in connection with the laying down of the permanent way of new electric tramways. Specifications, etc., may be obtained on application to Mr. Wm. Dyack, M.I.C.E., engineer, Town House, Aberdeen. Tenders by Oct. 18.

Whitechapel.—The Board of Works invite tenders for erection of a chimney shaft and the construction of economiser chambers, flues, and cableways at the new electrical supply station yard, Osborne-street, Whitechapel, E. Drawings may be seen at the office of Mr. M. W. Jameson, engineer and surveyor to the Board. Tenders by Oct. 16.

London (City).—The Streets Committee of the Corporation invite tenders for the hiring of a mechanically-driven dust-cart for collecting and removing the dust, trade refuse, and street sweepings from the City to the Corporation's depôt at Lett's Wharf, Commercial-road, Lambeth, S.E. Tenders by Nov. 10. Details in our advertisement columns.

Kendal.—The Corporation invite tenders for building engine-house, boiler-house, accumulator-house, chimney shaft, offices, etc., in connection with the electric lighting station to be erected at the gasworks, Kendal. Specification, etc., may be seen at the office of the engineer, Mr. T. N. Ritson, A.M.I.C.E., Gas Offices, Parkside-road, Kendal. Tenders by Oct. 29.

India.—The Secretary of State for India in Council is prepared to receive tenders for the supply of a complete electrical installation for supplying power to a factory from a waterfall about three miles distant from factory. The generator will be required to develop about 500 kw., and the installation is to include complete plant of generators, line, transformers, cables, motors, etc. Conditions, etc., may be obtained from the Director, General Stores, India Office, Whitehall, S.W., and tenders are to be delivered at that office by 2 p.m. on Oct. 16.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul-General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Alteerig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

RESULTS OF TENDERS:

Stockport.—The Council have accepted the tender of Messrs. Dick, Kerr, and Co. for 20 top-seat cars, at £675 each.

Bedford.—The Electric Lighting Committee have accepted the tender of Mr. W. Laughton for building a sub station on the Silver-street Market Hill, at £33. 10s.

Newcastle.—The Council have accepted the contract of the National Construction Company for the supplying and laying of conduits for the additional new tramways at scheduled prices.

Tunbridge Wells.—The tender of Mr. J. Jenkins, Swansea, has been accepted in connection with the erection of chimney shaft, 180ft. in height, at the central electric light station, at £3,835. 2s. 4d.

Rochdale.—The Guardians have accepted the tender of the Edison and Swan United Electric Light Company, Manchester, for the supply of 3,000 yards of tubing and 6,000 yards of wire for an electric light installation at the new workhouse infirmary.

Middleton and Castleton (Lancs.).—The British Electric Traction Company have accepted the tender of G. Freeman and Sons, of Hollinwood, Oldham, at £38,781, for the construction of light railways in Middleton and Castleton, near Manchester (length in all about seven miles).

Bangor.—The Lighting Committee have accepted the tender of Patterson and Harford, at £56. 10s., to supply and fix the necessary fittings required at the electric supply station. The offer of Messrs. Verity to exchange the present testing set for an Evershed ohm-meter at an additional cost of £5. 5s. has been accepted.

War Office.—The War Office have accepted the tender of Pritchetts and Gold, Feltham, Middlesex, for supplying and fixing a battery and stands for each of the three Spithead Forts. There will be 33 cells at the Spitbank Fort and 44 at both Horsesand and Noman's Land Forts, and in all cases the boxes will be of lead-lined teak.

Worksop.—The Electric Lighting Committee have placed the order for the generating plant, balancers, and boosters required for the new electricity works with Witting Bros., Limited, 49, Cannon-street, E.C. The steam dynamos will be three in number, each consisting of a multipolar dynamo of Witting's standard pattern direct coupled to a high speed Scott and Mountain engine.

Grays.—The Urban District Council have accepted the following tenders with regard to the electric light scheme: Messrs. Danks, boilers, £2 325; British Schuckert Company, steam dynamos, £2 147. 10s.; Messrs. Green, economiser, £241. 10s.; General Electric Company, switchboards, £628. 15s.; D.P. Battery Company, battery, £836. 1s.; Messrs. Carrick and Ritchie, crane, £95. 10s.; Messrs. Callender, cables, £3,545; electric light buildings, £4,174; engineering and road work, £1,005. 14s.—total, $15,000.

Worthing.—The Corporation have received the following tenders for supply of electric lighting plant:

BUSINESS NOTES.

TRACTION.

Bury. — Messrs. Lacey, Clirehugh, and Sillar have been appointed consulting engineers for tramway purposes.

Falkirk.—The Town Council have appointed a committee to draft an agreement with the electric tramway company.

Lowestoft.—We understand that the Corporation have engaged Mr. Walter Beer to prepare plans, etc., for the Corporation's tramway scheme.

Folkestone.—The Town Council on Wednesday decided to apply for parliamentary powers to construct electric tramways, at an estimated cost of £93,000.

Plymouth.—The possibility of extending the Lipson tramway round into the Alexandra-road will be considered by the Tramways Committee at their next meeting.

Dundee.—The electric system on the Lochee tramway route is now practically completed, and a trial run was made on Saturday, when everything was found to work smoothly.

Wigan.—We understand that the first line of track of the electric tramways will be opened in the first week of December.

Turton.—The Tramways Committee of the Bolton Corporation have resolved not to make any offer to the Turton District Council with reference to the proposed tramways in their district.

Lincoln.—The City Council have made a grant of 100 guineas to Mr. Vesey Brown, electrical engineer, for his services in connection with the Lincoln Corporation (Tramways) Act, 1900.

Eccles.—The Town Council have resolved to promote a Bill in the ensuing session of Parliament for doubling and altering the existing tramlines in the borough for electric traction purposes, etc.

Erdington.—At the next meeting of the District Council a resolution will be proposed affirming the advantage of constructing at once a system of tramways properly equipped on an up-to-date system.

Darwen.—Five of the new cars have already been delivered. The Council have promised to give the application of Hoddlesdon with reference to tramways being laid to that place their closest attention.

Liverpool.—The tramway extension debate at the City Council on Wednesday was without definite result. The Irish Nationalist members refused to vote, and thus the statutory number of 78 votes could not be obtained.

Redcar.—The Redcar Urban Council, having decided to institute power for electric light, have now been advised to have electric trams in the town, either for the convenience of visitors or for inter-communication between Redcar and Saltburn.

Leeds.—The receipts from the city tramways last month yielded £16 674. 5s. 6d., as compared with £10,263. 19s. 1d. in September last year. The Dewsbury-road section, recently opened, contributed £1,108. 12s. 4d. and the new Beeston-hill section over £500.

Watering of Tramways.—The legality of watering tramway lines will shortly be tested by the National Cyclists' Union, who are under the impression that excessive watering is a nuisance for which tramway authorities have no justification under their Act of Parliament.

Audenshaw.—At a recent special meeting of the Council a formal resolution was passed requiring the Manchester Carriage Company to sell to the Council so much of the tramway undertaking as authorised by the Manchester Suburban Act, and upon terms specified in the Act.

Shipley.—The Bradford Tramways Committee intend to recommend the Corporation to extend their tramways to Dumb Mill, Frizinghall, and to run through Shipley and Windhill to Thackley, and also along the Otley-road, Shipley, in the direction of Charlestown, and Tong Park, Baildon.

Birkdale.—Notice is to be served upon the Southport Tramway Company requiring that company to sell to the Birkdale Urban District Council so much of their undertaking authorised by the Southport Tramways Order, 1872, as is situate in the said urban district, upon the terms specified in the said section.

Aberdeen.—The Tramways Committee have under consideration the question of converting the Constitution street baths into tramway sheds, and a report as to the cost of such a scheme is to be obtained. Mr. Bell and Mr. Moonie have taken steps to immediately procure cow-catchers to be put in front of the fenders on the cars.

Chester.—The Town Council on Wednesday resolved to apply to Parliament for an Act empowering them to take over the Chester tramway undertaking and to adapt it for mechanical traction, and to extend the system beyond the borough boundaries. The price to be paid by the Council to the tramway company is £18,300, plus the rolling-stock at a valuation.

Lee.—At a recent meeting of the Lee Vestry a resolution was proposed to the effect that the Vestry regretted to find that the Lee Board of Works had expended public money in actively opposing the light railway scheme of the London County Council from New Cross to Eltham, which the Vestry believed would have proved a great public boon and a sound and profitable investment of public funds. A long discussion ensued, and finally, on a division, eight voted for the resolution and 12 against.

Birmingham.—Work has been commenced at Bournbrook upon the equipment of the Bristol-road tramway as an overhead system. The rails are being bonded together, and the poles are being laid by the edge of the pathway ready for erection. The work of laying the electric cable will be undertaken by the Electric Supply Committee, and the Public Works Committee will have the supervision of the reconstruction of the lines in Bristol-street and the Horse Fair, where the use of the centre poles necessitates a wider space between the two sets of metals than at present exists.—*Birmingham Daily Post.*

Lewisham.—A letter from the London County Council with reference to the proposed tramway from Camberwell green to Forest Hill is being considered by the Works Committee. The London County Council are asking whether, upon a reconsideration of the whole subject, the District Board of Works could see their way to give their consent to the construction of the tramway along the portion of the thoroughfare within their district, and to contribute one-third of the net cost of the necessary street-widening in Lewisham. It appears that the districts through which the greater portion of the line passes have refused to contribute.

Glasgow.—The Tramways Committee have confirmed their previous decision in the matter of that part of the tramways report which had been referred back to them, and arranged that Messrs. Macartney, M'Elroy, and Co. should proceed at once with the erection of the overhead work for the tramway exten-

Digitized by Google

sions in Alexandra-parade, Cumbernauld-road, Keppochhill-road, and Great Western-road, and that the Lorraine Steel Company should proceed with their contract for the special track work, which is mainly for crossings. The proposal to apply for parliamentary powers to extend the tramways to Cambuslang, Renfrew, Clydebank, and Bishopbriggs has been adopted by the Council.

Traction Trucks.—We are glad to observe that English manufacturers are commencing active operations in the manufacturing of tramway materials. The Brush Electrical Engineering Company, Limited, have now taken up the manufacture of traction trucks at their Falcon Works, Loughborough, Leicestershire. They make three standard types, which cover the general needs of electric traction in this direction—namely, the four-wheel single type, the four-wheel bogie type, and the maximum traction type. A special shop has been erected and equipped under the control of Mr. E. E. Cook, an engineer who has had long and successful experience in this branch of manufacture in the United States.

Hampton Wick.—The District Council have adopted a number of recommendations of the Highway and Lighting Committee with regard to certain options which the Council have power to take under the recent Act of the London United Tramways. The paving from the railway station to Kingston Bridge is to be constructed of Jarrah wood blocks, and before the tramways are commenced notices will be issued to the owners and occupiers of houses along the route pointing out the desirability of renewing their service pipes from the water company's mains before the wood paving is laid, as the expense afterwards would be considerable, and that the attention of the gas company be also called to the matter.

London United Tramways.—The local authorities in Middlesex and Surrey have received notice of the company's intention to apply in the next session of Parliament for powers to construct additional tramways, including 23 miles of lines in Surrey, 20 miles in Middlesex, and 20 miles in the county of London. The existing system, under this scheme, will be extended to Fulham, Marylebone, St. Pancras, Putney, Willesden, Southall, and Sunbury. A new street and new bridge are included in the Richmond extensions. A number of lines are to give intercommunication between different parts of Kingston, Putney Hill, Surbiton, Tolworth, Hook, Long Ditton, Thames Ditton, Esher and Hampton Court, Brentford and Ealing, Twickenham and Kempton Park, Putney and Richmond, Hounslow and Cranford, etc.

Strikes.—There is, or was, a dispute between the Oldham, Ashton, and Hyde Electric Tramway Company and their employés. About 80 went out on strike, and the company were obliged to run a reduced service of cars in the daytime with the assistance of imported non-society drivers and conductors. The strike originated with the dismissal of a number of men who were on the maximum wage list without what was thought a satisfactory reason. The strikers have an organised system of picketing, and they have induced many men brought into Ashton to take service on "a new route" to return to their homes. Free labour was supplied fairly plentifully through a Manchester agency.—Last week all the men, numbering 500, employed at the electric car works, Hadley, near Wellington, Salop, recently removed from Birkenhead, came out on strike. The men have left their work to support 40 others who have been locked out during the past fortnight for objecting to the employment of unskilled workmen on certain machines at an alleged loss.

Stirling.—At the last County Council meeting, the committee appointed to enquire into the application for the consent of the Council to the construction of an electric tramway on a circular route between Falkirk, Carron, Stenhousemuir, and Camelon, reported the terms on which they were prepared to give their consent to the undertaking. First, the company to pay to the Council an annual wayleave of £40 per mile of route within the area of their jurisdiction, and to maintain the road between the rails and to the extent of 18in. on each side; or, second, to pay the Council at the rate of £72 per mile per annum, the Council maintaining the roadway, with the exception of the tramway rails and their supports. In any event the company at their own expense will construct the roadway with setts between the rails and on each side. Clauses were also inserted for the purchase of the undertaking by the Town and County Councils on certain conditions at the expiration of 25 years and other subsequent periods. It was stated that the line was a single one, with crossing places and that there was sufficient room on the roads for other traffic. The only difficulty was the canal bridges, and these were outside the county. The matter was left in the committee's hands.

East Ham.—The electrical engineer and the surveyor reported at the last meeting of the Urban District Council that the total extras in connection with the tramway track recently constructed by Dick, Kerr, and Co. were £1 682. 9s. 2d., which was due to the substitution of wood paving for tarred macadam, additional granite pitching, removal of gas and water mains, and the work in connection with the East Ham railway bridge, and which were not included in the contract. Also that an estimate had been received from the electrical engineer and the surveyor, together with the tender of Dick, Kerr, and Co., for the extension of the tramway track from the Denmark Arms, along the Barking-road to the Barking boundary, and from the north metropolitan sewer embankment to Cyprus-place, and the committee, having fully considered the same, recommended that the tender of Dick, Kerr, and Co. be accepted, subject to their agreeing to construct the portion of track across the Great Eastern Railway (Beckton line) after the sanction therefor has been received from the Board of Trade. The electrical engineer reported that the whole of the first consignment of cables had been laid, completing Forest-drive, Station-road, and Carlyle-road. He had tested about 6,500 yards of distribution cable, in the presence of a committee and councillors, to their satisfaction, at Messrs. Callender's works, and this was now on its way from the works to Romford-road, where it would be laid as soon as it arrived. The laying of the conduits for the lighting feeder cables at Plashet-grove was being proceeded with The whole of the tramways poles in High-street South and Barking-road had been erected, and the erection of poles in High-street North would be proceeded with at once.—*West Ham Guardian.*

Colonial.—We are indebted to the well-informed *New South Wales Railway Budget* for the following summaries: The Hon. J. L. Stirling moved the second reading of the Electric Tramways (Private) Bill (No. 1) in the Legislative Council of South Australia on July 11. During a lengthy speech, the hon. member stated that the object of the Bill was to attain the necessary powers to abolish the antiquated system of horse traction, and substitute the modern system of electricity. These powers were asked for by the Westinghouse and the Callender Companies, who had jointly secured the right to purchase 60 miles out of the 70 miles of the Adelaide and Suburban Tramways. To provide the city and suburbs with the intended conveniences, the companies claimed that it will be necessary to incur an initial expenditure for the purchase of the existing lines of nearly £400,000; and a further expenditure for the work proposed by this Bill, about another £400,000, which did not include the conversion of the whole of the lines. A sum of £8,000 had been paid to the Government as a guarantee that the work would be proceeded with. It was not proposed to make this a foreign company, as an opportunity was to be offered to the shareholders of the present companies to reinvest their money in the new concern. The debate was adjourned until July 17, and on the 18th the second reading was carried, and referred to a select committee.—Mr. W. Gentry Bingham, representative of the Electric Tramways Company, recently returned to Auckland to take up the work in connection with the Auckland electric tramways scheme. He states that the work of constructing the tramways will be put in hand as soon as ever the negotiations with the suburban authorities are completed. The equipment of the city lines will be undertaken without delay, and he considered it would be a great advantage to all parties if matters could be satisfactorily settled with the suburban bodies, so as to enable the completion of the scheme in one contract. The points at issue, with the exception of those raised by Newmarket, Mr. Bingham considered of minor importance, and, considering the sympathetic spirit in which he had always been met by the local bodies, he had every hope of being able to adjust them satisfactorily.—Several proposals for the construction of private railways are now before the Queensland Legislature. The Callide Coal Syndicate Railway Bill was read the first time in the Assembly on July 25. The company asks for power to construct and maintain a line of railway and branch lines to connect its land with Gladstone Harbour. The line is to be constructed within three years from the date of the passing of the Act, and is to be 75 miles in length; no branch line, however, is to be more than 10 miles long. The gauge is not to be less than 2ft.; the rails are to be of steel, and weigh not less than 35lb. to the yard. The Government is to convey over the public railways all material for the construction of the line at the rate of ½d. per ton per mile.

LIGHTING AND GENERAL.

Morley.—Several electric light cables are about to be extended.

Lytham.—The electric lighting scheme has been abandoned for the present.

Canterbury.—Further extension of the electric light works has become necessary.

Sudbury.—Application is to be made shortly for a loan for electric lighting works.

West Bromwich.—The report upon the free wiring, extracts of which appeared in our last issue, has been adopted.

Accrington.—The engineer's last report shows that there have already been received 33 applications, equivalent to 1,460 16-c.p. lamps.

Reuter's Telegram Co.—The directors announce an interim dividend at the rate of 5 per cent. per annum for the half-year ended June 30.

Watford.—Major Cardew is engaged in making a report upon electric lighting works and additional plant required by the Urban District Council.

Wireless Telegraphy.—The "St. George" cruiser has been fitted at Portsmouth with masthead semaphore and wireless telegraphy apparatus.

Shoreditch.—The insurance of the electricity and dust destructor works has been placed in the hands of the Fine Art and General Insurance Company.

Farnham.—A committee of the whole Council have considered the question of the provisional order for electric lighting, and the clerk is to make certain enquiries.

Bedford.—The public lighting of Devon-road with electric lamps is to be completed, and the cable extended so that 2 and 4, Peel-street may be supplied with electric light.

Molesey.—The Council have consulted Mr. Albion T. Snell with reference to the proposal of the Edmundson Electricity Corporation for supplying the district with electric current.

Digitized by Google

The Galveston Disaster.—The Western Union Telegraph Company announces that telegraphic communication with Mexico and South America *vid* Galveston is now completely restored.

Direct United States Cable Co.—The directors announce an interim dividend of 3s. per share, being at the rate of 3 per cent. per annum, for the quarter ended 30th ult., payable 26th inst.

Sale of Plant.—We beg to refer to an announcement which appears in another column for particulars of a sale of an electric installation by Messrs Galloways, Limited, Knott Mill Ironworks, Manchester.

Wicklow. — A letter from Mr. S. J. Warden-Stevens, A.M.I.E.E., of London, stating that he would prepare a report for the application of an order, etc., is before the Managing Committee of the Urban District Council.

Moffat.—Mr. W. J. Forman, electrical engineer, St. Leonards, Moffat, who is of opinion that an electric lighting scheme could be carried out with profit to the burgh for about £2,500 (water power being utilised), has been asked to prepare plans.

Brierley Hill.—The Midland Electric Corporation are progressing with the laying of the electric cables. They have given notice of intention to break up Bank-street, Dudley-street, High-street, Brettell-lane, Mount-pleasant, and other streets.

Pickering.—The question of making an application to the Board of Trade for an order to establish works for supplying electricity to the urban district was again discussed at the last Council meeting. Finally the matter was again deferred.

Stafford.—It is reported that about 80 acres of land have been bought near Stafford for the purpose of erecting large electrical works close to the main line of the London and North-Western Railway, and that when completed these works will employ over 1,000 people.

Beckenham. Judging from the progress of the works, it is expected that current can be supplied from the middle of November. The wiring rules have been adopted, with the proviso that 1s. 6d. per 8 c.p. lamp per annum be taken as the minimum payment for wiring.

Stratford-on-Avon.—The Town Council intend to oppose the application to the Board of Trade by the United Electric Light and Traction Company for a provisional order, the Council having decided to apply themselves for such provisional order to supply electricity within the borough.

Chefoo-Tientsin Cable.—The cable which was laid between Chefoo and Tsintau for account of the German Government was opened for the transmission of messages on Oct. 4. The territory of Kiao Chau is thus joined to the international cable system. No change will be made in existing rates.

Falkirk.—A special meeting of the Town Council is being called, on a month's notice, in terms of the Electric Lighting Acts, for the purpose of considering and, if so decided, of resolving to make an application to the Board of Trade for a provisional order for electric lighting.

Eccles.—There are now 8,044 lamps connected with the generating station, and the supply of the electric light last week was the highest on record. The Council have confirmed the appointment of Mr. H. W. Angus, late chief assistant to the Bolton Corporation, as their electrical engineer.

Bournemouth.—We understand that the Town Council have written to the National Telephone Company informing them that the Council are considering the propriety of applying to the Postmaster General for a license, and ask them if they are prepared to reduce their charges in Bournemouth.

St. George (Hanover-square).—A special meeting of the Vestry was held yesterday to receive and consider the report of the special committee of Vestry *re* electric lighting, recommending that the agreement between the Vestry and the Westminster Electric Supply Corporation be approved and sealed.

Banbury.—At the quarterly meeting of the Town Council, the question was raised whether the electric lighting scheme was progressing or otherwise. It was known that a company secured the provisional order some years ago, but no one seemed to have any further information about the point. The time limit must be nearly expired.

Oriental Telephone and Electric Co.—The directors have declared an interim dividend of 2½ per cent (being at the rate of 5 per cent. per annum) on the paid-up capital of the Company, free of income tax, payable to those shareholders whose names were on the register at Oct. 10. The warrants will be posted 31st inst.

Dudley.—Mr. H. Percy Boulnois, M.I.C.E., has held an enquiry into the application of the Town Council to borrow £10,000 for the purpose of defraying the cost of the free wiring of houses and business premises for electric lighting. It is proposed to charge 6d. per unit for the first two hours' consumption per day, and 1½d. per unit afterwards.

Consett.—The Urban District Council have adopted a recommendation to illuminate the streets by electricity and to provide a refuse destructor. The Council have also sanctioned, subject to certain conditions, the proposed application of the Northern Counties Electrical Supply Company for a provisional order in respect of the urban district.

Airdrie.—Draft agreements from the Scottish House-to-House Electric Company relating to the proposed transfer of the provisional order obtained by the Town Council for supplying electric light in the burgh, and also providing for the lighting of the street lamps and supply to private houses, etc., are under consideration by the Town Council.

Removal.—The old-established firm of Johnstone, Benjamin, and Co., late of Wenlock-road, City-road, have removed their offices and works to Crown Electric Works, Ascham street, Kentish Town, N.W., near to Midland Railway Station, where they have installed an entirely new plant for the manufacture of electric light cables in order to cope with an increasing business.

Meltham.—In consequence of a letter from Mr. A. H. Gibbings, M.I.E.E., consulting electrical engineer, Bradford, stating that a proposal was on foot for the forming of a joint electric lighting scheme for the districts of Slaithwaite, Linthwaite, Marsden, and Holmfirth, the Urban District Council have appointed a small deputation to confer with the representatives from the other Councils.

Appointments Vacant.—The Corporation of Motherwell invite applications for the appointment of burgh electrical engineer.—The electricity department of the Leyton District Council require a shift engineer. Full particulars of these vacancies appear in our advertisement columns.—The Corporation of Southampton require the services of a mains superintendent, at an annual salary of £150.—The Tramway Committee of the Manchester Corporation require the services of a lady superintendent for their ticket and cash counting department.

New Swindon.—Application is to be made to the Local Government Board for power to borrow £31,000 for carrying out the first portion of the electric light scheme for the town. That sum is £800 in excess of the engineer's estimate, and includes the purchase of all the engines and machinery necessary for both light and traction and the laying of the whole of the cables throughout the town. The steam dynamos will cost about £6,000, and the Council will advertise for three steam dynamos, as recommended by Mr. Lacey, so as to ensure early delivery.

Stock Exchange.—The Stock Exchange Committee have appointed Oct. 17 as a special settling day for St. James's and Pall Mall Electric Light Company's £150,000 3½ per cent debenture stock. The committee have also ordered the St. James's and Pall Mall Electric Light Company's £151,000 3½ per cent. debenture stock, and the Western Telegraph's Company's £348,777 4 per cent. debenture stock, to be quoted in the official list. The committee have further been asked to allow Folkestone Electricity Supply Company's 10,000 ordinary shares of £5 each, fully paid, Nos. 1 to 10,000 (renewed application), to be quoted in the same list.

Hornsey.—At the last meeting of the District Council a letter was read from the Board of Trade approving of the system upon which the Electric Lighting Committee propose to work. The Highways Committee reported having had before them a letter received from the Board of Trade enclosing a copy of Colonel Yorke's report on his inspection of the Highgate hill tramway, and also a copy of a letter received from Messrs. Weekes and Co., instructed by the tramway company, as to the cost of repairing the roadway, and stating that the Board of Trade had consented to the use of cable traction on the tramway for six months from Sept. 12

Paisley.—The Town Council have received a report from Mr. J. Balderston Whyte, C.A., relative to the financial condition of the electric lighting works, stating that the capital expenditure till date is £94 832. 15s. 1d., after allowing a margin of £500 for contingencies or £14 832. 15s. 1d. in excess of the present borrowing powers. No allowance has, however, been made to cover the cost of laying additional mains and connections. He adds that he is informed that the three engines supplied by Ferranti, Limited, are to be removed, and two engines are to be supplied of equal capacity, without further expense to the Corporation. A further report on the subject, including a tabulated statement of the original estimates showing additions to each department since these were accepted, and whether these additions were necessary or for ornamental works, will be prepared.

London Gazette.—A receiving order has been made out *re* W. Haines, 261, Bury New-road, Whitefield, Lancashire, on debtors' petition. The first meeting in the estate of the above will be held on Oct. 16 at the official receiver's office, Exchange-street, Bolton, at 11 a.m., and the public examination on Oct. 23 at the Court House, Mawdsley-street, Bolton, at 3 p.m.—The first meeting in the estate of T. W. Greaves and W. G. Randall (lately trading as T. W. Greaves and Co., 230, East India Dock-road, E) will be held on Oct. 18, at 1 p.m., at Bankruptcy-buildings, Carey-street, W.C., and the public examination on Nov. 15, at 11.30 a.m., at Bankruptcy-buildings, Carey-street, W.C.—A first and final dividend of 2s. 5½d. per £ has been declared *re* B. Symmons (trading as B. Symmons and Co.), 2, North-street, Quadrant, Brighton, payable at the offices of Ward and Wilding, 17, North-street, Brighton, from Oct. 11.

Sunderland. — The Lighting Committee's report, the first portion of which recommended the recision of the minute passed by the Council as to inviting competitive designs for a new electric lighting station in Hylton-road has been adopted. It was explained that Mr. Snell, the electrical engineer, had himself prepared a plan for the erection of a station, which was so satisfactory, and which seemed to meet all requirements, that the committee had considered that the Council need not be put to the expense of engaging an architect. The Council on Wednesday authorised the committee to borrow £73,035 with which to construct the new electric lighting supply station at Hylton-road, carry out extensions of mains, and other purposes. It has also been decided that, except on special contracts, customers should have the option of being charged according to the maximum demand system, or at a uniform rate of 5d. per unit with a scale of discounts, the rental of meters also being reduced in proportion.

Digitized by Google

Hastings.—Electric light mains are to be laid in the undermentioned roads: Linton-road, estimated cost £208; St. Saviour's-road, £251; Sedlescomb-road, £295; Sedlescomb-road (high-tension main), £120; St. Matthew's-gardens, £140; Boscobel-road, £135—total, £1,149. Application is to be made to the Local Government Board for sanction to the borrowing of the total estimated cost of the work.

Ashton.—A presentation of plate has been made to Mr. Vincent, the chief engineer, who has just returned from his holidays, and also his honeymoon, he having been married during his leave of absence. Mr. Bruton, first assistant engineer, formally made the presentation, which was seconded by Mr. Markland, second assistant engineer, and most heartily endorsed by the whole of the staff present, to the number of 20.

Cardiff.—The gas company are going to raise their price. The Corporation propose to issue circulars with a view of making the electric light much more popular as an illuminant, setting out the advantages of this particular light. The consideration of the report from Mr. Appelbee upon the arrangement of the electrical staff has been deferred. The Chairman stated at last week's meeting that everything was proceeding smoothly at the electricity works.

Much Woolton.—A draft agreement with the National Telephone Company for laying underground cables in the district was submitted to the District Council last week, also a letter regretting the company's inability to agree to certain clauses inserted by the Council. It was resolved that negotiations cease, and that the clerk be instructed to ascertain from the Bristol Corporation the terms upon which the Telephone Company are permitted to lay cables under the roads in their district.

Islington.—The Vestry having decided to light Hornsey-road and Drayton-park with electric arc lamps, it is considered advantageous to continue the lamps from Hornsey-road along Benwell-road to Drayton-park. The engineer's estimate for the work is £1,450, and we understand that the work of laying and erecting conduits, cables, four arc lamps, columns, etc., included in the estimate, will be carried out after the usual consent to the borrowing of the necessary funds has been received from the London County Council, and that a loan is to be raised for the purpose.

Worcester.—A resolution concerning the supply of electricity to churches and chapels led to an animated discussion at the last City Council meeting. The Chairman of the Electricity Committee, in moving 'That the Council be recommended, as from Sept. 29 next, to fix the price for current supplied to churches and chapels at 5d per unit, on the understanding that as far as possible the current is not used during the time of the highest load, between 5 and 7 p.m.," said the transaction was a purely business one, the object of the committee being to increase the users of the electric current on Sunday. The resolution was lost.

Bury St Edmunds.—Sanction has been obtained to the borrowing of £800 for the purpose of public electric lighting, provided no part of the loan be employed in providing incandescent lamps. The engineer is taking steps to procure the necessary cable and lamps for public street-lighting. Two five-ampere arc lamps are to be fixed at the waterworks yard, each having an illuminating power of 500 candles. Below the arc lamps, two small incandescent brackets will be placed for the purpose of lighting the yard when only a small amount of light is required. The cost of lamps and wiring is estimated at £15. 10s., and the annual cost of lighting at £5.

Crook.—Messrs. Pease and Partners, Limited, are taking steps for the laying down of an electric installation. The Council have accepted their offer of 35s. per lamp for public lighting, the firm taking all the expense of the initial cost. Most of the lamps are to be 32 c.p. Apart from the occasional renewal of the lamps and the cost of cleaning, the charge of 35s. will cover the entire expense per lamp. The district to be lighted is Institute-terrace, White Lea square, Billy-hill, the whole of the houses on the hill top up to the junction by the Stanley Church. Messrs. Pease and Partners will place their generating station at the general shops.

Bermondsey.—A tablet is to be placed in the chimney shaft at the electric lighting station, bearing the following inscription: "This stone was laid by Thomas Cox, chairman of the Electric Lighting Committee, September, 1900. Committee: J. B. Anderson C. E. Barber, A. Burton. H. Gardiner, G. H. W. Grace, W. J. Hollies, J. Manser, G. W. Marner, J. R. Martin, G. W. Mitchell, J. J. Paice, H. C. Rogers, H. A. Rye, G. Simpson, T. Taylor, H. Walker, N. Wells, J. H. Wilkinson, Felix T. Pridmore, J.P. (chairman Bermondsey Vestry). Kincaid, Waller, and Manville, engineers. Hughes and Stirling, builders. Fredk. Ryall, clerk to the Vestry.

St. Marylebone.—At a meeting of the Vestry yesterday a report was submitted by Advisory Special Electric Lighting Committee recommending that the Vestry withhold their consent to the execution of the works referred to in the notice from the Metropolitan Electric Supply Company of their intention to lay a low-tension armoured main along the east side of Edgware road, from north side of Seymour-street to south side of Bryanston-street; from No. 84 to south side of Upper Berkeley-street; and from north side of Burwood-place to north side of Nutford-place, crossing at north side of Seymour-street, south side of Upper Berkeley-street, and north side of Burwood-place.

Middlesbrough.—At a recent meeting of the Electric Lighting Committee of the Corporation, Mr. Hammond, the consulting engineer, laid a plan before the committee showing the positions of 40 suggested lamps in the Market-place, South-street, Sussex-street, Linthorpe-road, Newport-road, Corporation-road, and Albert-road, which would do away with 147 existing lamps. The gas lighting costs £782. 0s. 8d., and 40 lamps, with half of their number turned out at 12 o'clock at night, at a charge of £20 per lamp, would cost £800 per annum, which was practically the same. The committee decided to make such an offer to the Watch Committee. Mr. Clayton, clerk of the works, was appointed as resident engineer.

A Find.—The following story has been going the rounds of the Press: "A conductor on the Venetian electric trams named Nicola Cicchino has just had a great stroke of luck. In July, 1898, he found in the Via San Lorenzo a draft for £10,700 on the Marseilles Land Bank, payable to bearer in gold. It was signed 'Attanasio.' Cicchino deposited the cheque with the authorities, awaiting the appearance of the owner to claim his legal 10 per cent. The owner, however, has never appeared, and a few days since Niccola received an official notification that the cheque, having never been claimed, was now by law his property." It is, however, not stated whether the cheque has not been stopped at the bank, nor whether there were any funds to meet it.

London County Council.—The first meeting of the Council after the summer recess was held on Tuesday at the County Hall, Spring gardens. Upon the recommendation of the Finance Committee it was agreed to lend the Islington Vestry £3,187 for the purchase of electric light meters, and the Battersea Vestry £5,145 for arc lamps and standards. The Fire Brigade Committee recommended that the tender of Mr. F. J. Coleby to maintain for three years after the expiration of the current contract the electric bells belonging to the fire brigade and the telephone installation at the chief station be accepted, the price to be paid being £315 per annum for the number of bells existing on Oct. 3, 1900; and that no additional charge be made for the use of the combined bell and electric light call switches at any station.

Birkenhead.—That portion of the corporate estate entrusted to the Gas, Water, and Electrical Committee was inspected on Saturday by the members of the Council entrusted with its control, and as their guests were also the chairman of other committees and leading officials. At the electrical generating station in Bentinck-street was made obvious the rapid development of this branch of the department. An engine of 500 h.p. had got to work for the first time, and at the back of the works was found rapidly springing to completion the new stations for supplying energy for the electrical tramways. Mr. Bates and Mr. Shallcross accompanied the party over the works, lucidly explaining a somewhat complicated branch, and later at Flaybrick-hill they conducted the company through the new generating station now supplying Noctorum and Bidston with the electric light. At the conclusion of the inspection, dinner was served at Flaybrick-hill waterworks, and at which Alderman H. Bloor presided. The usual toasts were proposed and duly honoured.

Lowestoft.—The last report of the Electric Lighting Committee states that, in reference to Mr. Hawtayne's report on the cost of a complete system of public lighting by electricity of the borough, instructions were given to Mr. Hawtayne as to the revision thereof (in conjunction with the borough surveyor), he to submit his revised scheme to a further meeting of the committee. Mr. Hawtayne was also requested to report to the committee as to the substitution of electric motive power for the gas-engines now in use at the pumping station. The surveyor was directed to furnish to the committee a complete report upon the number of public lamps in the borough, and the cost of public lighting by gas, to be considered in connection with Mr. Hawtayne's revised report on public electric lighting. Thirty-six applications have been received for the post of resident electrical engineer. The demand for electricity is proceeding very satisfactorily. There are now 2,271 private premises wired and fitted up, and it is expected that the lighting of the borough will be an accomplished fact by the middle of December.

Sunbury.—The District Council have adopted a report of the General Purposes Committee on the draft order submitted by the Twickenham and Teddington Electric Supply Company stating that (1) the Council were empowered by the order to carry out, at the expense of the company, the works of excavating and reinstating the roads and footways necessary for the undertaking, but the committee do not recommend that the Council take advantage of this provision. (2) The order provides that the company shall, within two years from the date thereof, lay sufficient mains in part of the district to be defined in the order and called "the compulsory area." The committee recommended that the compulsory area for this district be the lighting district, and that the company be requested to insert a provision to this effect in the provisional order. (3) The committee also considered as to the terms of the order with respect to purchase by the respective local authorities, the price of electricity, and other provisions general to the whole of the urban districts included in the order, and they recommended that the clerk write to the other local authorities concerned, to ascertain whether they wish to obtain any amendments of or alterations in the general clauses of the provisional order, and decided to defer further reports until the receipt of the answers to the enquiry.

Stroud (Gloucestershire).—A special meeting of the Urban District Council was held last week to consider the desirability of applying for a provisional order for the electric lighting of the district. It was stated that a private company was about to apply for power to light the district, and if the Council obtained a provisional order now they would protect their own rights. Mr. English thought the question to be decided now was whether they wanted the electric light or not. The Chairman said they might

Digitized by Google

obtain the powers now, and take action in the future. It was further said that to light the town of Stroud they would require a minimum of 5,000 incandescent lamps at a cost of not less than £3 per lamp. Probably they would require 10,000 lamps, so that they would have a capital expenditure of £30,000. That was a large sum for Stroud, practically equal to the whole of their assessable value. Other speakers were strongly in favour of the introduction of electric light. It was urged that they could protect themselves, and begin work for an expenditure of £150 or so; it would not be thrown away, and they would have the right to carry on the work when circumstances were more favourable. The tradespeople in the town were practically unanimous in favour of the electric light. The ratepayers of Stroud were greatly dissatisfied with the present lighting of the town. The meeting was adjourned for a fortnight for the purpose of further considering the matter.

Colchester.—The Electric Light Works Committee recently met at the electricity station, and inspected it and the plant, and expressed their satisfaction with the general condition thereof. The new engine at the time of inspection was running at 240 h.p., and 3,100 lamps were being supplied with current. The new boiler will shortly be ready for delivery. The recent temporary partial failure in the supply of current arose through a loss of steam in the early part of the evening, which could not be recovered owing to the fact that one boiler only was available, the No. 2 boiler being under repair (recaulking), and the intended No. 3 boiler not yet delivered. The partial failure was remedied within a comparatively short time, and no similar one is apprehended. From the minutes adopted last week we gather that Messrs. Siemens Bros. and Co. wrote that if the whole order for the 1½ miles of new feeder cable for the Sobraon and Goojerat barracks be given at once, they will adhere to their original quotation of 9s. per yard. The chairman reported that in the circumstances he deemed it prudent to order the cable, and his action was confirmed. The surveyor was requested to report upon the question of the committee bearing part of the additional cost to be incurred by the Roads and Drainage Committee in laying slabs in the pavements in certain streets so as to facilitate the laying of cables thereunder whenever needful. The electrical engineer submitted applications from three owners of premises in Maidenburgh-street for current for a 2-h.p. motor, and a total number of 36 16-c.p. lamps, and stated that the cost of laying a cable 150 yards long would be £54. 7s. 6d. It was resolved that, subject to the Council's approval, the cable be laid, the committee being fully satisfied that the demand for energy is sufficient to justify the expenditure. It was also resolved that three prepayment (slot) meters be purchased at £3. 10s. each.

Price-List.—We have received from the Sunbeam Lamp Company, of Gateshead-on-Tyne, an abridged edition of their catalogue of Sunbeam lamps. The book is very neatly got up, and is thumb-indexed, so that one can open it at any particular place. It will be found very useful to carry in the pocket for reference when ordering lamps, and in this way possesses a great advantage over a full catalogue. Amongst the reasons put forward as to why Sunbeam lamps should be used in England is, we are pleased to note, that they are made in England, by English workpeople, of English material, and with British capital. The lamps have, we learn, been adopted for the Houses of Parliament, and also by the Admiralty, General Post Office, etc.—We have also received a pamphlet setting forth the advantages of the Renewable Electric Lamp Company's goods. This company, whose offices are in City-road, make their lamps with a rather long neck to the bulb, and when a filament becomes burnt out the glass neck of the bulb is cut and a new filament inserted, the lamp being closed and exhausted in the ordinary way, and it is then fit for use again. It is interesting to note that the price for the renewal of a lamp is just half of its original cost, this being a great saving where many lamps are used.—Mr. G. Braulik has also sent us an illustrated sheet dealing with the patent arc lamp couplings, of which he makes a speciality. These patent couplings prevent the untidy appearance which loose wires give to an arc lamp. The coupling has also the advantage that when a lamp is pulled down for recarboning it is cut out of circuit, and there is thus no danger of shock. The price charged for these couplings is 35s. each.—We have received also a card from Messrs. Johnson and Phillips setting forth the sizes, weights, resistances, etc., of their electric supply main cables. These range from conductors of ·05 square inch section to one square inch.

Bradford.—At the meeting of the Town Council on Tuesday the following report, for which we are indebted to the *Bradford Observer*, was adopted: "Mr. T. H. Shaw, chairman of the Electricity Committee, moved the minutes of that committee, and in doing so read the report of the work of the electricity department during the half-year ended on June 30 last. He stated that the total income for the half-year was £17,723. 9s. 5d., as compared with the corresponding period in the preceding year of £13,256. 12s. 11½d., or an increased income of £4,466. 16s. 5½d. The total expenditure for the half-year (including interest and sinking fund) was £16,751. 1s. 3½d., as against £11,523. 10s. 4d. for the corresponding period of the preceding year. The net profit for the half-year, therefore, was £972. 8s. 1½d., as against £1,733. 2s. 7½d., being a decrease of £760. 14s. 6d. on the corresponding period of the preceding year. The number of consumers was 1,178 as against 965, or an increase on last year of 22 per cent. The total number of units consumed was 1,449,409, against 996,807, or an increase of 45 per cent. (irrespective of current supplied for public lamps). The total profit since the opening of the electricity works (in September, 1890) to June 30, 1900, after paying interest and sinking fund, amounted to £26,986. 0s. 6½d., and the total amount written off for depreciation has been £14,372. 17s., leaving the sum of £12 613. 3s. 6½d. to be appropriated as the Council might direct. The trade profit—that is the profit before charging interest and sinking fund—for the half-year ended June 30, 1900, worked out to £3. 7s. 2d. per cent. on a capital outlay of £241,838. 8s. 11d., and the net profit—i.e., after charging interest and sinking fund—shows a percentage of 8s. on the same outlay. Taking the June half year and the preceding December half-year together, the trade profit amounted to £18,186. 14s. 1d., representing £7. 10s. 5d. per cent. on the capital outlay. The net profit for the same half-years amounted to £4,369. 13s. 10½d., and represented £1. 16s. 2d. per cent. on the capital outlay.

COMPANIES' MEETINGS AND REPORTS.

NEWCASTLE ELECTRIC SUPPLY.

An extraordinary general meeting of the Newcastle-upon-Tyne Electric Supply Company, Limited, was held on Oct. 4 at the offices of the Company, 50, New Bridge-street, Newcastle.

Alderman T. G. Gibson presided, and moved the adoption of a resolution to change an article in the Company's articles of association so as to empower the directors from time to time, and at any time, to appoint any shareholder to be a director, but so that the total number of directors shall not at any time exceed 12. He said two sites had been secured on the riverside at Wallsend. Of course, they could not take advantage of those two sites without agreeing with the Wallsend Urban District Council and the Wallsend Gas Company, but they had been able to make satisfactory arrangements with both of those bodies, and they now had power by Act of Parliament to build for the supply of electric energy for lighting and power for the district described in the map. The sites were advantageous for the purpose, being well situated for the Gosforth district and the east end of the town.

Dr. Mers seconded the resolution, and it was unanimously agreed to.

The **Chairman** said the directors at the present time had had the subject of tramways under consideration. It was in connection with the Newcastle trams, and would cover the country between Newcastle and North Shields. With this object in view they had formed a private syndicate to apply to Parliament for the necessary powers. He asked the Company's approval of the appointment of Sir Lindsay Wood and Mr. J. H. Noble as additional directors.

Sir Riley Lord moved the approval of the Company, and **Mr. Monorieff** seconded.

NEW ST. HELENS AND DISTRICT TRAMWAYS.

The first annual meeting of the shareholders in the new St. Helens and District Tramways Company, Limited, was held at the Law Association Rooms, Cook-street, Liverpool, on Oct. 8.

Mr. John A. Willox, M.P., who presided, shortly reviewed the object and work of the Company. The Company was formed to take over the business of the old company who had worked the tramways of St. Helens with steam haulage, and also to acquire from the Corporation of St. Helens the working of the new and extended system of electrical tramways which they were constructing. The Corporation undertook to lay down the rails and the electrical equipment and to supply the motive power, while the new Company was to provide the rolling-stock and the staff for working on the lines. At the outset the Company was at some disadvantage financially, as it had to pay rent, but was not in a position to recoup itself by the revenue arising from traffic. Seven months after the Company came into existence their first electric section was opened—namely, that between St. Helens and Prescot. Since then other sections had been opened, and the work was being pressed forward vigorously. At the date of the report, June 30, only about one-half of the tramway system had been completed, but since then other sections had been finished and opened, and they hoped that in a comparatively short time fully 20 miles of rails would be available. The delays at St. Helens might no doubt have arisen from unavoidable causes, but the result had been rather hard on the Company. They had been paying rent, providing rolling-stock, and incurring all the charges of administration, and had not been able to recoup themselves by the receipts from traffic. Now they might look with confidence to the whole system being brought into working order and producing a favourable revenue within a reasonable time. They had such an abundant stock of cars already on hand that they were in a position to commence the service whenever the lines were ready for use, therefore there would be no delay on their part in utilising the lines. The cars had given entire satisfaction to the travelling public, and the service had been maintained on all the routes with regularity. It was only right to give a word of praise to the Corporation for the excellence of their supply of power, which had been adequate and uninterrupted, and the efficiency of the Company's service had been largely due to this fact. The receipts on the various sections now in use were large and progressive, and realised the expectation of the directors. They might, therefore, look with confidence to the future, both as to the carrying power of the Company and the profit on the business. An important factor would probably be the South Lancashire Tramway Company. Parliament had sanctioned the construction of an elaborate system of electric tramways in the populous

Digitized by Google

district between Liverpool and Manchester for passenger and goods traffic. The St. Helens tramways would be an essential link in this important network of cheap locomotion, and it would be the policy of the Board to encourage its development, knowing that it would be advantageous to the public and to the Company. They had assumed no financial obligations in relation to the South Lancashire scheme, but they would be glad to handle any traffic which it might bring them, and to facilitate its development in any reasonable way.

Councillor H. Martin, J.P., seconded the motion, which was adopted without discussion.

Alderman Lloyd Higginbottom (Manchester), the retiring director, was unanimously re-elected, as were also the auditors, Messrs. Chalmers, Wade, and Co., of Liverpool.

On the motion of **Councillor Martin**, and seconded by **Mr. J. Atherton**, the chairman was thanked for presiding and for the manner in which he had conducted the business of the Company.

TYPEWRITING TELEGRAPH.

The first ordinary general meeting of this Corporation was held at Winchester House, Old Broad-street, on Oct. 4.

Sir James Fergusson, chairman of the Company, presided, and said that that was the first (or statutory) meeting since the incorporation of the Company, and the financial position was that 26,800 shares had been taken up and allotted, making available £15,000 clear for the development of the business of the Company. That would be quite sufficient, because they did not require a great deal of capital to carry on the business, as the General Post Office and the National Telephone Company were very large customers with them, and paid for the instruments as they acquired them. Negotiations were in progress for the sale of certain of the patent rights, including those for America, Germany, South Africa, France, and Scandinavia, the profit in respect to which would come entirely to this Company, because they had acquired the whole of the patent rights. Enquiries were being received for installations, which would be fitted as fast as the instruments could be supplied. Contracts with the General Post Office and the National Telephone Company were being completed, and would in all probability be sealed immediately. He had confidence as to the success of the extremely clever invention which the Company possessed, and he had been approached to take the position of chairman, he being a director of the National Telephone Company, which was one of their chief customers. He hoped and believed that profitable results would accrue to the shareholders from their investment in the undertaking.

Mr. Crouch asked whether the total subscribed was 26,800 shares and the working capital £15,000.

The **Chairman** said that was the amount of the subscription; as the shareholders would be aware, a portion of the purchase money was paid in shares. The total number of shares issued was 71,000, leaving a balance unallotted of 29,000.

Mr. Crouch said that he presumed, therefore, that they would have to pay dividend on the 71,000 shares, and he would like to know whether it was contemplated to begin to do so soon.

The **Chairman** said not before the expiry of six months.

Mr. John A. Sillars, chairman of the vending company, said that his company's rights had been perfectly satisfied, and he had to congratulate the shareholders.

Mr. Mordey, the Company's consulting engineer, gave a technical description of the machine owned by the Company, and pointed out that it could be used in conjunction with the telephone, and that it had the advantage of setting down in writing the essentials of a telephone message, and, moreover, an additional advantage was that messages in foreign languages could be recorded in plain writing.

A vote of thanks to the chairman closed the meeting.

PROVISIONAL PATENTS, 1900.

October 1.

17379. **Improvements relating to electric meters.** Henry Harris Lake, 45 Southampton-buildings, Chancery-lane, London. (Société pour L'Exploitation des Compteurs Electriques Rettener et Cie., Switzerland.)

17399. **Improvements in or relating to electric arc lamps.** Charles Oliver, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

October 2.

17437. **Improvements in telegraphones.** Edward C. Paramore, 111, Hatton-garden, London. (Complete specification.)

17453. **Improvements in and relating to electric perforating and recording machines.** George Howlett Davis, 77, Chancery-lane, London. (Complete specification.)

17467. **Improvements relating to telephone switchboards.** Henrik Tore Cedergren and Askar Kahr, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17475 **Improvements in and relating to the manufacture of substances similar to indiarubber.** Carl Adolp Resen Steenstrup, 322 High Holborn, London. (Complete specification.)

17479. **Improvements in automatic releasing mechanisms for phonographs and the like.** Julius Wall, 6, Lord-street, Liverpool.

17487. **Improvements in dynamo-electric machines and motors and in means for regulating the same.** Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

17489. **Improved electrical apparatus for automatically playing violins and the like instruments.** Arthur Douglas Douglass and Norman Collins, 53, Chancery-lane, London.

17490. **Improvements in the manufacture of secondary battery plates.** Berthold Kuettner, 37, Chancery-lane, London.

17496. **Improvements in and relating to ceiling roses and terminals for electrical lamps and power installations.** Hugo Hirst and Henry Bevis, 165, Queen Victoria-street, London.

October 3.

17507. **Improvements relating to electric lanterns to be fixed on the top of posts.** Harold Faraday Proctor, City Electrical Engineer's Office, Temple Backs, Bristol.

17514. **Improvements in electric switches.** Edward Woodrowe Cowan and William Pancras Hamlyn, Springfield-lane, Salford, Manchester.

17549. **Improvements in electrically operating signal bells and apparatus for that purpose.** Paul Millington Jerrard, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17568. **Improvements in or relating to prepayment mechanism for electric meters.** Thomas Herbert Minshall, 322, High Holborn, London.

17575. **Improvements in electric converters.** Frederic de Mare, 72, Cannon-street, London.

October 4.

17598. **Improvements relating to lanterns for gas or oil lighting to be placed on the top of posts for street lighting or the like.** Harold Faraday Proctor, City Electrical Engineer's Office, Temple Backs, Bristol.

17635. **Apparatus for automatically turning on gas should the current fail in a place electrically illuminated.** George Calvert and Reginald Morrell, 166, Fleet-street, London.

17642. **A new or improved instrument for measuring direct or alternating currents and potential differences.** William du Bois Duddell, Norfolk House, Norfolk-street, Strand, London.

October 5.

17670. **An improved method of combining a telephone with a system of electric bells.** Herbert Alexander and Archibald Duncan Hunter, 28, New Bridge-street, London. (Complete specification.)

17675. **Improvements in systems of electrical distribution.** Charles Ira Young, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, March 6, 1900, being date of application in United States.)

17694. **Improvements in or relating to the attachment of arc lamps to their weather-hoods or supports.** Charles Oliver, Birkbeck Bank chambers, Southampton-buildings, Chancery-lane, London.

October 6.

17715. **Improvements in torpedo steering, an appliance to permit of wireless telegraphic influence being received by submerged torpedoes for steering or other purposes.** Cecil John Varicas, 27, Avenue-road, Weymouth.

17722 **Improvements in or in connection with electric light fittings.** Clarence Metcalfe Stead and Frederick Scott, 30, Park-row, Leeds.

17723. **An improved fitting for incandescent electric lights.** Clarence Metcalfe Stead and Frederick Scott, 30, Park-row, Leeds.

17724 **Improvements in dynamo-electric generators.** Cyril Talworth Batchelor, 104, Colmore-row, Birmingham. (John George Herbert Batchelor, Brazil.) (Complete specification.)

17757. **Improvements in and relating to electrode plates.** William Phillips Thompson, 322, High Holborn, London. (The Akkumulatoren und Elektricitats-Werke Aktien Gesellschafo, vormals W. A. Boese und Co., Germany.) (Complete specification.)

17765. **An improvement in connecting the glow bodies of incandescent electric lamps to the leading-in wires.** Paul Scharf, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

17773. **Improvements in alternating-current electric generators.** Sebastian Ziani de Ferranti, Hollinwood, Lancashire.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Oct. 27.

1899.

15895. **Magnetic compasses.** Haddan. (Heit.)

19785. **Electro-chemical process for cleaning metal surfaces.** Vereinigte Elektricitäts Actien-Gesellschaft and Klandy,

NOTES.

Glasgow and West of Scotland Technical College Society.—The opening meeting of the session of this society is to be held to-morrow (Saturday) in the large hall, 38, Bath-street, Glasgow, when the president, Mr. David Home Morton, will deliver his inaugural address on "The Standardisation of Machinery." This is a subject which is very interesting to all engineers, and the opening meeting should for this reason be well attended.

Institution of Junior Engineers.—The annual general meeting of this institution is to be held next Friday, Oct. 26, at the Westminster Palace Hotel. This meeting opens the session 1900-1901. On Saturday a visit to the London Hydraulic Power Company's station has been arranged. Sir Lowthian Bell, Bart, F.R.S., of Northallerton, has, we are informed, been elected president of this institution, in succession to the Hon. C. A. Parsons, F.R.S., of Newcastle-upon-Tyne.

Electrical Apparatus in Brazil.—A gentleman bearing the high-sounding name of Dr. Olympio De Assis, of Minas, Brazil, has written, stating that in his town some electric railway lines are to be constructed, and he requests manufacturers of electrical apparatus and of other kinds of street railway material to let him have price-lists, catalogues, and any other information they may care to supply. The request was originally sent to American firms, but there should also be a chance of some of our English firms securing contracts, if these latter are worth having.

Compensation.—A subject which has not been much in evidence lately is now again to receive attention, this being the question of the compensation to be paid to the church authorities of St. Mary Woolnoth with respect to the City and South London extension to Moorgate-street. The company, it will be remembered, made use of the church during the construction of the line, and a claim is now being made for rent. The case is to be heard before Mr. Robt. Vigers at the Surveyors' Institution, and the *City Press* considers that the amount of compensation awarded will amount to several thousand pounds.

The Alaskan Cable.—The laying of the cable from St. Michael to Unalakleik, Alaska, has been seriously hindered by the cable ship "Orizaba," which was engaged in laying it, stranding upon a rock, which was apparently uncharted. The ship stranded on the afternoon of Sept. 20, and is probably still aground. Vessels have been sent to the rescue of the steamer, and they will probably take off the crew and the cable material and apparatus. The master of the "Orizaba" is of the opinion that the ship can be saved, but the mishap will prevent the completion of the Behring Sea cable this year. The total length of the cable when finished will be 187 miles, of which five had been paid out at the time of the accident.

Clapham Junction.—There are, we learn, improvements about to be effected at Clapham Junction, amongst which figures an electrical indicator denoting the platforms from which the trains are to start. This improvement, if carried out, will, we are sure, save a large amount of the time and energy which is now wasted by passengers at that station in hurrying from one platform to another asking which their train goes from. Every railway official tells one a different platform, and the subway in the station is frequently crowded with people trying to catch a train which apparently goes from two or three platforms at the same time. However, let us hope that with the advent of the electrical indicator this waste of time and energy will be prevented.

Society of Model Engineers.—The monthly meeting of the Society of Model Engineers took place on Tuesday, Oct. 9, in the Memorial Hall, Farringdon-street, E.C., about 50 members and friends being present. The Chairman drew attention to the new curved portion of track made by Messrs. Burnham and Orford, and the tool and buffer box constructed by Mr. H. S. Boorman. The formal business terminated at 8 o'clock, after which the trials of locomotives took place over the new extended track. The next meeting of the society, to be held on Thursday, Nov. 8, will be the annual general meeting, when will take place the election of new officers for the next session and other business.

St. Marylebone Lighting.—The Metropolitan Electric Supply Company do not seem entirely to have got rid of the obstruction which the St. Marylebone Vestry have offered to their works. Thus we notice that the Advisory Special Electric Lighting Committee of the Vestry have recommended that the Vestry shall withhold their consent to the execution of works referred to in a notice from the Metropolitan Electric Supply Company of their intention to lay a low-tension armoured main along certain roads in St. Marylebone. The refusal to consent to the laying is apparently only an outcome of the old quarrel existing between the company and Vestry. It is a pity that a body of men chosen to look after the interests of the public and a parish should put aside these interests in order to indulge in petty spite, which would appear to be the case in this instance.

The Central London Railway.—The directors of the Central London Railway are not, it would appear, slow in learning a lesson, and the recent unfortunate accident has already produced its results. Thus, one theory as to how the unfortunate man, Field, met his death was that he was knocked off the train whilst endeavouring to look through the windows at the side to see if anyone was smoking in the non-smoking compartment. The directors have now taken measures to prevent an accident again occurring from such circumstances, and are placing in the doors which shut in the carriages glass in the upper panels instead of the wood previously used. It is thus possible in the trains which are fitted with glass to look from one end of the train to the other. Apart from questions of safety, the glass panels with the neat monogram in the centre tend to improve the appearance of the carriages.

Victorian Water Power. — The question of the utilisation of the waterfalls in Victoria for the generation of electrical energy having been raised, Mr. Jas. Stirling, the Government geologist, has in his report for March given a list of the waterfalls which have come under the notice of the officers of the Geological Survey. The list gives the name of the falls, the locality in which they are situated, and the height of the fall. The fall having the greatest drop is the Yarra Fall, which has a drop of about 1,000ft. The next highest fall is one on the Dondangadale River, which drops some 400ft. The height of the other falls ranges between 300ft. and 28ft. Some of the streams are liable to cease running during very hot periods, but the majority of the streams are perennial. Several of the water-supply weirs could, we learn, well be used to store water for the generation of electricity, and one of them—the Goulburn weir—actually is used to generate electricity for lighting purposes.

Fuel Gas.—The *Trade Journals' Review*, in its issue for Oct. 5, has a leader dealing with fuel gas and its use for driving various plants. Our contemporary goes on to

Digitized by Google

explain that fuel gas is not illuminating gas, and speaks of its great use for driving small electrical plants. The fuel gas spoken of is producer gas, which is said to contain 80 per cent. of the heat energy of the coal consumed. A producer gas plant can be installed for about the same cost as a steam plant of the same capacity, and its performance is said to be better than that of steam. Tests are stated to have shown that the same result can be obtained with producer gas with half the amount of coal required for steam plants, the coal also being of an inferior quality. Our contemporary, however, while not doubting that the power gas will replace steam in a very large number of cases, does not go to the extreme of stating that the steam-engine will become defunct, but thinks that steam must for many years hold its own in certain circumstances, such as ship propulsion, etc. The real trouble with the use of fuel or power gas appears to be with the maintenance of the gas-engines and plant.

Electromobiles in France.—We gather from the French Press that the Touring Club of France is compiling a card of electric stations in that country at which electromobiles can be charged, and has sent to private persons owning electrical installations a number of questions as to the nature of the current produced by their machines, whether continuous or alternating. If the current is alternating, whether they have transformers to obtain continuous current? If the voltage is continuous, what is the voltage? They also ask if the owners are willing to sell their current for recharging electromobile accumulators, and how many amperes they are willing to dispose of, and at what hours? It is also asked if ampere and volt meters are available, and also if the owners of the plants possess suitable rheostats? This card, when finished, should be of great service to the electromobile tourist in France, as it is not possible in all cases to obtain a supply from a public authority or electric lighting company, and many of the manufacturers possessing an installation for their work would no doubt be pleased to sell a small amount of their current at a reasonable rate.

Street Obstruction.—The laying of the Post Office telephones is proceeding, but it would hardly be right to say rapidly. The work of laying mains in London is not easy, but one might hope that in the streets of the City, where the traffic is very heavy, some effort would be made to hurry on the work and cause as little inconvenience as possible. This, however, does not appear to be the view of those responsible for laying these telephone lines, and the consequence is that all the busiest thoroughfares in the City are torn up, and work is proceeded with in a very leisurely fashion. We are informed, for instance, that there is no night work done, such as there should be in a place where a great number of vehicles are continually passing. The city engineer recently reported to the Court of Common Council that he had endeavoured, without success, to make the Post Office employ men on night work, and thus hurry on the operations. The Common Council have therefore again appealed to the Post Office on the matter, and we learn that the matter is now under consideration. While this is so, we suppose that workers in the City are to lose their time and suffer great inconvenience.

The Coal Strike in the States.—It will be remembered that at the time of the lamentable coal strike among the Welsh miners there was, in consequence, a large number of prosecutions in London on account of the smoke nuisance. We now note from the columns of the *Electrical Review* of New York that that city has experienced the same inconvenience in consequence of the coal strike in the States. Our contemporary's remarks on the subject are as follows: "Even to the casual observer it was evident that a coal strike was in progress last week, when the formerly smokeless city of New York became covered with dense clouds of black smoke, shot upward from a thousand chimneys that have done their work unnoticed for years past. New York has enjoyed a practically smokeless atmosphere for several years, and when it is considered that it is the largest manufacturing city in the United States, and that the enormous total of steam power developed in it requires the daily consumption of vast quantities of coal, it will readily be understood what a difference is made when pitchy and smoky bituminous coal is substituted for the almost smokeless fuel that has been lately in use. At this writing the prospects for the immediate ending of the strike seem excellent, and if for no other reason than that we desire to see the sun again, and emerge from the murky atmosphere of the last few days, this consummation is one that we all devoutly wish for." We see no note, however, to the effect that the various industrial undertakings in the city of New York are being persecuted because they are not able at once to make their chimneys smokeless, in spite of the fact that coal such as the furnaces were designed to burn cannot be obtained.

Jointing.—A patent has recently been granted to Mr. W. F. Barber, of Wilkesbane, U.S.A., for a metallic cement, which, he claims, acts as a solder, and does not require heating. Thus the wires are twisted, or mechanically secured together, and the cement is then applied. The cement consists of an amalgam, with a little binding material added, the mass having about the consistency of putty. When in mass the cement does not harden except at the surface, where a thin crust is formed. When worked between the fingers the mass becomes soft, and can then be applied to the wires. The amalgam is stated to consist of four parts of zinc, two of tin, two of copper, two of cadmium, four of bismuth, two of lead, one of antimony, and eight of mercury. The solid metals are granulated and melted together, after which the mercury is added, the mass being stirred at the same time. When cool the mass is pulverised in a mortar, and a binding material, consisting of liquid glucose and silicate of soda, is thoroughly mixed with the metals. The cement thus formed when in bulk will not harden, and may easily be worked between the fingers, but when spread out upon a joint it not only adheres to it, but hardens in from 12 to 24 hours. The cement may be applied to the wires without any previous application of acid, and by amalgamating with the conductors it forms as perfect an electrical union as could be formed by the application of solder without the inconvenience attending the application of the latter. The application of the cement prevents oxidation of the wires. The above details must be amplified by others concerning the resistance and endurance of the joints made before any valuable opinion can be formed of the method.

Wanted Electrical Comforts.—That electricity could be used to a very much larger extent than at present for the comfort of human beings will not be denied. Mr. R. S. Hale, in commenting on this fact in the *Electrical World*, mentions a few of the ways in which he would increase his comfort by the use of electricity. In the first instance he refers to the lighting of a house, and advocates a system of three-point wiring, in which the lights can be turned on or off from various places as may be convenient. This system, though apparently little used in America, is very common in England, many large houses and other buildings being fitted in this way. The author also mentions the lighting of the stairs on one floor of a building only, switching on or off at the bottom or top of each staircase. For bedroom lighting he states he has a switch at the door by which he turns

Digitized by Google

on the lights before entering the room, and also another switch close to the bed by which he can turn the lights on or off as occasion requires without getting up to do so. Another arrangement which finds favour in his eyes is an electric bed warmer, by means of which and the help of a pendant switch he warms his bed when he feels cold. For stair-lighting he recommends the use of push switches, it being easier with these for a servant to switch stair-lights on and off when carrying a tray or other article. The author thinks an electric lamp should be placed in every cupboard and wardrobe, by which means the dropping of grease from a candle on to the clothes may be avoided. The extra cost of the fittings of which he speaks would, he states, not add 25 per cent. to the cost of wiring a house, and would add 10 per cent. to the comfort.

Bacterial Light.—Speaking of the uses which are now being found for various micro-organisms, the *Lancet* mentions as a thing to be cultivated that kind of bacteria which emits a phosphorescent light. The phosphorescent microbe, it states, if properly fed, will grow and multiply enormously, emitting during its development a strange phosphorescent light. In the past this light has been looked upon as indicating phosphorus in the neighbourhood, but in a large number of cases it is not due to any chemical change, but to countless micro-organisms. In the case of the phosphorescence of the sea this is so, and in this case the phosphorescence is best when the sea is disturbed and the maximum of light is emitted from the crest of a short rapid wave, or in the foam produced by the water striking the shore. The light in this instance may be intensified by the addition of a combustible foodstuff, such as sugar, the light being caused by the oxidation of the bacteria, and if oxygen be excluded the light is at once quenched. The glow seen upon stale sea fish is said to be also due to these organisms and not to phosphorus, and it is possible to cultivate the phosphorescent bacteria so as to obtain a strongly phosphorescent fluid. This may be done by placing the flesh of fresh haddocks or herrings in a 2 to 3 per cent. solution of common salt and keeping it at a low temperature, say 7deg. above freezing, and it will then be found in a few days that not only the fish but the liquid give off a pale greenish light, which becomes more brilliant if sugar be added. The *Lancet* says, however, that it is not possible to say whether the culture can ever be carried to such a pitch that the vessel containing it can be used as a street lamp or as a Chinese lantern at garden parties.

The Strike on the Ashton Tramway.—With respect to the strike of tramway employés which recently took place on the Oldham, Ashton, and Hyde Electric Tramways the directors have issued a statement to the effect that, owing to the falling off in traffic following the conclusion of the fairs which are held in the district on Sept. 3, 12 motormen and conductors were given one week's notice to leave, but while working out their notice four of the 12 men were re-engaged to fill vacancies which had occurred during the week, so that on Sept. 10 eight men left the company's service. There is, it is stated, no truth whatever that the dismissal of the eight men was due to their being members of the union. With reference to the statement that the company dismiss men when they are in receipt of the maximum wage, the company point out that of the eight men two only were in receipt of the maximum wage, the remaining six being in receipt either of the minimum or intermediate wage. The present position is that 74 of the employés are on strike, 15 have remained with the company, and 61 new men have joined the service of the company, making a total staff at present of 76. For the service of cars the company are desirous of running during the ensuing month or two about 100 men are required, and the 24 vacancies are being gradually filled. In a letter which the chairman of the company has addressed to the local Press, it is clearly stated that the company has no wish whatever to interfere with the right of the men to join the union. The directors also are willing to reinstate the men now on strike to fill the vacancies in the order in which they apply, and have instructed the superintendent to give preference to the men of good character, and to reinstate them at the same rate of pay which they were receiving prior to the strike. The only point at issue is the number of men to be employed to do the work of the company, and of this the directors must, of course, be the sole judges.

A Closed-Conduit Traction System. — In the issue for Sept. 19 of the *Electrical Review* of New York we notice a description of a system, invented by Mr. L. M. Machan, for operating a closed conduit for electric tramways. The top of the conduit is made of iron, forming practically a third rail in the streets. This third rail is divided up into sections, which are successively energised by the car passing over them. The length of the section is about one-fourth that of the car. At intervals of 4ft. are placed contact-making receptacles, which consist of a porcelain cell containing an aluminium cup. The cup is partly filled with mercury, and in this is immersed the stem of a rivet-shaped contact-making device, which is adapted to be attracted upward against the under surface of the working conductor when the latter is magnetised. Attached to the car is a pair of electromagnets, hinged to which for convenience are the collectors. These magnets are energised by a storage battery of small size on the car. The magnetic effects produced by these two magnets on the third rail are expected to lift up the plungers described above, and it is claimed that the system is novel. We are surprised that the editor of our contemporary allows such a claim to appear in his columns. The system is a reproduction of one of the crudest systems of closed-conduit working, and we make bold to say that the inventor has not tried it on a large scale with apparatus made as illustrated in our contemporary. The eddy currents produced in the body of the third rail, if sufficient lines of force are to go through it to attract the plunger, would be very great indeed; and although the magnets might be energised with a small storage battery, they would give rise to a very great waste of power in this way. In fact, we doubt if with high speeds it would be possible to work at all as proposed. Unfortunately, in these days it is so much easier to write a description for a technical paper than to carry out the practical work necessary to prove the truth of what is written. In this case, however, the system can be rejected on theoretical grounds.

New Incandescent Lamp. — A new process of manufacturing incandescent lamps is now in operation in the Paris Exhibition. The process consists in producing the vacuum by the absorption of the gases by certain chemical substances which have been previously introduced into it. In this Malignani process, as it is called, a partial vacuum is first obtained in the bulbs by an air-pump; to absorb the remaining gases red phosphorus is stated by the *Scientific American* to be the compound generally used, and it is formed into a somewhat liquid paste, which is introduced by means of a piece of cotton on the end of a wire into the tube by which the bulb is exhausted, and the walls of the tube are coated with the paste. A vacuum is first made by the air-pump, and it is found that at a low pressure many of the gases will be absorbed by the compound used, especially oxygen, hydrogen, nitrogen, and the

Digitized by Google

hydrocarbon gases; the latter are most easily absorbed, and are in consequence used in practice. After the partial vacuum has been reached, the hydrocarbon gases are introduced into the bulb to displace the air; the pump is operated for half a minute while a current is sent into the filament, which brings it to dull redness. When the vacuum is made as nearly complete as possible by the air-pump, a stronger current is passed through the filament, and the outside of the bulb heated by a small gas furnace placed below it. When the vacuum has reached a certain point, a light-blue discharge appears at the positive pole, which increases, and eventually fills nearly the whole of the bulb; at this point the lamp is separated from the pump by melting off and closing the tube. The chemical product on the walls of the tube is then heated, and it absorbs the remaining portion of the gases; at this point the discharge appears to fill the whole of the lamp, having a light-blue appearance. Upon heating the lamp for a few moments, the discharge disappears, and the vacuum is complete. The glass tube is then removed from the bulb by melting off in a blow-pipe flame. The advantages claimed for this lamp are that the vacuum is better, the operation is more rapid, and it does away with the inconvenience of using mercury pumps.

Institution of Electrical Engineers.—We have received the list of meetings of the Institution which are to take place during the coming session. The opening meeting is fixed for Thursday, Nov. 8, at 8 p m., when the premiums for papers read in 1899-1900 awarded will be presented, and the president, Prof. J. Perry, M.E, D.Sc., F.R.S., will deliver his inaugural address. As usual, there are two meetings set down for each month, the last being on the annual general meeting, which is to be held on May 23. The total number of meetings set down on the list is 14. We have also received a card giving the arrangements for the meetings of the local sections. These sections are formed, as announced last session, at Birmingham, Dublin, Glasgow, Manchester, and Newcastle-on-Tyne. Of these, the Birmingham section has not yet been properly constituted, and in consequence the arrangements have not yet been settled. At Dublin, however, the session will open on Nov. 22, and a meeting will be held each month at the rooms of the Royal Dublin Society. The hon. secretary for this section is Mr. F. Gill, Telephone-buildings, Dublin. At Glasgow, where considerable progress was made in the past session, Mr. E. G. Tidd acts as hon. secretary, his offices being at 25, Gordon-street, Glasgow. Here, again, seven meetings, beginning on Nov. 14, will be held, the rooms of the Institution of Engineers and Shipbuilders at 207, Bath-street, Glasgow, being used for the purpose. The Manchester section will hold two meetings each in November, February, and March, and one meeting each in December, January, April, and May, the opening meeting taking place on Nov. 13. The place of meeting will be the Owens College, Manchester, Mr. E. W. Cowan, Springfield-lane, Salford, acting as hon. secretary. At Newcastle the session begins on Nov. 12, but finishes on March 25. There are, however, between these dates to be 11 meetings. Mr. J. F. C. Snell, of the Sunderland Corporation electricity works, has consented to act as hon. secretary, and the section is to meet at the College of Science, Newcastle-on-Tyne, if possible. A footnote on the card informs us that the dates are subject to alteration, if necessary.

Railway Power Transmission.—On Sept. 18 Mr. A. H. Armstrong read a paper before the Street Railway Association of the City of New York on the above subject, in which some useful conclusions are drawn as to the advantages of the various systems of distributing power for railway work. The available systems he classes as five in number. The first of these is the ordinary 500-volt direct-current supply. The next system employs series-wound direct-current boosters in the feeders from a 500-volt station. The third system is a three-wire one, using the track as neutral. The fourth is an alternate-current distribution, with sub-stations containing step-down transformers or rotary converters. The last system mentioned by the author employs alternate-current induction motors on the cars with the same system of distribution, with the exception that the rotary converters can be dispensed with. For tramway undertakings covering comparatively small areas the first two systems are undoubtedly the best. The author goes on to state that where larger systems of tramways are required, the local conditions must largely determine whether it is better to employ the direct-current supply with boosters or the alternate-current supply with sub-stations containing rotary converters. When, however, suburban roads have to be operated with great lengths of track, heavy cars, and high speeds, it will be found that the alternate-current supply with sub-stations and rotary converters is more economical than to build a number of small direct-current stations at various parts of the roads. When, on the other hand, the existing steam railways for suburban work and trunk lines have to be supplied, with a comparatively unfrequent service of heavy trains, the author considers that the induction motor has several advantages. For instance, it saves the large labour account which is caused by the running of machinery in sub-stations employing rotary converters, and it provides by means of the induction motors a fixed speed to trains independent of grade and line voltage. When, even with these trunk lines, the service becomes more frequent, he considers that it may still be advantageous to reconvert into direct current. The final conclusion of the whole matter is that no hard-and-fast rule can be made, but that each system must be considered on its own merits.

International Association of Municipal Electricians. — At the fifth annual convention of this association, held in Pittsburgh, U.S.A, from Sept. 25 to 28, Mr. J. L. Morgan, formerly city electrician of Kansas, read a humorous communication, in which, according to the *American Electrician*, he said he was no longer an active member of the association, as the office of city electrician had been abolished some six months before. Referring to some of the conditions under which the city electrician labours, Mr. Morgan said that "his employers consist chiefly of the mayor and a city council, or probably the city council and a mayor. Characteristic curves of the mayor may be more or less easily plotted, but no one can foretell the vagaries of the city council." The ethics of the profession, he continued, demand that dignity should be omnipresent, but dignity and aldermen are strangers. "In vain you attempt to discuss with an alderman plans which you have for bettering the electrical condition of the city, or money that you have saved by the elimination of electrolytic electrolysis. The alderman dismisses such a proposition with a gesture, and brings you down to earth with a jar by telling you that he has a friend whose door bell doesn't work, or that his electric light meter is working overtime. If he doesn't want a door bell fixed or a meter shunted, he probably wants a city telephone placed in his hall, or a city arc lamp in his parlour, or perhaps he only wants his gasolene stove repaired. When the influential member introduces you to his brother-in-law, and confides to you that he is to be your chief or sole assistant, that he is a first-class Kalsominer,

Digitized by Google

and in a few days will learn to be a good electrician, you must cheerfully accept this as an axiomatic proposition; never show the slightest annoyance; if you don't like him, take him out and connect him up with the alternating-current primaries. This is not crime, but philanthropy. Endorse unreservedly any and every proposition advanced by any member at any time or at any place. It is also wise to express an eagerness to personally assault any person, not a councilman, who has the slightest views opposed to those of the aforesaid member." Speaking in a more serious vein, Mr. Morgan advocated State control as a remedy for the more or less grotesque conditions pertaining to municipal systems, contemplating the appointment of a chief electrician who would have deputies to supervise the work, not only in large towns, but in small ones as well. This arrangement, he pointed out, would also remedy the existing defect that small cities and towns have practically no expert protection.

The Pan-American Exhibition.—Our American contemporaries, in most of their recent issues, have something to say respecting the Pan-American exposition, the buildings for which are now in a well forward state of construction. The electricity building is 500ft. long and 150ft. wide, but has an exhibition space of only 25,000 square feet owing to architectural work. In the north-west corner is to be placed a 5,000-h.p. transformer plant, consisting of 19 250-kw. General Electric air-blast transformers, which will transform the Niagara Falls Company's polyphase current at 11,000 volts down to 1,800 volts for distribution. Other step-down transformers will also be used in the buildings. In addition to the 5,000 h.p. from the Niagara Falls Company, an auxiliary power-house is to be located in the grounds for lighting the large number of arc lamps with which the exposition will be lighted Prof. G. F. Sever, who is superintending the electrical exhibits, has issued an announcement setting forth that electricity is to be used in lighting the grounds and buildings of the exhibition, it being the most convenient and adaptable system of lighting. He states that probably all the buildings will be outlined in incandescent lamps, and also the electric tower, which will be a central figure. There are also to be many novel and interesting electric fountains, and displays with combined water and electric effects. In order to carry out the suggested schemes over 200,000 incandescent lamps are to be utilised, and in order to get the best effects arc lights will be confined exclusively to the borders of the grounds. The illumination of the aisles and interiors of the buildings is, however, to be done by arc lamps. The electrical and mechanical buildings are to be placed close together, in order that clear comparisons may be made. It is proposed to make the electrical section of this exposition unique. Previously, electrical exhibits at expositions have been largely confined to large spaces filled by individual exhibitors, so as to demonstrate the amplitude of their resources, but for the Pan-American exposition each manufacturer is invited to contribute only such articles as may be considered really novel or of interest, thus making the exhibit a collective one, rather than one exclusively composed of individual commercial exhibits. Another important factor which has necessitated a selective exposition in this particular instance, is the small amount of exhibition space as compared with the area occupied by the buildings. The exhibits will therefore be divided into two groups—the collective exhibit, which will consist of retrospective exhibits of historical interest, illustrative models or practical contrasts showing the advances in the art; and the commercial exhibit, which will be composed of those exhibits possessing distinctive merit, whether this consists in workmanship, novelty, or useful applications. The exhibits are to be classified into 12 different sections, and it is intended to place commercial and operative exhibits together in one part of the building, the historical exhibits and models being in another portion. The cost for floor-space in the building is to be from 4s. 2d. to 6s. 3d. per square feet.

Institution of Civil Engineers.—The eighty-second session of this institution will open on Nov. 6, at 8 p.m., when the president, Mr. Jas. Mansergh, will deliver his inaugural address and distribute awards for papers read in the past session. Mr. J. H. T. Tudsbery, the secretary of the institution, has sent us a list of subjects upon which papers are invited, and also a copy of the rules for the admission of students. There are some 83 subjects set forth upon which original papers are invited, and amongst these we notice in the railway section: the increase of speed in express travelling; the application of machinery in large railway goods yards and sheds and street railways, having reference to different systems of traction—viz., steam, cable conduit, electric trolley, electric rail contact, electric conduit, and electric storage battery. In the machinery section papers are invited on: turbines; the most suitable steam-power equipments and the size of units for electric light stations; the theory and development of the compound steam-turbine; methods of testing the lubricating values of oils, grease, etc.; and methods of removing moisture from steam, and of reducing losses by radiation from steam-pipes. In mining and metallurgy papers are asked for on: mechanical appliances for coal getting; the manufacture and use of steel for electromagnetic purposes; and the extraction of metals from their ores by electrolytic processes. There are 10 suggestions put forth as to electrical subjects, these being: the use of electric energy in working mines; the utilisation of electric energy for heating purposes; the application of electricity to traction on roads and tramways; the first cost and economy of operation of electric traction on railways with heavy trains; the utilisation of electric lighting plant during hours of small demand; the use of electric motors for driving machines in textile factories and in engineering workshops; the use of electrical machinery for lighting and for the transmission of power in warships and in the mercantile marine; the regulation of electric pressure in large lighting circuits as carried out at the engine, the dynamo, or the exciter; the progress of telegraphy and telephony at home and abroad; the electrolytic action of return currents in electrical tramways on gas and water mains, and the best means of providing against electrical disturbances. Amongst the premiums which the institution awards for papers read at the institution, the first is the Telford Fund, which produces £235 annually, and is expended in annual premiums under the direction of the council. The Manby Donation is also given for an annual premium for papers read. The Miller Fund provides for a scholarship, which is awarded each year, and is tenable for three years, the scholarship not exceeding £40 in value. The Howard Bequest provides for a prize or medal, which is presented once in five years, for a paper on "The Uses or Properties of Iron," or for some new and valuable process relating thereto. The Crampton Bequest provides a prize or medal for the author of the best paper on "The Construction, Ventilation, and Working of Tunnels of Considerable Length." The James Forrest Medal is annually presented to the student contributing the best paper in that class. The James Prescott Joule Medal is given every third year to a student for the best paper presented on an engineering subject, preference being given to one dealing with the transformation of energy.

LIVERPOOL ELECTRIC LIGHTING.

Mr. A. Bromley Holmes was born at Derby, June 8, 1849, and educated at Repton School, near Burton-on-Trent. In 1868 he commenced pupilage under Mr. A. Buchanan, of Messrs. Andrew Handyside and Co., engineers, at Derby, and was subsequently for seven years in the employment of that firm. In 1881 he commenced business as consulting engineer in Liverpool in partnership with Mr. J. C. Vaudrey, and was managing engineer for the Liverpool Electric Supply Company, Limited, from its formation in the year 1883 till its purchase by the Corporation of Liverpool in 1896. On July 1, 1896, he was appointed city electrical engineer by the Corporation of Liverpool. Mr. Holmes was elected a member of the Institution of Civil Engineers in 1888, and is a member of the Institution of Electrical Engineers.

Through the courtesy of Mr. A. Bromley Holmes, the city electrical engineer of Liverpool, we are able to give a few particulars of the new electric light stations which have recently been put to work in that city. It was on his advice in 1898 that the Corporation determined to provide amply for the rapidly increasing demand for electrical energy. This demand even as far as electric lighting only is concerned has increased in a remarkable way in Liverpool, but the introduction of electric traction for the tramways has given a still further demand, which only prompt forethought could have enabled the Corporation electrical department to meet. It was accordingly decided to build two new large power stations. In Fig. 1 we give a general map of Liverpool, in which the positions of these two stations can be seen. The one is at Lister Drive, and the other at Pumpfields, in Vauxhall-road, which is nearer the docks. As will be seen by the scale, the actual distance between these two stations is about 2½ miles, and the heart of Liverpool is between the two. The Pumpfield station, in which the photographs given below were taken, is built on the Leeds and Liverpool Canal; the other station, at Lister Drive, adjoins the London and North-Western Railway. The architecture of the two stations is practically the same, as is also the arrangement of the various departments. This arrangement is shown in Fig. 2, and in section in Fig. 3. These two illustrations were prepared from the actual drawing used for the Lister Drive station, in which the coal is obtained by railway instead of by water. These buildings were designed by Mr. Thomas Shelmerdine, the Liverpool Corporation surveyor, and the buildings were erected by Messrs. Morrison and Sons, of Liverpool. It will be seen that the arrangement of the station is such that the plant is divided up into four sections, each of which can be worked quite independently of the others. Each of these sections contains seven boilers, with an economiser in the main flue which leads to the chimney, and three steam dynamos with their accessories. The size of these steam dynamos is practically 800 kw., so that the ultimate output of each station will be, without spares, 9,600 kw. The engine-rooms in each station are made some 247ft. long and 50ft. wide, while the boiler-rooms at either side of the engine-room are 53ft. wide. The external appearance of these buildings can be seen from Fig. 4, which is the front elevation of the Pumpfield station, while Fig. 5 shows the back elevation of the same works. In this last illustration the arrangement adopted for getting coal into the works can be seen. This consists of an horizontal canvas belt near the canal, which is seen in the foreground, which delivers the fuel on to an inclined conveyor belt, which delivers it into the bunkers over the mechanical stokers. The space between the canal and the station can be used for storing fuel, but the bunkers and coal stores over the boilers hold a very large supply.

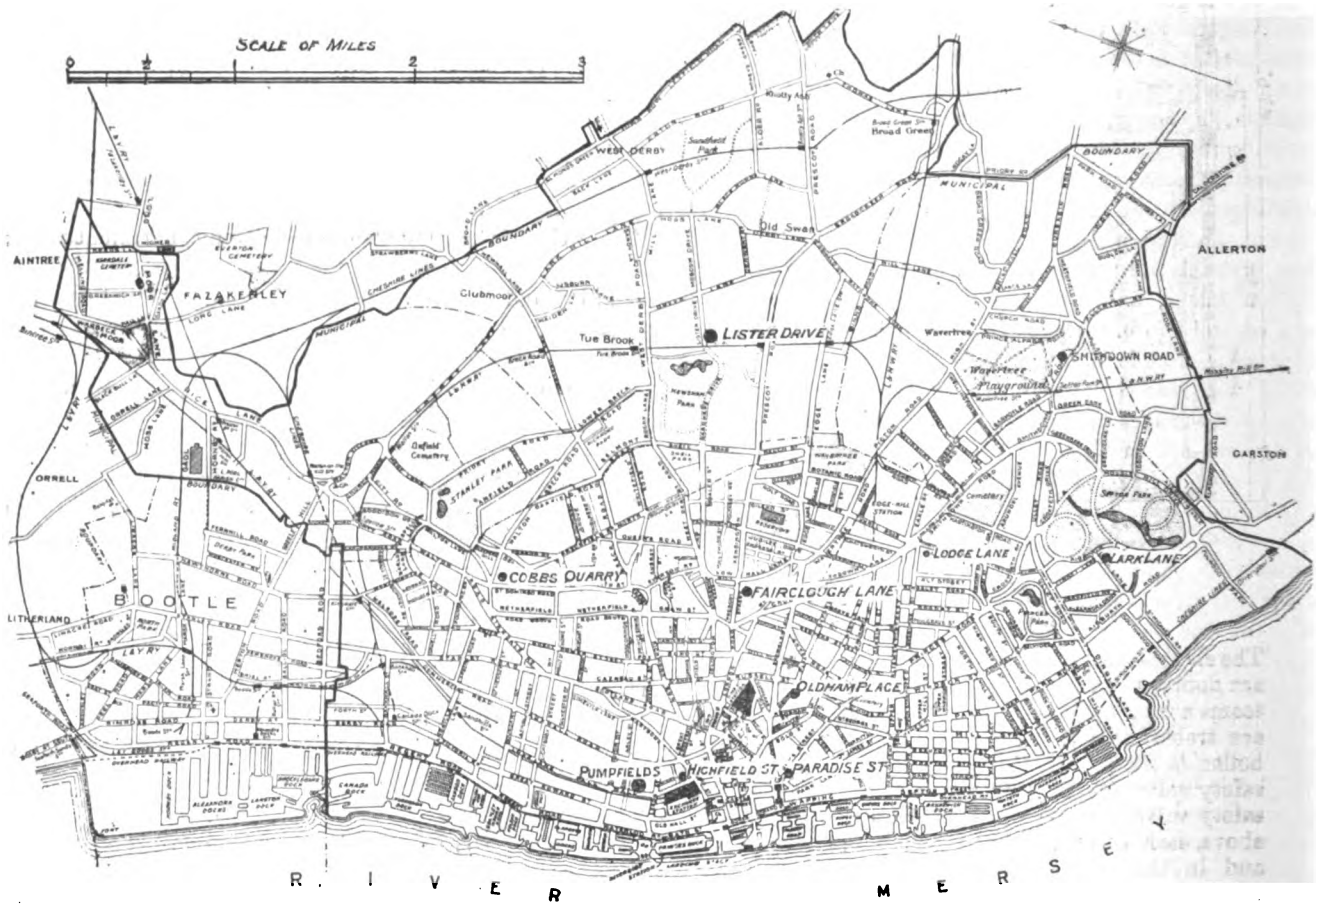

FIG. 1.—Map of Liverpool, showing the positions of the Electric Supply Stations of the Corporation.

Digitized by Google

At the Lister Drive station a railway siding is provided on each side of the works, from which the coal can be delivered into the wrought-iron storage chambers over the mechanical stokers. The arrangement at this station can be seen in Fig. 3. The ashes from the mechanical stokers are also raised by elevators on to a platform, from which they can be delivered either into railway trucks or into carts for removal. The mechanical stokers in use at these works can be seen in Fig. 6. These stokers are of the Vicars type, and it will be noticed that the hoppers are well cased in, so that the stokehole should be easily kept clean and free from dust. The stokers, elevators, and conveyors, as well as the scrapers of the economisers, are driven by motors.

The boilers at the Pumpfield station were supplied by Messrs. Tetlow Bros., of Hollinwood, and at Lister Drive by Messrs. Galloways, Limited, of Manchester. They are of the Lancashire type, 30ft. long and 8ft. diameter, flues 3ft. 2in. diameter, each fitted with five Galloway tubes.

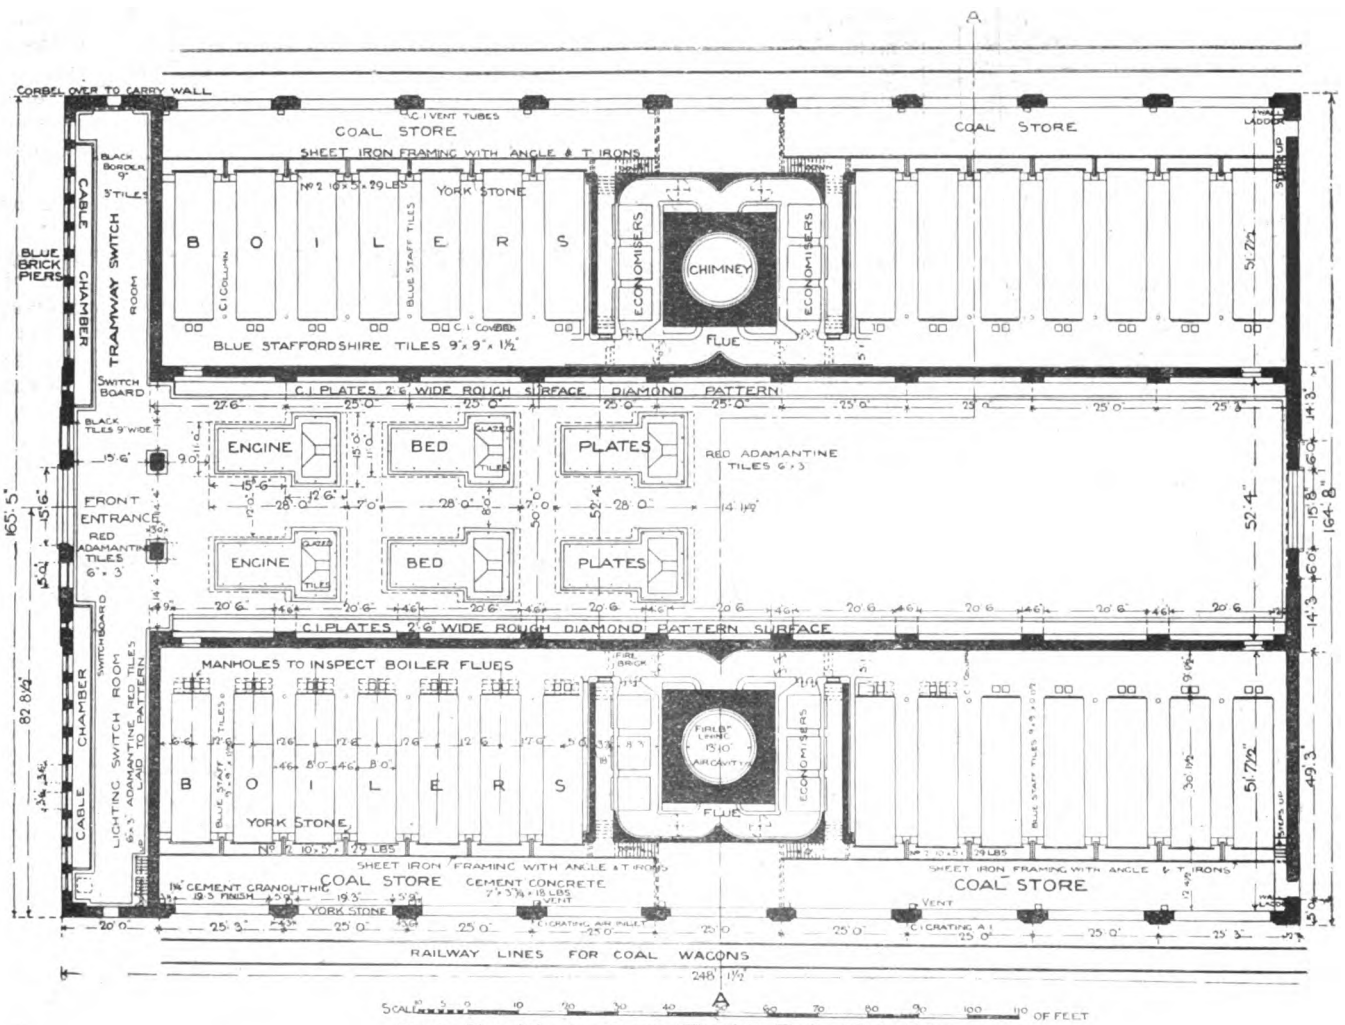

FIG. 2.—Plan of the New Liverpool Electricity Works at Lister Drive.

The shell plates are of steel, ¾in. thick. The circular seams are double riveted with lapped joints, and the longitudinal seams are butt-jointed with straps inside and outside, and are treble riveted. The flue plates are ½in. thick. Each boiler is fitted with 8in. parallel slide steam stop-valve, a safety valve for high steam and low water, and a duplex safety valve, and the other usual fittings. As mentioned above, each section of seven boilers is worked independently, and in the flue from each section is placed a Green's economiser. Each of the boilers is fitted with an injector for injecting the feed water into the boiler, and a duplicate supply is obtained from a vertical direct-acting steam feed pump.

Up to the present the engines used are all of the Willans and Robinson type, designed to run at the speed of 230 revolutions per minute, with an output of 1,200 i.h.p. on continuous load and 1,500 i.h.p. for short periods. The engines are single acting, having three cranks, the crank-shaft being 11in. diameter. The cylinders are 15in., 20½in., and 34⅝in. diameter, and the length of stroke 16⅞in. The bearings are lined with white metal. The engines are fitted with a high-speed sensitive governor and speed regulating gear, and also with automatic expansion gear. The armature of the dynamo forms the flywheel. These engines, with their dynamos attached, can be seen in Fig. 7, which gives a very good idea of the neatness of the station.

The dynamos are of the Siemens multipolar type, having an output of 1,420 amperes at 550 volts. The field magnets are mounted on a steel ring, made in halves and strongly bolted together, carrying 10 steel bolts. The magnets are shunt wound. The armature winding consists of copper bars, individually insulated and securely fixed in slots formed in the armature core, which is built up of best charcoal iron securely fixed to the steel centre of the armature. The commutators being of large diameter, special care has had to be taken in their mechanical construction in order to provide for the great centrifugal force which occurs at the comparatively high speed at which they are run. For this purpose steel enters very largely into the construction. The brush gear is of most substantial design, and is worked by a worm and wheel adjusting arrangement. As is usually the arrangement with such machines, the brushes are of carbon. The leads connecting the alternating sets of brushes are contained in the hollow casting which forms the support for the brush gear.

Both the two stations are working condensing. At the Pumpfields station the Korting ejector condensers are employed, and the condensing water is raised from the canal by Allen's steam-driven centrifugal pumps to overhead tanks. The water flows from the condensers by gravity in pipes along Vauxhall-road to a branch of the canal adjacent to Leeds-street, between which point and the station a large cooling area is provided. At Lister Drive the condensing is effected by a Klein counter-current jet condenser and steam-driven air and circulating pumps. The condensing water is cooled by means of two Klein's patent chimney coolers. The condenser is fitted with an automatic exhaust relief and oil separator.

Digitized by Google

Each station is provided with an accumulator room, with accommodation for four batteries of 240 cells each, each battery being capable of giving a discharge of 200 amperes for one hour, or 80 amperes for four hours. The accumulators are used to equalise the load for the tramway service, and to assist in balancing the load on the two sides of the three-wire supply for the lighting service. Balancers are also provided at each station for equalising the load

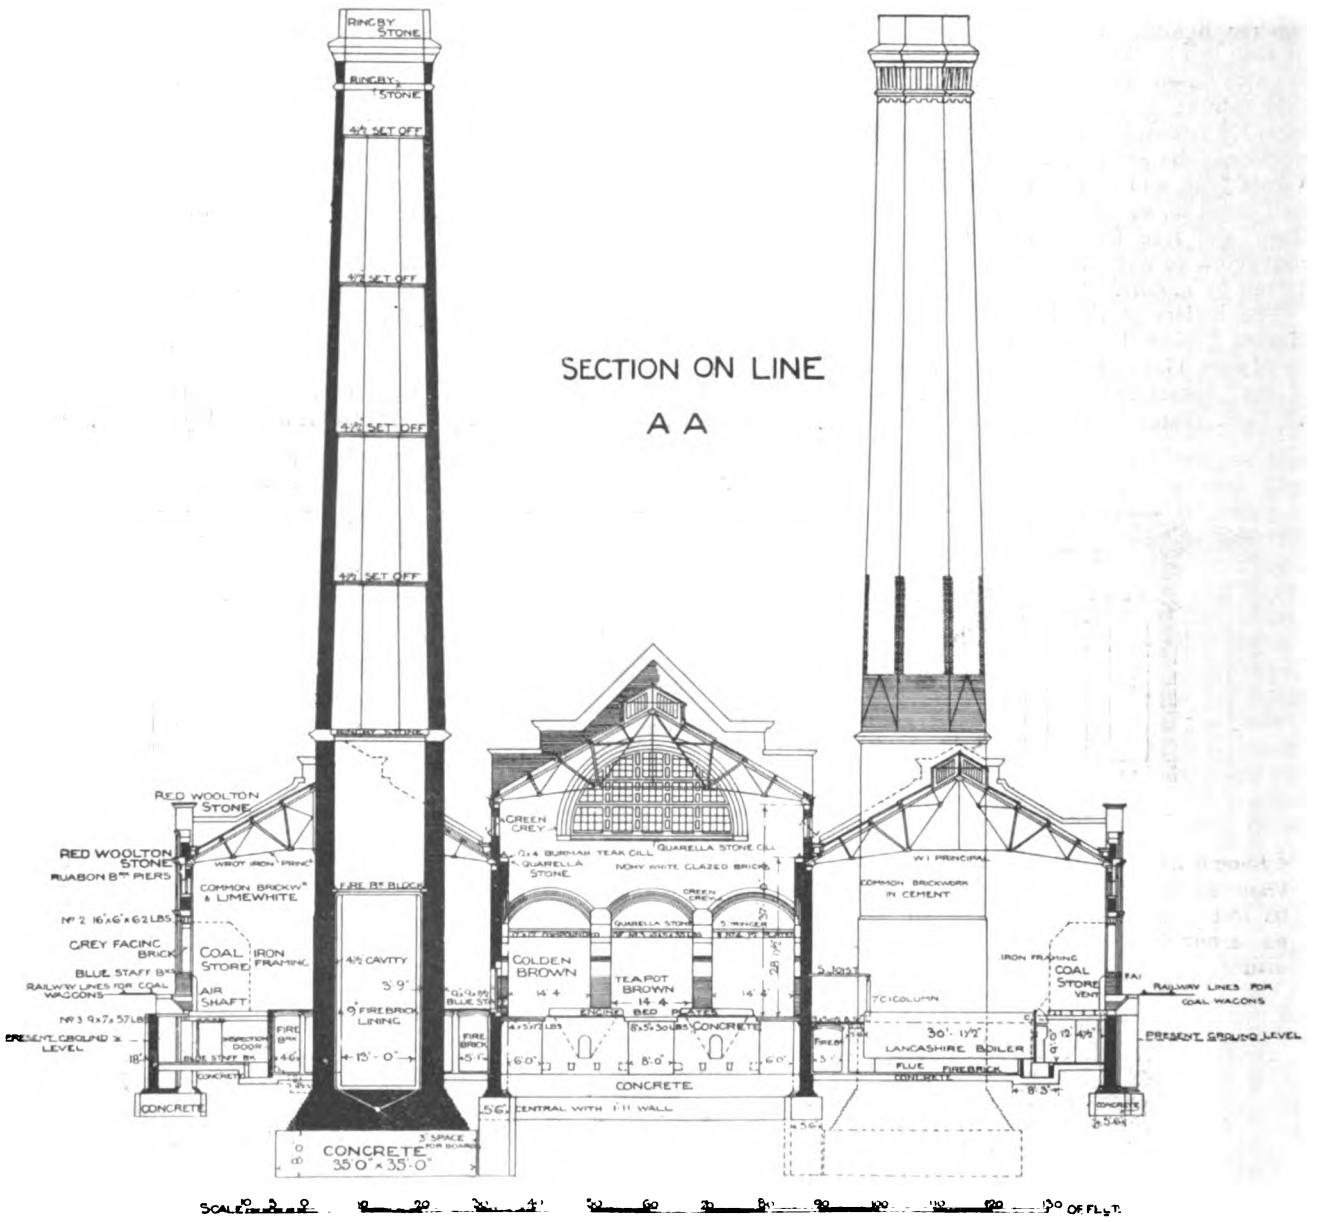

FIG 3.—Sectional Elevation.

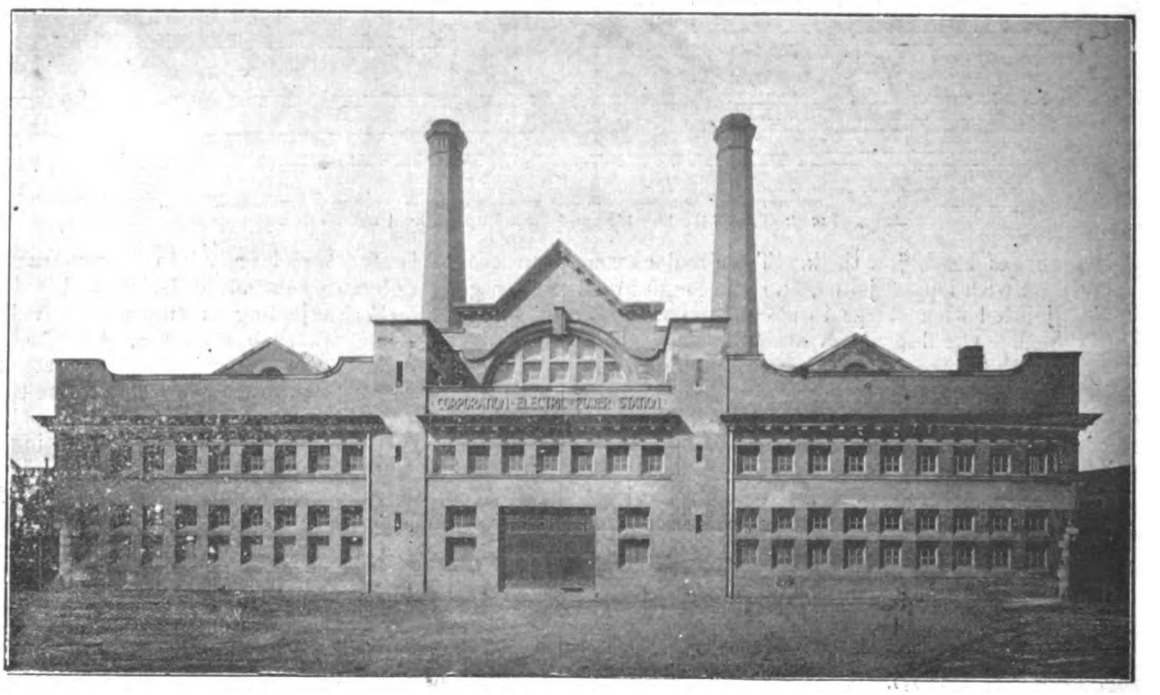

FIG 4.—Front Elevation of Pumpfields Electricity Station of the Corporation of Liverpool.

Digitized by Google

on the three-wire lighting mains, and motor-generators are also provided for the charging of the accumulators.

At each station there are two switchboards (Fig. 8), one for the lighting service and one for the tramways. The dynamos on one side of the station are connected to the tramway switchboard, and on the other side of the station to the lighting switchboard. The two switchboards are so connected that any set of plant may be used either for the lighting or for the tramway service. By this means it is possible to work the plant in the station in such a way that each set may run the same number of hours annually. The distribution of electrical energy for the tramways is at 500 volts pressure, with an earth return, and the distribution for lighting and power is on the three-wire system of 460 volts between the outer conductors, the middle wire being earthed at the station.

The following figures are of interest as showing what an important undertaking the electric lighting of Liverpool now is. Thus at the present time there are the equivalent of 132,000 lamps of 16 c.p. connected to the supply mains of the Corporation, and more than 150 electric cars are in daily service on the tramways. The number of units supplied during the half-year ending June 30, 1900, was: for tramways, 2,197,937; for lighting and power, 2,243,225—total, 4,441,162.

In addition to the two large stations described above, electrical energy is distributed in the central portion of the city from the Oldham-place, Highfield-street, and Paradise-

The residential district of Sefton Park and Princes Park derives its supply from the Lark-lane station, which, with

Digitized by Google

the three town stations referred to above, were purchased by the Corporation from the Liverpool Electric Supply Company, Limited, in the year 1896.

The revenue of the electricity department of the Corporation of Liverpool last year exceeded £73,000, in spite of the fact that the electric tramways were not nearly completed. This year a higher return, both for lighting and traction, is to be expected. We have to express our thanks to Mr. A. Bromley Holmes for the photographs and drawings from which our description of the new stations were prepared. At the same time, we would congratulate the people of Liverpool on these new works, and on the economical production of electrical energy which will result from Mr. Holmes's careful designs.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

EIGHTH ANNUAL MEETING AT KIEL.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 269.)

Another and undoubtedly one of the most useful papers contributed to the proceedings of the Verband at Kiel was that by Mr. Gisbert Kapp, which described an instrument for measuring the tractive effort required for motorcars on electric railways. The following is an abstract of the paper:

In the car to be equipped a tube is mounted parallel to the track, the ends of this tube opening up into vertical limbs. Let us assume the track to be perfectly level and the tube filled with water up to a point marked upon one of the limbs, which we will call the zero point. In order that the level of the water may be observed, this limb consists of a glass tube. If the main tube be inclined, the level of the water will change in proportion to the tangent of the angle of inclination, and we may thus conceive a scale marked upon the vertical glass tube with the zero point as its centre, the divisions of which correspond to the gradients 1 : 1,000, 2 : 1,000, and so on. The spacing of the division marks will depend upon the internal diameters of the vertical limbs and the length of the horizontal tube. Now, assuming the car to be at rest on an incline, the instrument, as described, being so mounted that the tube lies parallel to the track, the water-level will indicate with sufficient accuracy the gravity component in the direction of motion in kilogrammes per tonne of rolling weight, or other unit selected. The reading will not be absolutely correct, because the change in the water-level is proportional to the tangent, while the gravity component is, on the other hand, proportional to the sine of the angle of incline. Even in the case of considerable gradients the error is, however, extremely small. For instance, with a gradient of 5 per cent., the difference between the tangent and sine amounts to $\frac{1}{750}$, or 0·13 per cent., and for the maximum gradients met with in tramway work—that is to say, about 10 per cent.—it is only $\frac{1}{185}$, or 0·54 per cent. of the recorded value. That portion of the tractive force required to overcome the gravity component may therefore be read on the graduated glass tube without difficulty when the car is ascending a uniform gradient at a constant speed.

Now let us consider the case with the car moving upon the level at a variable speed. The accelerating force acting upon the water in the horizontal tube, due to the acceleration of speed, causes a change of the water-level. If l be the length of the horizontal tube, and h the difference in height between the water-levels in the two limbs, then

$$l\frac{p}{g} = h,$$

p representing the acceleration imparted to the car, and g the acceleration of the gravity. As $\frac{p}{g}$ is always smaller than 1, we may put

$$\frac{p}{g} = \sin\beta,$$

where β represents the angle at which the stationary apparatus must be inclined in order to give the same deflection as that resulting from acceleration on the level track. Hence the tractive force required to accelerate the speed of the car may also be read on the scale, so that the water-level at once indicates the total force in kilogrammes per tonne of rolling weight requisite for the gradient and acceleration. The following investigation will serve to show the degree of accuracy with which these data may be obtained. In Fig. 1 let $a\,b$ represent the horizontal tube of the length l, $a\,c$ and $a\,d$ its two vertical limbs, α the angle of inclination of the track, and p the acceleration imparted to the tube parallel to the direction of its length.

Further, let B and F represent the water-levels in the two limbs. Of the total indicated difference of level

$$\mathrm{A\,F} = l\tan(\alpha+\beta),$$

$$\mathrm{A\,C} = l\tan\alpha,$$

represents that part due to the gradient, and

$$\mathrm{C\,F} = \frac{\mathrm{E\,F}}{\cos\alpha},$$

the part due to the acceleration, whence

$$\mathrm{E\,F} = l\sqrt{1+\tan^2(\alpha+\beta)}\,\sin\beta,$$

$$\mathrm{C\,F} = l\sqrt{\frac{1+\tan^2(\alpha+\beta)}{\cos^2\alpha}}\,\sin\beta.$$

Without falling into appreciable error, we may take these root values as our units. The tractive effort indicated

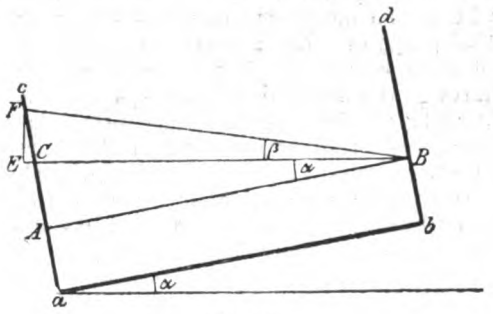

FIG. 1.

on the scale is A F kilogrammes per tonne; the actual value is

$$1{,}000\left(\sin\alpha+\frac{p}{g}\right)\text{ kg. per tonne.}$$

Hence by introducing an error factor into the calculation, which we will denote by $1{,}000f$, we obtain the equation

$$l\tan(\alpha+\beta) = 1{,}000f + 1{,}000\left(\sin\alpha+\frac{p}{g}\right).$$

As the relative dimensions of the instrument exert no influence upon the theory of its limit of error here investigated, we may give l what value we please. If we make the tube 1m. long, the scale divided into millimetre divisions will indicate the tractive effort in kilogrammes per tonne. The above equation now assumes the simpler form:

$$\tan(\alpha+\beta) = f+\sin\alpha+\frac{p}{g};$$

$$\tan(\alpha+\beta) = f+\sin\alpha+\sin\beta.$$

It is at once clear that the error will be the greater, the greater the gradient, and the greater the acceleration. As a mean value for the acceleration, we may take 0·4 for street tramways, while 0·75 may occasionally be reached, though, having regard to the comfort of the passengers, the latter figure would hardly be exceeded under ordinary circumstances. When the brakes are applied, especially if the emergency brake be used, this value may, however, be considerably exceeded. If the instrument is to be employed to determine the tractive effort of the motor, it would be well to take $p = 0{\cdot}75$ as the extreme limit of acceleration. But should it be desired to investigate the effect of the brake, we must assume a maximum retardation of about 1·40 upon the level in order to determine the maximum error.

Digitized by Google

For example, with a 5 per cent. grade and an acceleration of 0·4, we obtain

$$\sin \alpha = 0\,05;$$

$$\sin \beta = \frac{0{\cdot}4}{9\,81};$$

$$\sin \alpha + \sin \beta = {\cdot}0907.$$

Assuming the instrument to be free from error, it would indicate a difference of level amounting to 90 7mm. In reality, it shows a difference of 1,000 tan $(\alpha + \beta)$, which, calculated on the basis of the above assumed values, gives us about 91mm. The instrument, therefore, indicates about 0·3mm.—that is to say, one-third per cent. too much. In a similar manner we may determine the errors corresponding to other conditions of working, and so obtain the following table for starting up and braking the car:

TABLE OF THE LIMITS OF ERROR WHEN STARTING.

Profile of track.	Level.			Approximate rise.			Approximate fall.	
	—	—	...	5 %	10 %	...	5 %	10 %
Acceleration.....	0 4	0·75	...	0·75	0 4	...	0 75	0·4
Percentage of error..	0·00	0 29	...	0·60	0·82	..	0 23	0 38

TABLE OF THE LIMITS OF ERROR WHEN BRAKING.

Profile of track.	Level.			Approximate rise.			Approximate fall.	
	—	—	..	5 %	10 %	..	5 %	10 %
Retardation	0·75	1·4	...	0·75	1 4	...	0·75	0·4
Percentage of error...	0·29	1·03	..	0·23	0 80	...	0·60	0·8

In each case the error is either smaller or of the same magnitude as the personal error in reading such instruments, whence the instrument may be taken as correct for all practical purposes. But another and, indeed, a greater source of error consists in that in ascending a rise and when starting, the forward car springs are somewhat relieved, while the load on the rear springs is proportionately increased, the reverse order of things being the case when the car is on the descent or upon applying the brakes. In consequence of this circumstance, the tube is not supported parallel to the track, but given a slight inclination towards the same. The tilting effect is aggravated by a small wheel base, and also by an increase in the height of the centre of gravity of the car above the supporting points of the springs; further the uneven distribution of the load may produce such a tilt. These constitute sources of error which cannot be generally determined, but must be individually treated. After approximate calculations, I have come to the conclusion that these errors may amount to some per cents. of the value registered.

The instrument indicates directly only that amount of force required for the grades and for acceleration, and not the balance of power required to overcome the frictional resistance. In order to determine this balance, we first get the car up to speed, and then switch off the current and let it run over a level stretch of track, taking at the same time the reading of the water-level. This gives directly the retarding forces exerted by the lines, gearing, and motor friction. In order to eliminate the influence of a possible slight rise or fall in the track it is advisable to let the car run thus freely in both directions, always taking care to observe the water-level reading at the same spot. The mean of the readings is the so-called traction coefficient expressed in kilogrammes per tonne of the rolling weight. When this coefficient has been determined, it is necessary only to shift the scale of the instrument a corresponding amount in order to be able at once to read the total tractive force.

The form of instrument just described is eminently adapted for mounting permanently in a motorcar, and the tube, *a b*, may be as long as the body of the car permits, the vertical glass limb being placed in any convenient position on the end wall of the car. This vertical limb may also be provided with a float arranged in connection with an automatic recording instrument, whereby a permanent record of the tractive force may be kept. As in the case of the ordinary type of recording instrument, the paper band is carried by a drum, which by means of a ratchet and electromagnet is turned through a certain predetermined distance at every complete revolution of one of the driving wheels. In this manner a curve of the tractive force as a function of the track is obtained. The area of this curve represents the work done per ton of rolling weight. Instead of a glass water-gauge, a correspondingly graduated manometer may be employed to indicate the pressure. However, an instrument constructed as described, on account of the great length of the tube, *a b*, is not portable. In order to obtain a portable instrument I have resorted to the use of two fluids—namely, quicksilver, which serves to produce the difference of pressure in the point, *a b*, and water, to indicate this difference of pressure. A diagram of the instrument is shown in Fig. 2, where A and B are two cups of 40mm. diameter each, *l* the connecting tube of such length that the vertical centres of the cups are distant from each other 50cm., and *d* the water-gauge glass of 5mm. internal diameter. With these ratios the deflection corresponding to a gradient of ·1 per cent. is 4·7mm., and since we can read correctly to within 2mm. the determination of the tractive force with an accuracy within about 0 5 kg. per tonne of the rolling weight is possible. By lengthening the tube, *a b*, greater accuracy might be obtained, but at the cost of making the instrument too unwieldy. Moreover, it is quite unnecessary to strive for a greater degree of accuracy, since in the first place this is not required for practical purposes, and in the second it would be illusive owing to the sources of error occasioned by the tilting of the car.

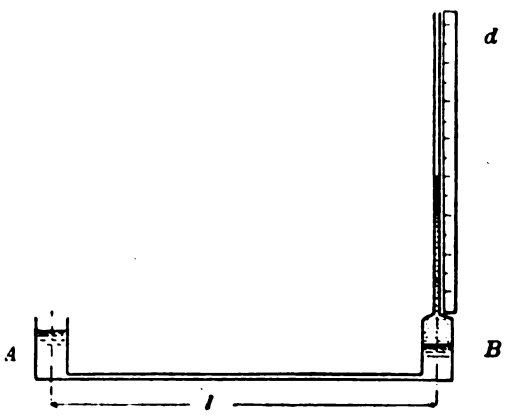

FIG. 2.

A much more convenient form of portable instrument could be constructed by substituting a coiled glass tube for the gauge glass. Since the gauge glass indicates only an angle of inclination, the same function might be performed also by means of the compression of the air in a uniformly bent tube. But although I have had constructed a half-dozen such tubes, I have not succeeded in obtaining with any one of them nearly the same accuracy of that given by the form shown in Fig. 2. This instrument has been subjected to tests both on one of the Berlin tramways and on the express railway owned by Messrs. Siemens and Halske in Lichterfelde. The damping obtained with the narrow tube, *l* (3mm. internal diameter), proved reliable for starting up and ordinary braking, but too great when it was a question of investigating the effects of the emergency brake. It is, therefore, advisable to give the tube a larger internal diameter, and to provide for adjustable damping by means of a throttle valve.

For the ordinary type of tramcar the instrument gave a traction coefficient of 12 kg. per tonne, which increased to 20 kg. round a moderately sharp curve. Upon the express railway the instrument was mounted in a car destined for the Berlin elevated railway, and indicated accelerating forces up to 75 kg. per tonne. Since the truck of the car is equipped with two bogies, and the centre of gravity lies somewhat low, a considerable tilting is avoided, and an error, therefore, scarcely to be expected. The free running trials to determine friction were made over a stretch of track having a gradient of ·3 per cent. During six journeys out and return (12 readings), with speeds of 13 5 km. to 30 7 km. per hour, the traction coefficient varied between the narrow limits, 8 kg. and 8·1 kg. per tonne. The weather was calm, whence it appears that air resistance has no appreciable influence for speeds up to 30 km. per hour. The increase of the coefficient produced by a curve of 200m. radius amounted to 1·5 kg. It remains to be added

Digitized by Google

that the car was quite new, not having been previously run, and after the trials it was discovered that a brake block had got heated, which would account for the somewhat high coefficient of 8 kg.

Contrary to what might, perhaps, have been anticipated, no discussion was evoked by this paper, though appreciation was evident.

(To be concluded.)

HIGH-SPEED RECIPROCATING ENGINES.*

BY ALLAN COATS, B.SC.

(Concluded from page 526.)

I do not suppose that the water in Messrs. Reavell's jacket is so great as this, but both Messrs. Willans and Mr. Raworth agree that steam-jackets are no use in high-speed engines. Another curious thing about these figures (Table A, Fig. 9) is that the combined efficiency rises as the engine is worked condensing. For instance, when the engine was working non-condensing and giving 47·8 h.p., the combined efficiency was 71 per cent.; while when working condensing and giving 43·6 h.p., so that the efficiency ought to have been (if anything) lower, the figure given is 77·8 per cent., or considerably higher.

TABLE A (Fig. 9).—Record of the Reavell Engine Test by Mr. Henry W. Gill.

Test No.	Steam press.	Vac.	Speed.	Output — Amps.	Volts.	KW.	Diagrams M.E.P. — L.P.	H.P.	I.H.P.	Steam per hour — Total.	Per I.H.P.	Per KW.	Combined efficiency.

The official test (non-condensing) was made in the presence of Mr. Oughterson. The engine was No. 30, and was tested on Jan. 26 and 29 last.

Governor Trial.

Load	0	¼	½	¾	Full.
Speed	414	412	410	408	408

Highest speed reached with full load thrown off, 420 revolutions.

The only case where combined efficiency can alter is when the load or speed is altered. The speeds in the trials do not vary at all, which, I think, can hardly be the case. The governor, however, is a very good one, although rather complicated: from full load to no load, giving 1·4 per cent. total variation, while the momentary variation gives 3·4 per cent. total variation. It governs on the principle of cutting off first and then throttling, from which the most economical results might be expected. This governor is, I think, the only throttling one which uses the effect of inertia as well as centrifugal force. The valve is kept single-acting by the pressure of the steam, and becomes double-acting at light loads.

Fig. 1 shows a new engine which I have designed and which was made by Messrs. A. F. Craig and Co., Paisley. Fig 10 gives the combined indicator diagram and Fig. 11 the various steam and inertia curves. Fig. 12 = turning moment at 567 revolutions.

The principal objection to single-acting engines is that they have a large cylinder volume per horse-power. This engine occupies a mid-position between ordinary single-acting and double-acting. For if we take the four spaces into which a tandem cycle engine is divided—*i.e.*, one above and one below each piston—three of them are used to expand steam in as against four in a double-acting and two in an ordinary single-acting compound. I do not say that this constitutes triple expansion, for the high-pressure shares the fall of temperature in the low-pressure, but the high-pressure does not reach the temperature of the low-pressure until the end of the return stroke, and not at the beginning, as most compounds do. There are other compound engines, like the Willans and Alley and McLellan, which divide the fall of temperature into three or even four stages, but their intermediate differences are very small—only 10lb. in the Willans compound as against 45lb. in this one. This engine has straight ports, which bell considerably at the mouth.

Turning to Fig. 1, steam is admitted to the underside of the high-pressure piston, and at ·6 of the stroke it is cut off and expanded. At the end of the up stroke, the high-pressure valve opens and places the underside of the high-pressure piston in communication with the upper side of the low-pressure. This valve remains open during the whole of the down stroke, so that steam in passing from the underside of the high-pressure to the top of the low-pressure is expanded again. On the following up stroke fresh steam is, of course, admitted to the underside of the high-pressure, while the low-pressure valve allows steam to pass from the top to the bottom of the low-pressure piston. At ·6 of the stroke the low-pressure valve is cut off, and the steam on the top side of the low-pressure piston is compressed, while that on the underside is expanded. The volume of the clearance on the top of the low-pressure piston is so arranged that at the end of the up stroke steam has been compressed up to the exhaust pressure from the high-pressure cylinder. On the second down stroke the steam is exhausted from the underside of the low-pressure piston, as usual. The top side of the high-pressure piston and the space between the high-pressure cylinder and valve chest is used as a steam

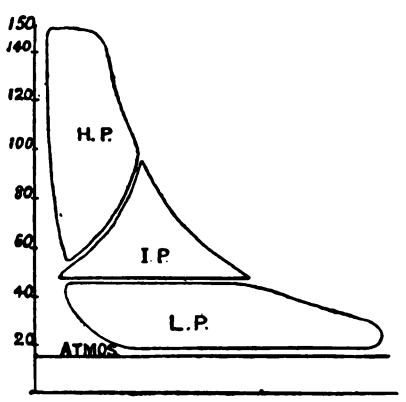

FIG. 10.

buffer. The supply of steam to this buffer is regulated by a small non-return reducing valve connected up to boiler steam. By regulating this valve, any pressure up to boiler pressure may be obtained at the bottom of the stroke in the buffer, and as it is a non-return valve, the pressure at top of stroke is regulated by the ratio of buffer volumes at top and bottom of the stroke. In this engine the pressure at the top of the stroke is rather more than twice that at the bottom, and at the bottom the pressure in the buffer is always reduced to less than the boiler pressure, the pressures above and below the high-pressure piston being equal at about half-stroke. The cylinders are completely and easily drained, owing to the valves being at the bottom of each cylinder, and the condensed water from the high-pressure does not go to the top of the low-pressure at all, but is thrown past the opening and is drained away from the recess above the low-pressure valve. Near the bottom of the low-pressure cylinder small grooves are cut in the sides, so that any water which may collect above the low-pressure piston may drain to the underside at the bottom of the stroke. A small right-angled stop-valve is placed at B (not shown in figure), and connected up to steam on the boiler side of the main stop-valve. This valve serves several purposes. In the first place, the engine is started by means of it, as it starts it slowly and allows plenty of time for the engine to heat up and water to drain away. Secondly, even if the water does not drain away completely, the valve being open acts as a relief cock. Of course, when the engine has got up some speed, the main valve is opened and this one shut. Thirdly, if the engine should ever be pushed for some extra power, this valve allows some steam to the high-pressure cylinder during the

* Paper read before Glasgow Technical College Scientific Society.

Digitized by Google

whole of the up stroke, and also to the top of the low-pressure cylinder during the down stroke, but is shut off by the piston valve from communicating with the bottom of the low-pressure cylinder on the up stroke.

This engine works single-acting at all speeds up to a very high maximum, and at all loads without an air buffer. The air-buffer engine soon reaches a maximum speed, beyond which it is impossible to go without increasing the dimensions of the buffer. Owing to the peculiar distribution of steam in this engine, and also to the fact that the buffer may have a pressure more than twice the boiler pressure, if desired, very high speeds can be obtained. At A a small relief valve is placed: this prevents the buffer pressure becoming too high. Water collecting in this space, of course, reduces the volume of the buffer, and raises the pressure until it becomes great enough to open the relief cock, when the water is blown out. It is not very easy at first sight to see why this engine should be single-acting, as the valves are both at the bottom of the stroke, where, of course, the steam pressure is upward. A little consideration will, however, soon show why the resultant pressure should be always downward. will be seen that at 800 revolutions a pressure of 300lb. per square inch on the high-pressure piston would be required merely to neutralise the inertia forces—*i.e.*, without producing any pressure on the crank-pin at all; at 567 the inertia forces correspond to 150lb. per square inch. These inertia curves gradually approach, and between ordinates 5 and 6 cross the horizontal line, and from thence to the end of the down stroke (ordinate 10) exert a considerable downward pressure on the crank-pin. At the beginning of the up stroke (ordinate 10) the curves, being above the horizontal line, indicate 100lb. and 200lb. downward pressure for 567 and 800 revolutions respectively. They again approach the horizontal line, and between ordinates Nos. 15 and 16 cross, and from there to the end of the up stroke indicate a considerable upward pressure. To counteract this inertia curve and produce an even downward pressure on the cross-head pin, very high pressures are required at the beginning of the down stroke. These pressures ought to form a curve which would be the inverse of the inertia curve. To do this with an ordinary steam distribution, admitting steam to, say, half-stroke, would be impossible. The curve given by

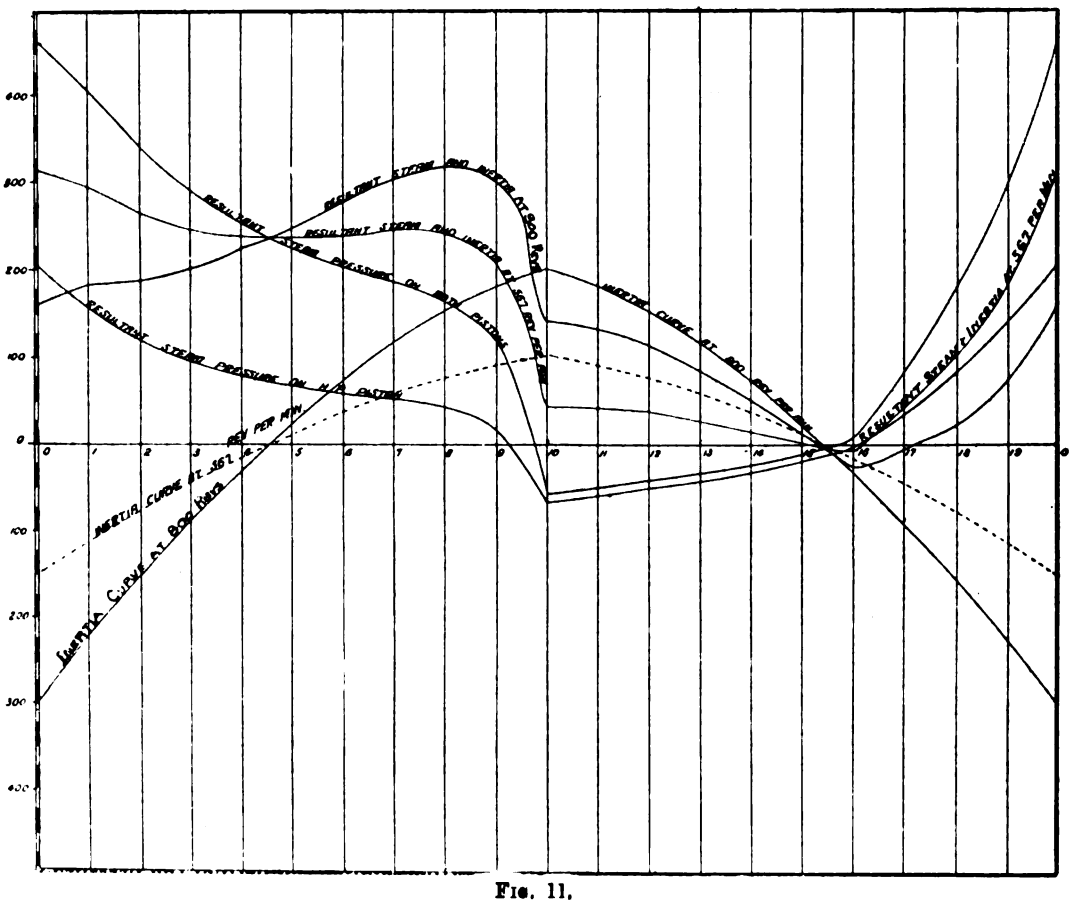

Fig. 11.

In order to assist you, might I, in the first place, rapidly run over the principal effects of inertia in the reciprocating parts with which we have to contend. Beginning at the top of the down stroke, very considerable pressures are required to start the piston, etc., on its downward journey. In this engine 300lb. per square inch would be required on the high-pressure piston if the engine were running at 800 revolutions, supposing no steam were acting on the low-pressure piston. As the piston travels down, these forces rapidly diminish, and about half-stroke vanish. During the second half of the stroke the inertia forces help the steam to propel the engine. On the up stroke the same effects take place, power being required at the beginning of the stroke to accelerate the parts. These inertia effects are shown in Fig. 11 for 800 and 567 revolutions. In this diagram all the ordinates above the horizontal central line correspond to pressures downwards, and *vice versâ*, and all pressures are plotted out in pounds per square inch of the high-pressure piston. These effects are traced during one complete revolution, beginning on the left-hand side at the top of the down stroke, while the beginning of the up stroke is at ordinate No. 10. From these curves it a steam cushion, however, almost exactly fulfils the requirements. In this engine both the high-pressure and low-pressure are under the influence of such a buffer, the high-pressure because of the steam buffer; the low-pressure because the volume of the high-pressure cylinder and the clearance on top of the low-pressure is expanded regularly without the admission of any fresh steam during the whole of the down stroke. The resultant steam

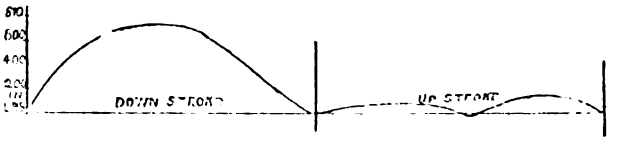

Fig. 12.

pressure on both pistons (the low-pressure referred to the high-pressure) is shown in Fig. 12, starting on the left of the diagram at about 475lb., and falling evenly till ·9 of the stroke, when the admission of fresh steam to the underside of the high-pressure and the equalising of steam on both sides of low-pressure piston causes it to drop suddenly,

Digitized by Google

till as the engine passes its bottom centre the balance of pressures on the pistons is upward. This upward pressure at the beginning of the up stroke is not great enough to lift the reciprocating parts off the crank-pin, and thus cause knock, but merely relieves the pressures on the crank-pin, etc. Between ordinates 15 and 16 the buffer pressure on the top of the high-pressure piston is equal to the steam pressure below, and at the same time the cut-off takes place in both cylinders, the result being that the difference of pressure on both sides of each piston increases very rapidly, and the curve shoots up till the end of the stroke. If, now, the inertia curve and the curve of resultant steam pressure on both pistons be combined, a curve showing the net effect on the crank-pin is obtained. This curve rises towards the end of the down stroke at 800 revolutions, but at 567 revolutions the curve is almost perfect, keeping nearly horizontal during the down stroke, almost relieving the bearings during ·9 of the up stroke, and suddenly rising at the end so as to have a useful pressure to begin the down stroke. Unlike other engines which rely on steam cushioning, this engine is single-acting from no load up to full load, for as the steam pressures fall under the high-pressure piston, the buffer pressures remaining constant become more effective, and at no load take up all the cushioning. Governing is effected by an inner rotating sleeve in the high-pressure valve, throttling the steam immediately on its entry into the cylinder. As there is no valve chest or receiver beyond the control of the throttle valve, the governing is very sensitive.

I arranged with Prof. Barr, of Glasgow University, to test the engine. Unfortunately, he was ill with influenza at the time, so I determined to test it myself, all data being taken by independent observers. We had a condenser at atmospheric pressure, and all steam was weighed by means of a pair of beam scales. The brake was an ordinary rope brake, but in order to prevent it getting too hot, water was kept running on it. Indicator cards were taken by a McInnes indicator, and no allowance was made for the fact that the cylinders were not lagged, and that the high-pressure valve was leaking more than 50lb. per hour with engine standing. Of course, this was not all loss, but was an uneconomical way of using the steam. On account of the excessively small fly-wheel, we were unable to get the full power out of it, so I am compelled to take the mean pressure referred to the low-pressure piston, and compare the results with Willans at the same mean pressure. The result was that at 32·5lb. mean pressure 21·9lb. of steam were used, and Willans at 33lb. (slightly more economical) used 22·8lb., or a difference of ·9lb. in favour of this engine. This same engine of Willans at full power—*i.e.*, 46lb. mean pressure and 158·5 boiler pressure—used only 19·19lb. per indicated horse-power. Had we been able to get full power from this engine, the steam consumption might reasonably be expected not to exceed 18·5lb. per indicated horse-power non-condensing, and at 150lb. pressure. The mechanical efficiency was very high, being 92 per cent., partly due to special pains which were taken to secure good lubrication, to the use of almost frictionless packings, and to the favourable conditions of bearing pressure on the up stroke. Unfortunately, a crack developed under the flange of the low-pressure cylinder, which prevented any further trials until a new cylinder could be made, when we hope to obtain the full power results.

THE PHILOSOPHY OF DYNAMO DESIGN.

(Specially contributed.)

INTRODUCTORY.

The title adopted for these notes has been suggested by Prof. Tilden's "Chemical Philosophy," a work which deals not so much with the actual reactions which occur, but rather with the principles underlying all chemical work, and which must be fulfilled in every successful experiment, So, in the present instance, the writer has no intention of adding to the numerous works which treat of the actual designing of dynamo-electric machinery, but, confining himself to the case of continuous-current machines, his intention is to lay more fully before the student some of the various points which must be constantly borne in mind by the successful designer.

The ground to be covered will therefore not include the actual dimensions required of armature, conductors, magnets, commutator, or shaft, as these are essentially only details, not principles. In all branches of scientific work the main or first principles upon which the particular branch under consideration rests will be generally found to be not only few in number, but also very easily to be understood, although the true reason of why a principle exists—such as, for instance, why a current should flow through a wire cutting lines of force—may be so hidden as to have been beyond solving up to the present: so in dealing with dynamo design the main principles are three in number only, and are as follows:

The first, due to Oersted, the Danish philosopher, and discovered in 1819, is that the passage of an electric current along a wire creates an external magnetic field. From this discovery has been derived the additional discoveries that if a wire be wound in the form of a helix or solenoid, this solenoid will behave like a magnet, and that if the wire be wound round a core of soft iron or steel, the strength of the magnet will be enormously increased. The north and south poles of this solenoid will depend upon whether the coil is wound right-handedly or left-handedly, and according to which end of the coil the current enters. A simple method of determining which is the north pole is that

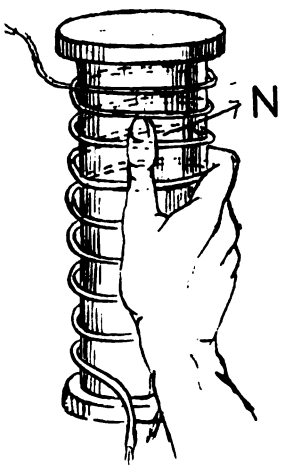

FIG. 1.

shown in Fig. 1. Place your hand on the coil with the thumb at right angles to the palm, and with the fingers pointing in the direction of the flow of the current through the coil; then the thumb will point towards the north pole. This great principle is the foundation of all electro-magnetism, and is of the utmost importance for a right understanding of many of the complex problems which arise in the course of dynamo design.

The second principle, due to Faraday and discovered in 1831, is often stated to be that if lines of magnetic force be cut by a closed coil or wire, a current will be generated in that coil. These lines may be cut either by moving the coil across the lines or moving the lines across a stationary coil. Vast as is the importance of the above principle in dynamo design—and it is on this principle that all modern machines are built—yet in the study of the philosophy of dynamo design the result which he derived from his first experiment is of equal value. From this experiment he found that a current is induced in a coil of wire if currents be started or stopped in neighbouring coils. The importance of this will be seen later when treating of the self-induction of the armature and its effect upon commutation. From this it was an easy step to the proof that a current is induced in a coil cutting lines of force, and that the value of the E.M.F. of this current will depend upon the number of lines cut in unit time. The assertion that the value of Faraday's first experiment is of equal importance to the latter part of this second great principle in the study of the philosophy of dynamo design must be taken in the spirit in which it is made—namely, that since all present-day machines are built upon this

Digitized by Google

principle of generating an E.M.F. by means of cutting lines of force, this principle (derived from his subsequent experiments) has become almost an axiom, and is so well known to every electrician as to almost entirely overpower the first experiment from which it was derived, so that this first experiment is not only lost sight of, but the relation of the two is constantly forgotten, and when the study of armature reactions is commenced the relationship of the two has to be relearned, and is often considered by many as a new property, and the connection between the two parts of the one principle is only acquired laboriously and with difficulty. When a wire cuts lines of force so as to induce a current, the direction of the flow of the current may be easily found by holding the right hand as in Fig. 2, with the thumb and first two fingers all at right angles to each other. Then, if the thuMb is pointed in the direction of the Motion, and the FORE-finger in the direction of the lines of FORCE, the seCond finger will give the direction of the Current.

The third principle is that the current which flows through a wire varies directly as the E.M.F. and inversely as the resistance. The importance of this principle, commonly known as Ohm's law, from its discoverer, cannot be overestimated, and, as will be seen from the section on commutation, its due appreciation, especially when the resistance is very low, is of the utmost value. This law is very often written $C = \frac{E}{R}$, but the student should also know it equally as well as $E = C\,R$ and as $R = \frac{E}{C}$.

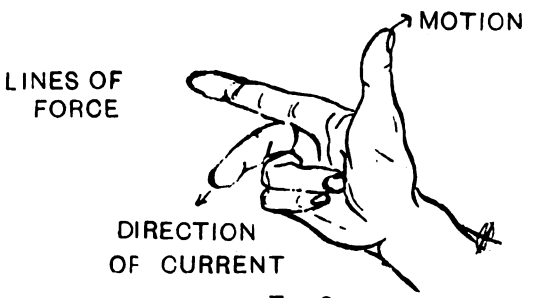

FIG. 2.

The above are the three fundamental principles, without a knowledge of which a discussion of the behaviour of a dynamo would be useless. There are, however, some secondary principles, which, while not of the same great importance, have such a value that the designer should constantly bear them in mind. The first of these is the fact that the pole of a magnet will induce opposite polarity in the end of a piece of iron or steel held near to it, to which is akin the fact that like polarities in magnets repel and opposite polarities attract each other. Another secondary principle is that known as Lenz's law, and is to the effect that the action of self-induction is such as to oppose the starting of any current along a wire and to maintain a current which is stopping. This action is very similar to that of inertia in mechanical work, where, for instance, the mass of a flywheel has a tendency to oppose the wheel being set in motion. The wheel, however, once revolving, the momentum of it will oppose the stopping, even to the extent of causing it to make many revolutions even after the motive force has been removed. Although the effect is exactly similar, it must be very clearly borne in mind that the cause is distinctly different. The dimensions of inertia are $M\,L\,T^{-1}$, while the dimensions of current are $M^{\frac{1}{2}}\,L^{\frac{1}{2}}\,T^{-1}$. Prof. Tait, in his "Properties of Matter," defines inertia as "passivity or dogged perseverance," and adds, "matter is, as it were, the plaything of force, submitting to any change of state that may be imposed on it, but rigorously persevering in the state in which it is left until force again acts on it." The tendency of self-induction to oppose a starting current and maintain a stopping current is of a different nature, and the distinction is of great importance. From our first primary principle we learn that the passage of a current along a wire creates an external magnetic field, and the lines of this field cut the wire while the field is being formed; from our second primary principle, we learn that when a wire cuts lines of force, a current is generated or induced in the wire. Now, the current induced by the wire cutting the lines of force due to its own external field is in the opposite direction to a starting current, and so prevents its instantaneously attaining its full value, while the current induced by the collapsing lines of force of the external field when a current is broken is in the same direction as the original current, and so tends to maintain the current for an appreciable length of time. The effects of this action will have to be be dealt with more fully when dealing with the question of commutation.

Another point which must be always kept in sight, is that if the current has two or more parallel paths along which it can flow, it will flow along each of these paths in inverse proportion to their resistance. This is evident from Ohm's law, for if we have an E.M.F. equal to E, and three paths whose resistances are respectively R′, R″, R‴, the currents which will flow along these various paths are

$$C' = \frac{E}{R'}; \quad C'' = \frac{E}{R''}; \quad C'' = \frac{E}{R'''};$$

and $$C = C' + C'' + C'' = \frac{E}{R'} + \frac{E}{R''} + \frac{E}{R'''}$$

$$= \frac{E\,(R'\,R'' + R'\,R''' + R''\,R''')}{R'\,R''\,R'''} = \frac{E}{R}.$$

The writer makes no apology for dwelling thus fully upon these first principles and elementary laws; he is quite aware that they form the groundwork of the theoretical and practical training of every electrician; but while admitting that almost every electrician could repeat the various laws, etc., and even demonstrate their truth in practice, yet when it comes to a complex problem, such as the solution of a peculiarity in the behaviour of a given machine, he has too often found that all laws and all principles are thrown to the winds. Suppose, for example, a machine sparks badly with its normal load, owing to faulty design; how often in place of going over the design step by step, and reasoning the matter out from first principles, is the procedure one of "we will try this: it cured such-and-such a machine"?—a machine which probably was designed to work under vastly different conditions. And when this haphazard guess chances to remedy the evil, the designer considers himself a heaven-sent electrician; when it fails, an equally well-thought-out alteration is suggested, and so on, until finally the machine is thrown on the scrap heap, or an expert who does not despise first principles is called in, and by quiet reasoning finds the error which has been made.

A dynamo may be designed in three ways. The first is by the method of pure guess work; magnets of a certain size are taken and such a quantity of wire is wound on them as may be thought advisable. The same method is adopted with the armature. A machine so designed may run well; certainly it deserves not to. By this system, after one or two failures, a saleable dynamo will be arrived at, although the actual speed and the desired speed will often be very divergent, and its general behaviour will more often than not leave much to be desired. The second method is to copy as nearly as possible the designs of some first-class efficient machines, and then so long as the machines have to work under the same conditions the results will be satisfactory, but the further apart these conditions are the less happy will be the results. The third and correct method is to design the machine by the light of past experience, not only experience in dynamos of practically the same output, but to utilise as far as possible details and information and experience gained from all sizes and classes of machines; for experience and the knowledge gained from previous work is half the battle, and then to apply the primary principles and laws to the design and see that all are in accordance with them. The student must remember that while the first principles are facts, deductions made from them without warranty of practice are theories, and that one ounce of practice is worth a pound of theory; and hence when in making a design a deduction is made and a certain result is anticipated, care should be taken to note in the finished dynamo if this deduction is borne out in practice, and so can be utilised in future as experience.

Digitized by Google

We will now assume that our dynamo is designed and built, and see how our first principles and the deductions therefrom should be applied to it.

(To be continued.)

THE EDISON AND SWAN COMPANY'S CATALOGUE.

We have received from the Edison and Swan United Electric Light Company, Limited, a copy of the new catalogue which they are now issuing. The catalogue is very much larger than any of the company's previous lists, and contains information concerning almost every electrical fitting and accessory that is made. The catalogue commences with a description of the action of an electric bell and diagrams of electric bell circuits for various purposes, such as burglar alarms, station signalling, etc. These descriptions naturally lead up to the bells supplied by the company, of which there are a large number. The ordinary quality bells listed range in price from 2s. each to

FIG. 1.

7s., these latter having conical-shaped gongs. There are also medium and best qualities made, these latter being very expensive. Special bells, wound for long-distance operation, are also sold. There are also supplied chime bells, ship's bells, circular bells, damp-proof iron bells, etc. A novelty in this direction consists of a metal-frame electric buzzer. This is a very small arrangement of similar construction to an electric bell, which does not give a sharp ring (which is in some cases considered objectionable), but makes a buzzing sound. Other bells are supplied which are in shape similar to the ordinary handbell, and of these the Bow bell, which we illustrate in Fig. 1, is noticeable for its neat appearance. The price of a 3in. bell of this kind is only 6s. The patent watertight bells which the firm manufacture are also well worth a notice, the internal arrangement of these being kept entirely free from dust or damp. Electrical indicators naturally come next in the list, there being a large variety of these, including semaphore indicators. Small complete bell sets are then listed, following which come electric bell-pushes and bell-pulls in seemingly endless variety, there being no less than 38 pages of the catalogue devoted to these.

FIG. 2.

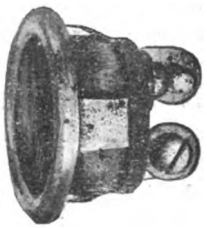

FIG 3.

The prices range from the low price of 6d. upwards. It is useless to describe the commoner forms of wood, china, and brass pushes, which are so well known, but of these the company manufacture many different kinds. Some of their table pushes and paper-weights are rather artistic, and that shown in Fig. 2 should be rather popular just now, when Britons generally think so much of the British lion. Fig. 3 shows a very neat little push, which is shown full size, and which will fit into a ⅜in. hole, and is provided with spring clips to keep it in place. Fire-alarms, Leclanché cells, and batteries of all kinds are then dealt with, and also galvanometers, current detectors, binding screws, tools, etc. Lightning conductors and an automatic speaking-tube complete this valuable list of electrical fittings.

EDINBURGH ELECTRICITY ACCOUNTS.

The accounts of the Edinburgh electric lighting station for 1899-1900 have just come to hand, from which it appears that the total amount expended on capital account to date has been £595,655. 8s. 1d. We give herewith the revenue account, abstract of general balance-sheet, and statement of electricity generated, sold, etc.:

THE INSTITUTION.

Was it not Froude who first pointed out the great difficulty of obtaining historic accuracy? If our memory serves correctly, Froude pointed out that seldom or never did a listener hear a similar account of an incident which the various individuals who described it witnessed. The difficulty which exists in obtaining an absolutely correct account of what happens to-day is enormously intensified when the description is of an incident which occurred a hundred or a thousand years ago. When one comes to think over these difficulties in getting accurate information, it becomes doubtful how far any historic incident has been truly and faithfully described. Still, when the narrator of a historic incident is a witness thereof, or has had access to living witnesses, the probability as to the truthfulness of his statement is greater than it would be if the narrator was writing or speaking in after years. Having these views of Froude before us, and applying them to electrical matters, it would seem to be wise in the concluding year of the century that, as far as possible, the true history of the various developments of electrical applications should be authoritatively recorded. It seems to us that the institution, above all others, upon which this work should devolve is that of the Electrical Engineers. Many of its members have either been largely concerned in the development of applied electricity, or have been closely connected with those who have been so concerned. We would suggest, then, that the Institution, perhaps, in addition to its ordinary work, collect and publish a series of monographs upon the various applications of electricity, which should, as far as possible, crystallise the history of these applications. It may be, as Mr. Fahie has shown in his researches, that too much prominence has been given to certain individuals, and insufficient attention has been paid to the work of others, and such things being discussed now could more easily and more faithfully be made straight than if left to future historians. During the last year or so the Institution has been exceedingly active. It has, so to speak, thrown out its arms and embraced the provinces, bringing within its fold the whole of the electrical talent of the kingdom. Would it not be possible to further increase this activity, and appoint a small committee to deal with each special branch of electric engineering, to bring together materials for a series of monographs which should be complete and, as far as human action is concerned, authentic. It has always been said that scientific men are seekers after truth, and yet it is well known that the true history of applied science is very difficult to obtain. The ordinary man, if asked the position of Stephenson in the development of the locomotive, would probably answer that it was he, and no one else, to whom the world is indebted for a great step in its progress. Others would say that Stephenson would not have been able to do what he did had he lacked the work of others to assist. Coming back to electrical matters, practically the whole development of applied electricity has been during the last seventy years of the century. What Faraday commenced

Digitized by Google

others have carried on, till the end of the century shows an enormous development in all electrical matters. We have made this suggestion for what it is worth, and must leave the Institution to consider the matter. While, however, on the subject of the Institution, might we venture upon one complaint? Its meetings during the session are held for the purpose of discussing questions of interest to the profession. To many the mere question whether the meeting lasts half an hour longer or half an hour shorter is of no importance, but, on the other hand, we think there should be a rigid adherence to the unwritten rule which ends the meeting at a particular time. We have referred to this point before and pointed out that comparatively few members live within walking distance of the place of meeting, most being dependent upon trains for getting home. Many of the members, again, are engaged in business, and, though it may be a singular trait in the character of an Englishman, like to keep fairly regular hours. If, however, the time of concluding the discussion is an unknown quantity, and happens to be exceptionally late, many who would have foregathered together and had a friendly chat are unable to do so; for although the ostensible reason for meeting together may be to hear and formally to discuss the paper, there is no doubt that what is of almost equal importance is the informal talk which happens before and after the conclusion of the meeting. Generally this informal discussion must be after the meeting, hence the greater necessity of not making the meeting too long. This, then, is the second question that we put forward for consideration. The decision on both matters must be left to the Institution, though the latter lies very much in the hands of the President.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE PATH OF THE SUN.

SIR,—I see a review of my work, "The Path of the Sun," in your issue of Sept. 28 by Mr. Edwin Edser, but as it strikes me, it is more an attempt to exhibit the superior knowledge of Mr. Edser than a review.

To follow his elementary instructions on points undisputed is needless, and I will confine myself to what he describes as my fallacies. For example, he remarks that "it is concluded [*i.e.*, by me] that the revolution of the nodes of the sun produces a conical motion (of the earth's axis) of 47deg. *about an axis perpendicular to the ecliptic.*" Now, as it is admitted on all hands that the conical motion of 47deg. does take place, where is the fallacy? It must be in my statement that this is produced by the revolution of the nodes of the sun; but if that be the fallacy, Mr. Edser presents no argument to prove it so, and I have only Mr. Edser's authority for it, the value of which I am unable to estimate, but he seems to think it sufficient. It is impossible, however, to reply to an oracular assertion.

"But," he says, "another fallacy lies behind. We are first told that the revolution of the *nodes of the sun* carry the earth's axis round once in every revolution, and then that the revolution of the sun itself does the same thing." Well, the revolution of the nodes of the sun and the revolution of the sun itself are equivalent phrases, the former being produced by the latter, and there need be no misunderstanding on the point.

While the earth is making its annual journey round the sun, the sun has moved on a certain distance in its orbit, with the result that the sidereal position of both orbs is altered and the place of the crossing of the sun over the equator has moved on with the sun—that is, the nodes have sidereally shifted. That is a description of what actually happens, without regard to any theory, and the geometry of the statement it is impossible to dispute. Now, whether I describe the movement of the earth's axis to be produced by the revolution of the nodes or by the revolution of the sun, no one who understands the actual movements of the two bodies can misunderstand either statement, as both have the same meaning.

Just a word or two as to Newton's explanation of precession. I have historically proved precession to have been nothing more than a conjecture of Hipparchus. Newton adopted this conjecture as true, neither he nor anyone else being able to give any other explanation; and Newton in his turn conjectured that the conic movement of the earth's axis was produced by the action of the sun and moon upon the protuberance at the earth's equator. He then proceeded to calculate the proportional influence of each in producing this movement. That is all he did; and there is nothing whatever existing in the nature of proof but that calculation. Now, my contention is that a calculation cannot prove the nature of a movement. Mathematically you may prove the velocity, size, force, mass, or weight of a celestial body, but to prove anything relating to a quality, condition, or attribute by figures is impossible.

To settle the matter, let Mr. Edser take Newton's figures and show how they prove that the motion of the earth's axis is that of a spinning top, instead of a gliding motion round the circle of the sun, as I state it to be. If he do, I will grant him the palm of superiority.—Yours, etc.,

WM. SANDEMAN.

Hollin Bank, Oswaldtwistle, Lancs., Oct. 8, 1900.

ELECTROMAGNETIC INDUCTION.

SIR,—As, after his letter in your issue of the 12th inst., silence on my part would evidently be misinterpreted by Mr. Dunton to his own advantage, I trust that you will excuse me for once more trespassing on your space.

I should be considerably annoyed to think that I had failed to convince Mr. Dunton of the genuineness of the mare's nest which he has found, but, judging from his last letter, he is apparently still wriggling under his original delusion. His attempt to put the "electrical engineer's bible" in the scales to bring the balance down in his favour, only emphasises more clearly his persistent inability to grasp the difference between defining the behaviour of a closed circuit moving entirely in an uniform magnetic field and a closed circuit moving only *partially* in a magnetic field. The behaviour of the former is dealt with by Dr. Thompson in the paragraph quoted by Mr. Dunton, and the behaviour of the latter is dealt with by Messrs. Slingo and Brooker in the paragraph also quoted by Mr. Dunton. Both paragraphs are perfectly correct.

Quoting from p. 27 of the *fourth* edition (I do not possess a fifth) of "Dynamo-Electric Machinery," Dr. Thompson, in dealing with the former case, says: "It is, however, necessary that the moving conductor should, in its motion, so cut the magnetic lines as to alter the number of lines of force that pass through the circuit of which the moving conductor forms a part. If a conducting circuit—a wire ring or single coil, for example—be moved along in a uniform magnetic field, as indicated in Fig. 14, so that only the same lines pass through it, *no current will be generated.*" But this is only another and far simpler way of stating that it is impossible to so move a closed conducting circuit in an uniform magnetic field, that the algebraical sum of the E.M.F. impressed thereby on the component parts of the circuit is not zero *unless* the number of "lines" passing through it is increased or decreased. The impressed E.M.F. must essentially be produced by the conductor itself *cutting through* the "lines," whatever the shape of the conductor may be, and the fact that current can only be induced in a closed circuit, moving entirely in an uniform magnetic field, by varying the number of "lines" passing through it, only follows in a secondary manner from a property common to all closed circuits—viz., that the algebraical sums of both the vertical

Digitized by Google

and horizontal components of such circuits are zero. In the statement of Messrs. Slingo and Brooker condemned by Mr. Dunton, this property does not apply, however, as it deals with the E.M.F. impressed on a conductor (not a closed circuit) moving in a magnetic field, and the current which results *when* the ends of that conductor are connected together outside the field.

If, however, Messrs. Slingo and Brooker's statement is wrong, then the following statement on p. 26 of "Dynamo-Electric Machinery" is also wrong: "Now, Faraday's principle is nothing more nor less than this, that by moving a wire near a magnet, across a space in which there are magnetic lines, the motion of the wire, as it cuts across those magnetic lines, sets up magnetic whirls round the moving wire, or, in other language, generates a so-called current of electricity in that wire." Personally, I fail to see anything wrong with this latter statement, and yet I venture to think that Mr. Dunton, by his own methods of reasoning, could have made out a far better case of "slipshod language" from this statement than from the one which he chose. I am, of course, aware that the quotation of "slipshod" statement from one authority is no justification of a parallel statement from another, but since Faraday and Dr. Thompson are the prominent authorities whom Mr. Dunton has brought forward to pull him out of the pit into which he has fallen, this method should carry some weight with him.

I freely admit that I have "not the ability to perceive the glaring contradiction" which Mr. Dunton mentions, but sincerely trust that I am not, as he suggests, alone amorg your readers in this respect.

In conclusion, I must apologise for having written at such length on a subject which must have lost its interest long since.—Yours, etc., F. JOHNSTON.

THE FOUNDATION STONE LAYING OF THE HACKNEY ELECTRICITY AND REFUSE DESTRUCTOR WORKS.

The ceremony of laying the foundation stone of the Hackney electricity and refuse dust destructor works, performed by Alderman W. H. Dickinson, D.L., chairman of the London County Council, yesterday (Thursday) afternoon, was attended by a large gathering of guests invited by the Vestry of the parish of St. John-at-Hackney. The event marks the commencement of another important link in the chain of what may be termed borough electricity supply stations which surrounds smaller London. Shoreditch, Islington, and Poplar, all immediate neighbours of Hackney, have already inaugurated supplies—Poplar, indeed, quite recently—but although later to make a definite move, Hackney certainly does not intend to be ousted so far as the initial boldness of its undertaking is concerned. It is proposed to expend close on £250,000 upon the joint schemes as an initial instalment, of which sum about £225,000 will be absorbed by the electrical portion.

The site of the new works is in Millfields-road, Lower Clapton, N.E., and the proceedings yesterday afternoon were presided over by Mr. GEORGE OGAN, chairman of the Electric Lighting Committee, who, after a prayer had been offered up by the Hon. and Rev. A. G. Lawley, M.A., rector of Hackney, for the success of the undertaking, said that in starting this electrical undertaking they had taken a step in their municipal history. The trader who refused to keep his establishment well lighted and fitted went to the wall, while the trader who kept his store in good order got on well. It was the same in municipal life, and the parish which did not provide a good system of lighting for its inhabitants soon lost numbers of them, who went where they were better looked after. In consequence, the Vestry had taken the matter in hand, and had determined to have a light worthy the parish, and for this reason they had given the matter into the hands of Mr. R. Hammond, who was one standing very high in his profession.

The CHAIRMAN then called upon Mr. Robert Hammond, M.I.C.E. (consulting engineer to the Vestry), to briefly describe the works, in responding to which request

Mr. HAMMOND said, after reading the programme, he had wondered if the chairman would have had the boldness to ask him to speak. This was in consequence of a report in one of the papers to be placed under the stone, in which it was stated that the most foolish thing the Lighting Committee had done had been to appoint an engineer. However, in spite of all temptations, they had called upon an engineer, and he would speak a few words with reference to the undertaking. He would first say the works were devoted to two purposes, one being the destruction of all the refuse in the borough of Hackney, and the other was the production of electricity. They were going to send the current through 100 miles of cables, and the pressure would be ready for the use of those who cared to use it in some 50 miles of streets. The pressure was going to be sent out by some 5,000 h.p., and it would try very hard to come home again. This could only be done through the little lamp filaments, which incidentally it would heat white hot, and thus light their lamps. In the case of motors for factories, it would be forced to drive them. They hoped when the undertaking was in working order it would not cost the borough a penny. In the other part of the undertaking they were going to dispose of the refuse of Hackney in the only way in which it should be disposed of—namely, by burning it.

Alderman DICKINSON was then presented with a trowel and mallet by the architects, Messrs. Gordon and Gunton, and, after declaring the stone to be well and truly laid, said it was a pleasure to him to take part in such a function. He had just laid the foundation stone, and he hoped it would be the beginning of a great undertaking. It would be, he was sure, the end of a great controversy. They had buried under the stone a number of papers, and he thought he might also say they had buried the dissensions and disagreements on the subject of electricity which had taken place in the Vestry. He then referred to the history of the electric light undertaking in Hackney. As long ago as 1893 the Vestry had obtained the order which empowered them to supply Hackney with electric lighting, and after certain delays a committee was appointed in 1895 for the purpose of carrying the order into effect. In 1897 some difference arose as to how it should be carried out, and the committee came to the conclusion that the powers should be handed over to some private company who undertook to supply at a cheap rate, but at the same time taking all the profits. The people of Hackney, however, by a Vestry election prevented the arrangement being carried out. A resolution was then passed to the effect that the order was the property of the ratepayers, and that the Vestry should use the same for the benefit of the ratepayers, and the Vestry refused to sell the order to any company. This was the right course to pursue, and no one should doubt its expediency. They had the advantage of consulting one of the most able all-round electrical engineers (Mr. R. Hammond) in regard to this question, and he was not only able to advise them as to the practical methods of generating the electricity, but as to the way in which to make the undertaking pay. His report was a remarkable monument of arguments for the carrying out of electrical supply by public bodies. He showed in that report the example of Leeds, in which, by a majority of one, the committee came to the same conclusion as that of the Hackney Vestry and sold the order to a company. This company for four years made very large profits, and the Corporation then bought it out at a very high price. Five years ago there were only two bodies in London carrying out their own electric supply. Now there were 12, and before long 19 would be supplying, or about to supply, electrical energy. The local authorities had become convinced that it was wiser for them to carry out the works than to put it in the hands of companies. Of the two undertakings in London from which results could be obtained for any length of time—Hampstead and St. Pancras—both were making the works pay. The cost of the new works was to be some £250,000, of which £225,000 was for the electrical works and the remainder for the refuse destructors.

Digitized by Google

The price to be paid for the energy was very low, in fact, the lowest in London—namely, 4d. per unit for private lighting, 3d. per unit for public lighting, and 2d. per unit for power supply. These charges would allow the light to compete with the gas company's charges. It was expected that they should realise a profit of £1,000 in the first year, this gradually increasing up to £14,000 in the fourth year. It depended, however, entirely on whether the ratepayers supported the Vestry in the matter. He would recommend them, when the electric light was available, to shut off the gas from the premises and get the Vestry to put them in a free installation of electric light by a free-wiring arrangement. He trusted the electrical enterprise in Hackney, like the stone, was "well and truly laid" as a municipal enterprise.

Mr. T. HOSGOOD then proposed a vote of thanks to Alderman Dickinson, which was seconded by Mr. W. L. BEURLE, supported by Mr. SMITH, L.C.C., and adopted unanimously.

Alderman DICKINSON then acknowledged the vote of thanks.

Other speakers followed.

The following notes on the undertaking, prepared by Mr. Robert Hammond, the consulting electrical engineer, were appended to the order of proceedings presented to each guest:

The buildings are being erected by Mr. John Greenwood, from the designs of Messrs. Gordon and Gunton, F.R.I.B.A., Finsbury House, Blomfield-street, London, E.C. They are situated upon a site of about five acres in Millfields-road, Hackney, and adjoining the grounds belonging to the London County Council. The site allows for ample means of extension, and has the advantage of a frontage to the Lea River Canal, which will give economical facilities for the supply of fuel and the shipment of the clinker material. The engine-house will be 130ft. by 50ft., and is designed in bays with arcading, the walls being lined with an ivory-white glazed brick dado and surbase. In connection with this engine-house there are switch-rooms, cable-rooms, engineers' offices, lavatories, workshops, and stores, also an extensive basement for the engine-beds and cable arrangements. The upper floors of the building contain an accumulator-room, 143ft. by 30ft., with covered platform and trap-doors to loading space below, together with workmen's and foremen's quarters, baths, lavatories, w.c.'s, and kit bins.

The buildings will form a very handsome block in brickwork, with red and malm brick facings and stone dressings. The roofs will have steel principals with boarded covering, also felting and blue slates. There is an ample provision of skylights, which will be glazed with patent glazing. The chimney shaft in connection with these works has an internal diameter of 10ft., and will be carried up to a height of 200ft. with firebrick linings and the necessary lightning conductors, and has been specially designed in regard to appearance and as an ornament to the neighbourhood. The buildings have been designed to afford sufficient space to accommodate 6,000 h.p. in boilers, engines, dynamos, and switch gear. Sufficient land has, however, been acquired to permit of a further 6,000 h.p. being added by an extension of the present buildings.

In the first instance it is not proposed to erect plant of more than 3,000 h.p., this, with the accumulators, being sufficient to supply current for about 50,000 8-c.p. lamps alight at once, after allowing for a sufficient reserve. There will be six boilers of the Babcock and Wilcox water-tube pattern, three being fired by the refuse destructor gases, and three being placed in the permanent boiler-house. The ordinary working pressure will be 180lb per square inch, but the refuse-fired boilers will be capable of working up to 250lb. per square inch to counterbalance any irregularities in the firing.

The engines are of the triple-expansion type, and are designed for a working pressure of 175lb. per square inch. Each engine is arranged to drive two dynamos direct without intermediate gearing, and a common condenser and cooling apparatus is provided for each pair of engines. One pair of engines are being built by Messrs. Belliss and Morcom, Limited, of Birmingham, and one pair by Messrs. Willans and Robinson, Limited, of Rugby, the dynamos being supplied by Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne.

A battery of accumulators, having a capacity of 2,800 ampere-hours, has been ordered from the Tudor Accumulator Company, Limited, of London, the primary object of the battery being, as far as possible, to store for future use the energy developed in the refuse destructor at times when it would otherwise be wasted.

The working pressure on the distributing mains in Hackney has been fixed at 480 volts across the outer conductors of a three-wire system, so that the actual pressure of supply for ordinary purposes will be 240 volts. With a view to utilising the power derived from the refuse destructor to the utmost, and at the same time meeting a probable demand for power as well as lighting, the direct-current system of distribution has been preferred.

The electricity mains are of ample section to meet any probable requirements for some time to come, and are being laid or will shortly be laid in about 50 miles of streets. Arrangements are also about to be concluded by which mains can promptly be laid in almost any street or road in the district in which there is any demand for electricity for lighting or for power purposes. The first contract for cables was placed with the British Insulated Wire Company, of Prescot, and the work of laying the mains is now in progress. The mains are of the triple-concentric type throughout, and are laid in stoneware and iron troughs filled in solid with a bituminous compound.

For public street-lighting arrangements have been made for the erection of 320 arc lamps, which will be run nine or ten in series across the outer conductors of the three-wire system, provision being made for controlling all the lamps from the electricity works. The lamp pillars will be spaced from 50 to 60 yards apart, and the posts have been designed so that the top of each lamp is about 21ft. above the ground.

The refuse destructor consists of 12 furnace cells, capable of burning a maximum of 150 tons of refuse per 24 hours. Arrangements have been made for the automatic handling of the refuse, so far as this is possible, from the moment it is tipped at the works to the time when it emerges from the furnaces in the form of clinker. The surplus energy will be utilised for driving the plant in the electricity works. The elevators, blast fans, and feed pumps will all be driven by electric motors. The contract for the destructor has been let to Messrs. Hughes and Stirling, of London.

MISTAKES IN THE RATING OF INCANDESCENT LAMPS.*

BY ARTHUR J. ROWLAND, MEMBER.

A 16-c.p. lamp is a such a common article of commerce and in such general use that we all recognise it when we see it, or think we do, either by the size of its bulb or the length of the filament or both. Very few people go beyond such mechanical identification except for the extra assurance they gain by a look at the manufacturer's label. Some, indeed, presume to tell that a lamp is of a given candle-power by looking at the brightness of its filament or by considering the general lighting of a room; but it need scarcely be said that an estimate formed by such a method is utterly worthless, since one is too much influenced by contrasts in brightness, or deceived by the temperature at which a given filament is burned, to really tell anything at all about the candle-power.

The importance of exact knowledge of the candle-power of incandescent lamps is at last being recognised among lamp users generally. One of the signs of this in the present times is the great number of photometers recently set up and used outside of laboratories. Certain standard measurements are made with these, which are good so far as they go, but commonly many important things are quite passed by unnoticed. Not only should the user of incandescent lamps want to know that the

* Paper read before the Franklin Institute.

Digitized by Google

lamps he buys really have the candle-power marked on them, and that they maintain their candle-power properly as they grow old in service, but he ought to know and fully understand a number of other things regarding the real candle-power and watts per candle-power of the lamps he uses. Some of these seem to have quite escaped notice, and their importance is so great as to merit careful consideration.

What a 16-c.p. Lamp ought to be.—Let us first enquire into just what a 16-c.p. lamp ought to be. That it should be one which gives a light equal to that of 16 candles in the direction in which the light is useful seems a natural and fair definition. A little careful observation of lamps as they are installed shows that at least 85 to 90 per cent. of those used are put in place with base upward or tipped end downward, and it is the light which comes from this tipped end of the lamp which is useful. In cases where the lamp is installed in a different position, either the lamp is subordinated to some artistic feature of the electrolier, or the lamp is installed "side on" to better keep it out of the way. So it comes that the light we ought really to want to know about, the light we ought to measure, is that coming out of the end of the lamp. Or, at least, it is sure that, if we call the axis of the lamp a line through it from the middle of the base up to the sealed-off tip, the light of value is that coming into space below a plane perpendicular to the axis, half-way along its length. We can never use more light than this, since for satisfactory lighting the sources must be above us, and in real service we make use of much less, as will be presently shown. Should we take the average candle-power of all the light rays into space below the imaginary plane just defined, this would be called the mean hemispherical candle-power, just as the average candle-power of all the light rays given by the lamp in every direction is called to the mean spherical candle-power.

The Importance of the Light from the Tipped End.—The placing of lights is to-day being made much more intelligently than by the old rules of so many 16-c.p. lamps per 100 square feet of floor surface, or per 100 cubic feet of room to be lighted. Some certain amount of illumination is now striven for, and a proper distribution of light rather than of lights is sought.

In a great deal of lighting one tries intentionally to give illumination concentrated about particular points. For example, in lighting a library it is the library table which is to be brightly lighted; other parts of the room need little more than the scattered rays otherwise useless, which reach them directly from the light source or after reflection. The light rays in poor planes and the reflected light which comes from the table, the walls, and objects in the room, though contributing little to the important light, serve to break up shadows and produce diffusion. Almost the same thing would be true of the lighting of a bedroom, where the light should be concentrated about the bureau or dressing table.

In quite a different sort of lighting, still the same things hold true. Take the lighting of a factory or mill for example. The light must be on the machines or work, and be very good there. That which gives the room its general lighting is waste light from the light sources. To light the whole room as brightly as the machines would be too costly to be practical. For such lighting, let us consider what rays are useful and what rays waste light. If the lamp hangs directly above the thing to be lighted, and its area be not more than 5ft. by 5ft., no rays of light beyond 30deg. from the axis of the lamp will be useful, and the higher the lamp is hung, the less the angle in which the useful light is found.

A second sort of lighting is that in which a uniform distribution of light is required, as in concert halls or auditoriums of various sorts, and in shops for the sale of merchandise. A fundamental principle in this class of lighting is to use many sources of small candle-power each, all so placed that the light from them is directed downward, with perhaps a little diffused side light to break up the shadows, especially in small interiors. The lighting engineer is forced to use single lamps to procure this, except in large rooms, and they are nearly always installed base upward. The light from the tipped end produces the light of value.

A third sort of lighting is for decorative purposes, but that is so very especial and foreign to considerations of candle-power at all in most instances as to merit no consideration here.

The light below the lamp—that from the tipped end—is then the important and useful light in all practical cases. This is true, too, not only from the specific cases cited, but where large electroliers with many lights are used as well; for in such cases the lamps are usually flared out, with axes at some angle approaching 45deg., in which case high candle-power from the tipped end and low from the sides of the lamp would contribute to a good, even illumination of the room.

The importance of procuring high candle-power below the lamp has been recognised a long time. But what expensive and roundabout methods have been taken to procure it. It is very common to use reflectors to increase the amount of light in the direction below the lamps. While reflectors have their place in lighting, and an important one, too, for most purposes they are exceedingly poor and are used in ignorance of the effects they produce or because no better device for light redistribution can be had. No matter whether the reflector covers the lamp or not, no matter whether it is of porcelain, a glass mirror, or a polished metal surface, it inevitably cuts the light off absolutely in some directions and so directs it in others as to produce sharp shadows and brilliant lighting contrasts. In satisfactory lighting contrasts of light and shade are always avoided, and by producing diffusion most shadows are lost. Other devices, like McCreary shades and specially shaped incandescent lamps having a reflector incorporated with the lamp, have faults precisely the same as reflectors. Holophanes, with their prismatic and accurately formed surfaces, turn the light downward, and at the same time diffuse it by refraction, so that on all artificial lights the distribution of the light, and the lighting therefore, is improved by their use. A holophane gives a redistribution of light immeasurably better than a reflector always. If an incandescent lamp is installed base down, holophanes or reflectors must be used on it or the lamp be valueless in supplying really useful light.

The common use of such devices is evidence that the ordinary incandescent lamp does not give as much light below it as is required there. Is there, then, a bad light distribution from them? An examination of modern lamps will tell us.

Filament Types and Candle-Power Distribution.—There are five different types of filament in use to-day by various prominent lamp manufacturers, and in most cases a filament type indicates the product of a certain manufacturer who has adopted that as the one used in his standard lamps. These typical filaments are enough different from each other to show interesting individuality. I have classed them as follows: (*a*) straight U-shaped filament; a type rapidly passing altogether out of use. (*b*) Single curl filament; a type much used, having a circular loop in the filament midway of its length. This type was originally designed to render filaments stiffer and less liable to bend without an anchor, and also to shorten the lamp bulb. It was found to give a better distribution of light than type *a*. (*c*) Long curl anchored filament; a type differing from type *b* in that the loop is long in the direction of the lamp axis, and is anchored to the part of the lamp where the leading-in wires pass through the glass. (*d*) Double filament; a type which uses two filaments like type *a*, set so the current passes through them in series, the filaments being in planes approximately parallel. (*e*) Double-coil filament; a type like *b*, except that there are two turns in the coil instead of one.

Besides being typical in the matter of general form, the light distribution observed from these various filaments is also typical. It is, however, considerably influenced by the exact relation of different dimensions in the filament itself used by particular firms; as, for example, the diameter of a coil or the spread of the filament shanks. Results below are therefore departed from somewhat if different makes of lamps had been used in the tests.

Fig. 1 shows average candle-power values from lamps of

Digitized by Google

each of the different types. The arrows indicate the direction from which the candle-power was measured, and the number gives the candle-power. These values are true averages of the types shown. In the averages struck no "freak" lamps were included. The five types are each represented by the product of some prominent lamp maker. All the lamps are rated 16 c.p., all were in the standard bulb used by the manufacture of a type, and, as it happened, all were 3·5-watt 110-volt lamps. A careful inspection of the figure shows one that the form of filament has a most important relation to the candle-power distribution, as, of course, it must, since the candle-power delivered in a given direction is determined almost wholly by the amount of filament length visible from that direction. A filament of type *a* shows only the end of the U when one looks in at the tip, and so the candle-power must be low, even if the U be broad. A double filament must show low candle-power for the same reason; and if the filament loops are narrow and the legs of the filaments straight, as they were in the lamps of the make tested, the candle-power may be even lower out from the tipped end than for a filament of type *a*. A filament with a coil in it shows much more projected length when viewed from the lamp's end, and so gives comparatively high candle-power in that direction. We see, then, that a 16-c.p. lamp is very different in the candle-power it gives in various directions, and very different in a given direction with difference in type of filament. That lamp which gives most useful light is undoubtedly the best. Hence there is no question but

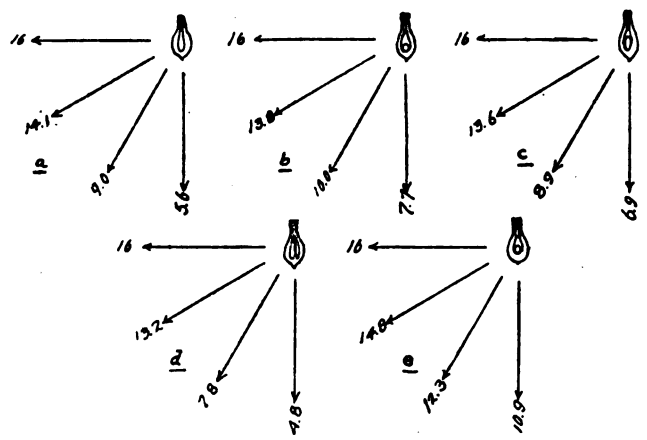

FIG 1.—Showing Average Candle-Power Distribution from Incandescent Lamps of various types *a*, straight U-shaped filament; *b*, single-curl filament; *c*, long-coil anchored filament; *d*, double filament; *e*, double-coil filament.

that the 16 c.p. lamp with filament of type *e* is a far better lamp for general lighting purposes than any other. It is almost beyond belief that this has escaped notice in all the years incandescent lamps have been made and used, and yet it has been so. I first had my own attention called to the matter by the Shelby Electric Company, for whom I was making some tests of candle-power. It is their lamps which I show as type *e*. In an attempt to find whether in the past anyone had attached importance to the light coming out from the tipped end, I have been surprised to note how, over and over, this or that experimenter or lamp manufacturer has been on the verge of the discovery and then passed it by. One of the most recent cases I have noticed is that of a lamp manufacturer who advertised sign lamps with "all the light from the end," but seems never to have thought that this would be the right sort of lamp to use as his standard product.

Fig. 2 gives the relative amount of useful light from filaments of the different sorts expressed in per cent. of the light given by the double-coil filament (type *e*). The Shelby lamp (type *e*) for which data is given was made tipless—that is, the sealing-off after exhaustion was not done, as usual, at the tipped end. The gain in candle-power by omitting the tip, so far as tests which I have been able to make indicate, is about 12 per cent. The loss in tipped lamps is probably due to light absorbed through the thicker glass at the tip and partly to reflection and refraction of light into useless directions, which otherwise might have been saved to be useful.

What folly it turns out to be to use special devices to turn the light downward when the lamp itself can have the filament constructed so as to give a proper light distribution. A design of filament for incandescent lamps so they will give large candle-power from the tipped end is second in importance only to satisfactory efficiency, and maintained candle-power with fair average life.

FIG. 2.

Filament.	Light in given direction in per cent. Vertically downward.	30deg. from vertical.
Type *e*	100	100

,, *c*	63·7	72·4
,, *b*	70·6	81·3
,, *a*	51·4	73 2

Illumination by Lamps using Filaments of Different Types.—A large amount of light streaming from the end of the lamp is only useful if it produces a proper illumination. In Fig. 3 is plotted the illumination of a level surface 5ft. below a 16-c.p. lamp of different makes, the distribution being shown one way out from the lamp only. A single representative lamp was taken of each of three important sorts, and the candle-power as marked on the diagrams determined for the light given in each of the directions shown by the arrows. The illumination was then calculated in candle-feet, and this plotted vertically from the base line. The solid curved line bounding the shaded area runs through the points so found, and all vertical distances from the base line give the amount of illumination there. Some of the values found are marked. Thus, for

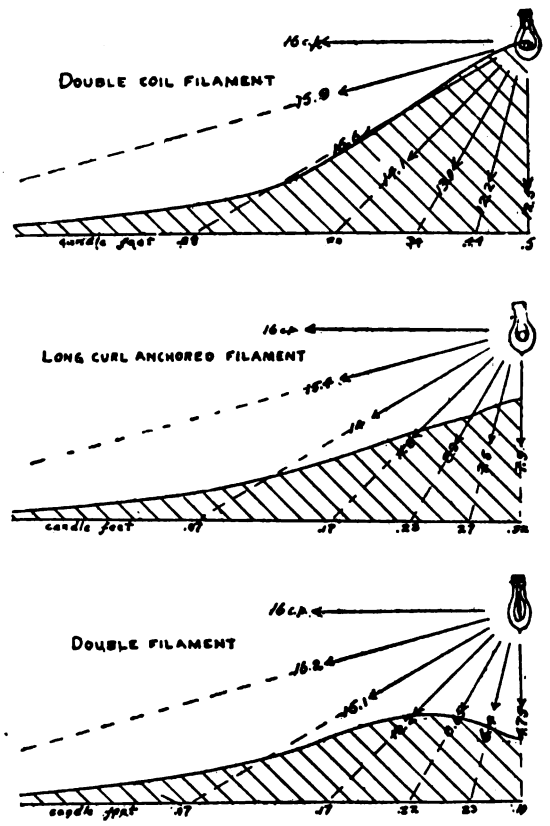

FIG. 3.—Illumination by Filaments of different types.

the long curl anchored filament ·32 of a candle-foot is procured at the surface illuminated by the ray giving 7 9 c.p., 27 by the ray giving 7·5 c.p., etc. The candle-foot unit is the common one—that is, an illumination of 1 candle-foot is that of a surface everywhere 1ft. distant from a light giving 1 c.p. in every direction. A surface 2ft. distant at every point from such a light source would have an illumination of quarter of a candle-foot. A first look at the diagrams would seem to indicate that the double-filament lamp is best, since it gives more uniform illumination than either of the others. In any case we need not concern ourselves with the light received from rays making an angle greater than 45deg. with the vertical, since up to this angle a circular area 10ft. in diameter, above the centre of which the lamp hangs, is being lighted. Under the lamp the light is most valuable, and there we want to get most light. The double-coil filament turns out

Digitized by Google

then to be by far the best form. If in lighting an interior the lamps were hung separately and placed about 6ft. apart, the evenness of the illumination produced would be about the same for lamps having double-coil filaments, or lamps having long curl anchored filaments, but the amount of illumination procured from double-coil filaments would be so much greater that they are much to be preferred. We are assuming all along that 16-c.p. lamps, as the manufacturers call them, are in use. If lamps were placed 15ft. apart, the distribution of light with double-filament lamps would be very good if an even distribution is desired, but the average illumination would be low.

(To be continued.

POWER GENERATION—COMPARATIVE COST BY THE STEAM-ENGINE, WATER-TURBINE, AND GAS-ENGINE.*

BY JOHN B. C. KERSHAW, F.I.C.

There is no question of greater importance at the present moment to those engaged in the management of our manufacturing industries than that of power generation. The supremacy which the steam-engine has so long enjoyed is now assailed from two sides. The water-turbine and the gas-engine have become dangerous rivals. During the past 10 years a most remarkable development of hydraulic power has been taking place on the Continent of Europe in France and Germany, and in America at Niagara. The aggregate amount of power at the present date generated from falling water forms no inconsiderable portion of the total power utilised in manufacturing industries; and two years ago it was estimated by the author to be between 236,000 h.p. and 350,000 h.p. On the other hand, gas engineers have been busily engaged in working out the problems presented by large gas-engines and by the utilisation of the waste gases of blast furnaces. Gas-engines up to 650 h.p. have been built, and have worked smoothly and economically; while at Seraing, in Belgium, and at other places the blast furnace gases have been utilised for driving the engines which supply the blast. The question, therefore, which the engineer now has to settle when deciding upon the site and locality for a new factory, or when deciding upon the system of power generation to adopt for extensions of the old, is no longer so simple as when only one method of power generation in large units was open to him. It is no doubt true that the choice between the three possible sources of power is one which in many cases will be settled purely by local considerations; and the proximity of a large waterfall or of an extensive coal-field to the factory, will be held to point to the turbine or to the steam-engine as the most economical power generator. In a great number of cases, however, especially when the decision of the engineer covers the choice of a site for the factory, the problem is capable of no such easy solution; and the most economical source of power can only be determined after an exhaustive study of comparative costs data. The aim of the writer in the present paper has been to collect and arrange in comparable form some of the more important figures bearing on the cost of power generation. Full references are given to all the original articles from which these figures are drawn. Taking the best figures for each of the three sources of power dealt with above, and bringing them all to a common basis of comparison—namely, the cost of the electrical horse-power year of 8,760 hours—the author obtained the figures given below:

TABLE VII.—Comparative Costs of Electrical Power.

Source of power.	Lowest cost per E.H.P. year of 8,760 hours— Estimated. £ s. d.	Locality.	Actual. £ s. d.	Locality.
Water	1 5 5	Canada	1 19 0	Switzerland
Steam	4 18 8	North England	4 9 7	United States
Gas (producer)	5 0 0	England	—	—
Gas (blast furnace).....	4 1 7	Germany	—	—

The figures in the table support the opinion, now generally held, that water when developed without excessive capital expenditure is the cheapest source of mechanical or electrical energy. When, however, the hydraulic engineering expenditure has been heavy, or when the power after generation has required to be transmitted over long distances, the margin between the relative costs of water and steam power is greatly narrowed, and in some cases disappears. Electrical energy generated by falling water is costing more at Rheinfelden, at Zürich, and at Buffalo than it would cost in South Lancashire if generated by steam power in large units; and the margin between the actual charge for power at Niagara and the estimated cost of steam power in large generating stations in South Lancashire is only 12s. 1d. per electrical horse-power year. In this connection it is interesting to note that the charge for electric power in Buffalo is 13s. 6d. per electrical horse-power year higher than at Niagara; and the excessive charge to small consumers in the same city (£25. 11s. per electrical horse-power year) would seem to indicate that the cost of transmission between Niagara and Buffalo represents at least 20s. per electrical horse-power year on the power sent into that city. Turning now to a consideration of the relative position of gas power, the question of the practicability of large engines may be taken as settled. If they do not cost excessive sums for maintenance and repairs, large gas-engines, in conjunction with coke ovens and blast furnaces, may entirely alter the present position of affairs; and the new industries which at present are being established in the neighbourhood of water-power stations may find themselves in severe competition with similar manufactures carried on in the coal and iron districts of the older manufacturing countries. It has been calculated that 2,000,000 h.p. is annually wasted in the gases issuing from the blast furnaces of the United Kingdom. If these waste gases could be industrially utilised in the manner suggested, we should to a large extent be compensated for our lack of natural water power. But blast furnaces demand coke, and coal beds are exhaustible, so that even if this source of mechanical and electrical energy be tapped it can only postpone, but not avert, the final triumph of the waterfall and of the turbine.

* Abstract of paper read before the British Association at Bradford.

LIGHT RAILWAYS.

The Commissioners have held an enquiry at Kidderminster into the application of the Kidderminster and Stourport Electric Tramway Company for powers to construct a line from Kidderminster to Bewdley, with a branch to Franche. At the close of the enquiry Lord Jersey said the Commissioners understood there was an agreement as to the line going up to a point by the railway bridge at Wribbenhall. They would go and inspect the route beyond, and did not propose to come back to hear any further statements. They would consider the matter, and then communicate with the County Council and with the promoters.

The Light Railway Commissioners have granted an application for a light railway, between five and six miles in extent, known as the Wales and Laughton light railway. The proposed line commences at a junction with the Great Central Railway near Kiveton Park, and extends through the parishes of Wales, Todwick, North and South Anston, and Dinnington, to within a short distance of Laughton-en-le-Morthen.

The Light Railway Commissioners have held an enquiry into the application for the deviation of a line at West Hartlepool and the application for an order to authorise the Durham and district light railways promoted by the British Electric Traction Company, and granted the application.

The Light Railway Commissioners have held an enquiry respecting the proposed light railway in the Nidd Valley, from Pateley Bridge to Lofthouse, and granted the application.

An enquiry has been held by the Light Railway Commissioners with respect to an application by the British Electric Traction Company for an order to construct a light railway in and between South Shields and Jarrow, to be called the Jarrow and South Shields Light Railways.

FORTHCOMING EVENTS.

FRIDAY, OCT. 19.

Institution of Mechanical Engineers.—At 8 p.m., at Institution House, Storey's gate, first monthly meeting. Paper on "Observations on an Improved Glass Revealer for Studying Condensation in Steam Engines and Rendering the Effects Visible," by Mr. Bryan Donkin.

SATURDAY, OCT. 20.

Glasgow and West of Scotland Technical College Scientific Society.—At 7 30 p.m., at 38, Bath-street, Glasgow, presidential address by Mr. David Home Morton, M.I.C.E., M.I.M.E., on "The Standardisation of Machinery.'

FRIDAY, OCT. 26.

Physical Society.—At 5 p.m., at Burlington House, exhibition of experiments illustrating certain phenomena of vision, by Dr. Shelford Bidwell, F.R.S.; and papers on the "Concentration at the Electrode in a Solution, with special reference to the Liberation of Hydrogen by the Electrolysis of a mixture of Copper Sulphate and Sulphuric Acid," by Dr. J. S. Sand; and "Electromotive Force and Osmotic Pressure," by Dr. R. A. Lehfeldt.

Institution of Junior Engineers.—At 8 p.m., annual general meeting at Westminster Palace Hotel.

SATURDAY, OCT. 27.

Institution of Junior Engineers.—At 3 p.m., visit to the Millbank Station of the London Hydraulic Power Company, Millbank-street, Westminster.

Digitized by Google

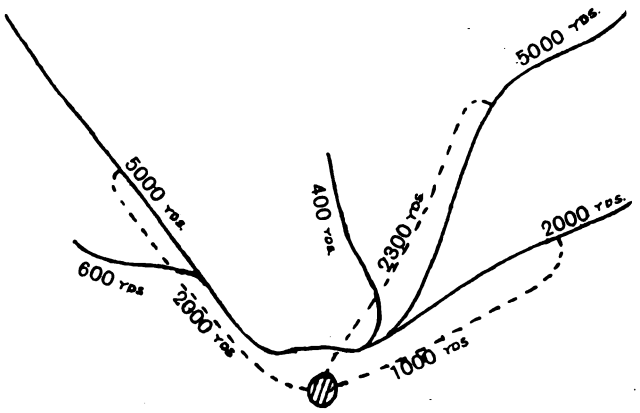
QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

317. Describe the best and cheapest form of main and distribution switchboard suitable for a small private station of two 65-kw. steam dynamos at 110 volts; first, with necessary switching arrangements for accumulator charge and discharging; and, second, without same.—K. M. K.

318. In a traction scheme, as per appended sketch, would it not be advisable to feed the trolley wires at the station in



addition to the feeders, or would it be best to transmit all the energy through the feeders and not tap on to trolley wires at station ?—ARMATURE.

ANSWERS.

Question No. 311.—What is the advantage gained by setting the cranks of a small compound vertical engines at angles other than 90deg.—for instance, about 145deg.

Best Answer to No. 311 (*awarded* 10*s.*).—In the case of high-speed engines such as are in general use for the direct driving of dynamos, a small flywheel is sufficient to maintain adequate regularity of speed. The analysis of the turning moment acting on the crankshaft is of no practical importance except to the builder, who has to design the parts and bearing surfaces to suit. The high speed, however, causes the inertia forces, which increase as its square, to be of considerable importance. In the case of a two "line" engine, the best arrangement of the cranks is at 180deg., in which position the force tending to lift the engine twice in each revolution is a minimum. The importance of this force may be judged from the fact that in the case of a two-line engine, in which the moving piston lines weigh 420lb., the stroke being 9in., and the ratio of connecting rod to stroke 2·4, this force amounts to 1·2 tons at a speed of 350 revolutions a minute. For infinitely long connecting rods this force vanishes. There remains a periodic rocking force about a horizontal axis at right angles to the centre line of the engine and midway between the cylinder lines, due to one piston going up while the other goes down. The third inertia force, due to the weight of the crankpin and lower part of the connecting rod at right angles to the other two, is of no importance.

In the case of a slow-speed engine of about one quarter the angular velocity, the inertia forces will be of much less importance in spite of the heavier moving parts, and even turning moment is of greater importance.

In the case of a two-line engine this is best accomplished by placing the cranks at right angles. This is the usual arrangement in marine, mill-driving, and locomotive work. Some such arrangement is necessary if the engine is to be self-starting in every position, especially if it has to do so against its load. In the case of electric generators this is not the case, so the cranks may be in the same plane. The three-line engine with cranks at 120deg. is practically perfectly balanced, and is self-starting in any position. Mention may be made of Mr. Webb's four-cylinder compound locomotives. These have four cylinders driving the same axle. The inside and outside cranks on one side of the engine are opposite and at right angles to the other pair. This gives a much better balanced engine than the usual arrangement of two cranks at right angles, and incidentally has greatly simplified the valve gear of the inside cylinder.

The case cited of two cranks at 145deg. is a compromise of the two types. It gives an engine which is self-starting and which is of a more even turning moment than one with cranks at 180deg., while the inertia forces will not be so large as would be the case if the cranks were at right angles. Engines running at a speed at which this arrangement might be desirable are not common. Engines either run too slow or else they are able, as in the case of electric generators, to be run up to speed before the load is put on, in which case a two-throw with opposite cranks or a three-throw engine is preferable.—E. H. R.

Answer to No. 311 (*awarded* 5*s.*).—To appreciate the advantages aimed at in setting the cranks of compound engines at angles other than 90deg., it is desirable to discuss first those cases where the cranks are opposite each other, and at an angle of 90deg. respectively. When the cranks of a compound engine are fixed opposite each other, both pistons are at the end of the stroke at the same time, and the larger, or low-pressure cylinder, valve is admitting steam to that cylinder during the same time that the high-pressure cylinder is releasing its steam. Thus there is a

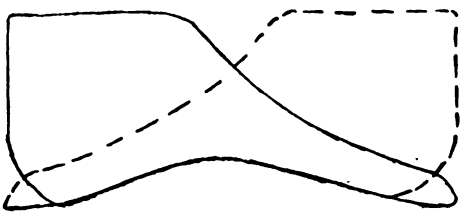


FIG. 1.

free passage for the steam to escape from the latter cylinder, and a continuous flow of steam from the high to the low pressure cylinder. Under these conditions it is not necessary to provide a receiver space between the two cylinders, and the engine can be designed to have the cylinders placed as close together as practicable, thereby allowing of a compact type of engine. With the cranks

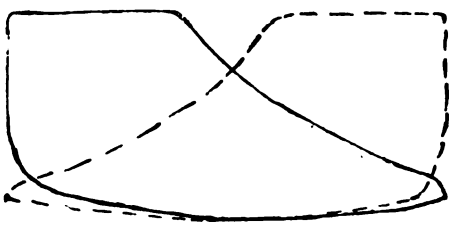

FIG. 2.

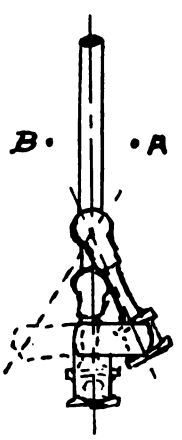
set at an angle of 90deg. to each other, however, the larger piston, neglecting the obliquity introduced by the connecting rod, is at the middle of its stroke when the smaller one is about to release its steam. Now, should cut-off to the low-pressure cylinder occur before half-stroke, a receiver becomes desirable to exhaust the high-pressure cylinder steam into, as the low-pressure cylinder is not taking any steam away. If, however, the engine is of a compact type and no special receiver space has been provided, and merely the unavoidable space between the high-pressure cylinder and the low-pressure valve utilised, the pressure in

Digitized by Google

this confined space would increase, comparatively to the terminal pressure, too high, and since the back pressure in the high-pressure cylinder depending upon the receiver space, this pressure would also be high. In fact, the exhaust line of the high-pressure diagram would take the form shown in Fig. 1, where a considerable rise about mid-stroke is shown. With the cut-off in the low-pressure cylinder about or somewhat after half-stroke, the rise of pressure, of course, would not be so pronounced. In Fig. 2 the form of the high-pressure diagram for cranks set opposite each other is given for comparison. It will be seen, therefore, that a better distribution of the steam can be effected with the cranks opposite each other, and if this were the only factor to consider, that method of setting the cranks would be the best to adopt.

We have, however, to study the effect of the angle between the cranks upon the twisting moment, and here an angle of 90deg. is a distinct advantage. For if twisting effort diagrams are constructed for crank angles of 90deg. and 180deg. respectively, it will be found that there is a more uniform twisting effort when the cranks are set at 90deg. This is evident from a casual consideration only, for when one crank is exerting its maximum effort the other is practically on the dead centre, and the twisting effort is a minimum. Further, with the cranks opposite each other, both are on the dead centres at the same time, and there may, therefore, be a difficulty in starting the engine, and this tells unfavourably for cranks so set. The above considerations, therefore, lead designers to adopt some middle cause, and we find in consequence the cranks of compound engines set at various angles, ranging from 90deg. to 180deg., to each other in accordance with the ideas of the designer.—G. T.

Answer to No. 311 (*awarded* 5s.).—In all compound marine engines the cranks are set at 90deg. This enables the engines to be started without the aid of pinch bar or other appliances. They have also an almost even twisting moment on the shaft. Now there is a great disadvantage in this type of engine due to vibration. On referring to the diagram we will say that the centre of gravity of the



engine is A when one crank is pointing to right, but when one crank is pointing to left the centre of gravity will change to other side, say at B. This sets up vibration, which is very objectionable in towns. Now there is the well-known Belliss central-valve compound engine with cranks set at 180deg. This does away with the vibration nuisance; but there is a point where there is no twisting moment on shaft—viz., where the cranks are in line with the connecting rods. Then 90deg. from this position we have a maximum twisting moment. This necessitates a thicker shaft; also a heavy flywheel to keep a more constant speed, which a varying twisting moment does not give. The engine referred to has its cranks at about 145deg. This engine will partly combine the advantages of a more even twisting moment; also the vibration will be greatly decreased.—W. A. T.

Question No. 312.—Having a ring armature (laminated), 9½in. outside diameter, 5in. inside diameter, and 3¼in. deep, I wish to wind same as a step-down transformer for use on a 100-volt 60-cycle circuit so as to yield 40 volts from the secondary at its maximum capacity. What size of wire and number of turns will be required on primary and secondary? Would it be possible to subdivide secondary circuit so as to yield various voltages?

Answer to No. 312 (*awarded* 7s. 6d.).—

Let E_1 stand for E.M.F. of primary coil;
E_2 ,, E.M.F. of secondary coil;
S_1 ,, number of turns in primary coil;
S_2 ,, number of turns in secondary coil;
n ,, frequency = 60;
N ,, magnetic flux.

Then $E_1 = 4{\cdot}45 \times n \times S_1 \times N \div 10^8$.

Now, cross-section of iron $= \left(\frac{9\frac{1}{2} - 5}{2}\right) \times 3\frac{1}{4}$ square inches

$= 2\frac{1}{4} \times 3\frac{1}{4}$ square inches

$= 7{\cdot}3$ square inches.

For transformers, magnetic flux should be about 40,000 lines per square inch.

$\therefore N = 7{\cdot}3 \times 40{,}000 = 292{,}000$.

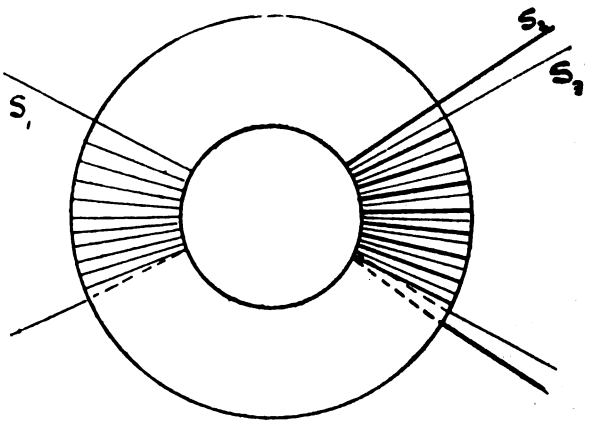
$E_1 = 4{\cdot}45 \times n \times S_1 \times N \div 10^8$;

$100 = 4{\cdot}45 \times 60 \times S_1 \times 292{,}000 \div 10^8$;

from which we get $S_1 = 128$ *turns (primary coil).*

Again, $\frac{E_1}{E_2} = \frac{S_1}{S_2}$, or, $S_2 = \frac{E_2 \times S_1}{E_1} = \frac{40 \times 128}{100}$;

$S_2 = 51{\cdot}2$—say *52 turns (secondary coil).*



Magnetising current:

$$\frac{4\pi}{10} C_m S = N \times \frac{l}{A\mu};$$

$\mu = \frac{B}{H} = \frac{5{,}000}{1{\cdot}66}$ { B = lines per square centimetre. H = magnetising force.

$= 3{,}000$.

Mean diameter of ring = 7¼in.

$\therefore l = \pi \times 7\frac{1}{4} \times 2{\cdot}54$cm.

$$\frac{4\pi}{10} C_m \times 128 = 292{,}000 \times \frac{22{\cdot}8 \times 2{\cdot}54}{7{\cdot}3 \times 6{\cdot}45 \times 3{,}000},$$

from which $C_m = {\cdot}53$ ampere.

Taking the magnetising current as about 4 per cent. of full load,

$\therefore$ full-load current (primary coil) = 25 × ·53 amperes
= 13·25 amperes.

Capacity of transformer = 100 × 13·25 watts
= 1,325 watts.

Taking hysteresis loss as one watt per 1lb. of iron, output of secondary coil = 1,325 − 45 watts = 1,280 watts.

$\therefore$ secondary current $= \frac{1{,}280}{40} = 32$ amperes.

Primary coils should be wound with $^{37}/_{24}$ S.W.G.

Secondary coil should be wound with $^{19}/_{18}$ S.W.G.

The secondary circuit can be subdivided, the number of turns in each of the secondary coils being obtained from the formula $\frac{E_1}{E_2} = \frac{S_1}{S_2}$. The secondary coils should be wound together (preferably) as shown in the diagram.—H. W. GEARE.

Digitized by Google

Answer to No. 312 (*awarded* 7*s.* 6*d.*).—In the case of a small transformer of this nature, probably only intended for experimental work, it is of more importance to consider the ease of winding than the efficiency. On this account the following windings have been arranged to make the core loss approximately equal to the C^2R loss instead of making it distinctly less, as is usual in commercial transformers intended to give a high all-day efficiency.

Two distinct windings are given below, the first being for an ordinary transformer with separate primary and secondary windings, and the second for an "auto-transformer" with the primary and secondary windings connected together in series, as shown diagrammatically in Fig. 1. This last, which gives nearly double the output of the first, is undoubtedly the type of winding to use for

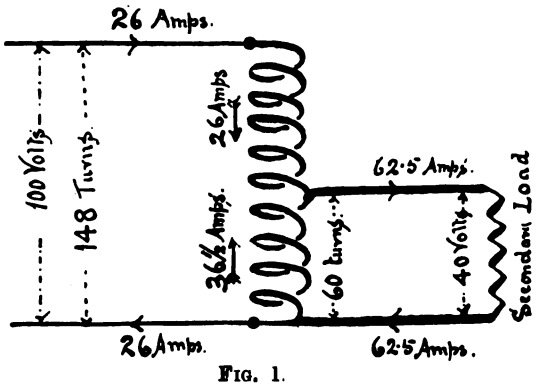


FIG. 1.

such a voltage ratio as 100 to 40 unless the transformer is intended for *boosting* purposes—*i.e.*, to give 140 volts by adding the 40 secondary volts on to the 100 primary volts, in which case the auto-transformer obviously cannot be used, as the two windings are already connected in series. In the following workings it has been considered better to use several small wires in parallel in place of a single large wire, as the difficulty of winding the latter on such a small core would be prohibitive. The several parallel wires can be either wound on simultaneously or each separately so long as the number of turns and total lengths of all the wires are kept alike. It is immaterial whether the primary or the secondary be wound on first.

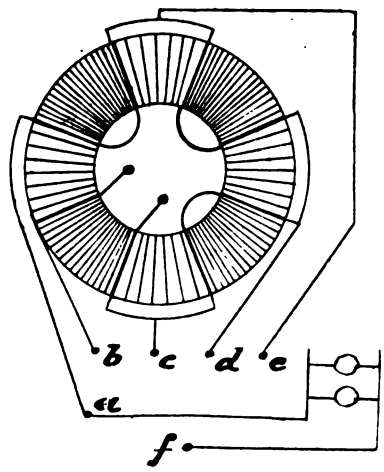
The wires given will be found to go on to the core fairly easily together with the necessary insulation, and should leave a hole about 2½in. or 3in. in diameter through the centre of the core when all is finished.

Proposed Windings.

Type.	Ordinary transformer.	Auto-transformer.
Estimated output with safe temperature rise (not enclosed in case)	40 volts, 37·5 amperes, or 1·5 kw.	40 volts, 62½ amperes, or 2·5 kw.
Primary wire	·104 D.C.C. (No. 12 S. W. G.) Two parallel.	·104 D.C.C. (No. 12 S. W. G. Four parallel for both primary and secondary windings.
Secondary wire	·116 D.C.C. (No. 11 S. W. G.) Four parallel.	
No. of primary turns	148 (or 296 single wires).	148 total turns (or 592 single wires). With a connection for the secondary output made after the 60th turn (as shown in Fig. 1).
No. of secondary turns	60 (or 240 single wires).	
Approximate C^2R loss in the whole of the windings	50 watts.	50 watts.
Induction density in the iron core	5,500 C.G.S.	5 500 C.G.S.
Approximate core loss (assuming average commercial iron).	45 watts.	45 watts.
Full load efficiency	94 per cent.	96 2 per cent.
C R drop	3 3 per cent.	2 per cent.
Core loss as a percentage of full load output.	3 per cent.	1·8 per cent.
Approximate weight of primary wire.	12½lb.	27lb.
Approximate weight of secondary wire.	16lb.	
Weight of core iron	45lb.	45lb.

With regard to the last paragraph of the question, connections can be made to the secondary winding (in either type of transformer) at as many points as is desired, and a corresponding number of different voltages can thus be obtained without difficulty.—Q.

Answer to No. 312 (*awarded* 5*s.*).—The armature core described may be utilised as a transformer core, though, its discs being most probably thicker than those usually employed in the latter case, the loss from eddy currents will be greater. The windings may be arranged in alternate primary and secondary groups round the ring as shown in the figure, where the primary connections and terminals are indicated inside and the secondary connections and terminals externally. By tapping the secondary



at four equidistant points as shown, voltages of 40, 30, 20, and 10 volts may be obtained, according as *b*, *c*, *d*, or *e* is switched on to *f*. The external circuit, connected to *a* and *f*, is conventionally shown with lamps, though, with these voltages, such would, of course, not actually be the case. As, however, this winding is less simple than the wrapping of the whole core by each coil, and is, moreover, productive of some magnetic leakage, we shall here design for the primary to be wound entirely round the ring, and to be overwound by the secondary coils.

Taking approximate dimensions, the outer diameter of core = 24·15cm., the inner diameter = 12 7cm., and the depth = 8·25cm. The plates are bound up by tape, which we may take as occupying a thickness of 2mm. On an assumption that the windings will be 1cm. thick on the outer circumference, and 2cm. thick on the internal, the total cooling surface is 2,137 square centimetres. Taking 87 per cent. of the core section to be actually iron, and 13 per cent. to be insulation between the discs, the iron section is 41·5 square centimetres, and the weight of the core is 19 kilos. With an induction of 4,500 C.G.S. lines, the total flux is $4{,}500 \times 41\,5 = 187{,}000$ lines. According to Kapp's experiments, if we let the temperature of the transformer be about 50deg. C. above that of the surrounding atmosphere, 42cm. of cooling surface are required for each watt dissipated in heat. Our surface will thus permit of 52 watts being lost altogether. At a frequency of 60, about 25 watts are expended in magnetising 19 kilos of iron to the induction chosen. We thus can lose 27 watts in the copper without over-running the cooling surface.

Now, by the usual formula for the E.M.F. induced (effective), and allowing a drop in the secondary of one volt, $41 = 4\,44 \times 187{,}000 \times 60 \times \text{turns} \times 10^{-8}$, whence the number of secondary turns is given as 82. The primary turns are $\frac{100}{41} \times 82 = 200$. Assuming the diameter of the wire to be 3mm, more or less, the length of primary wire comes out to 64m., and of the secondary to 29·5m., approximately.

One condition of efficiency—viz., that iron and copper losses should be about equal—has been satisfied. If we arrange to satisfy another, that the copper loss should be about equal in the two coils, the following ratio should hold:

$$\frac{\text{area of second wire}}{\text{area of first wire}} = \frac{\text{length of second wire}}{\text{length of first wire}} \times \frac{\text{second current}}{\text{first current}} = 2{\cdot}9.$$

Digitized by Google

Dividing the circumference by 200, and allowing ·25mm. for cotton covering, we find the primary wire may be 3·2mm. diameter, wound one layer deep externally and two layers deep inside the ring. The secondary may thus be 4·9mm. covered to 5·4mm., which can be accommodated if wound like the primary. From tables the resistances when hot are found to be: primary = ·18 ohm; secondary = ·031 ohm. The working conditions may now be tabulated from these data:

Load in watts.....	50	...	100	...	500	...	800	...	1,000
Primary current ...	·75	...	1·25	...	5·3	...	8·23	...	10·64
Secondary current...	1·25	...	2·5	...	12·5	...	20	...	25
Copper watts	·148	...	·48	...	·99	...	24 8	...	38 5
Iron watts	25	...	25	...	25	...	25	...	25
Efficiency per cent.	67	...	80	...	94·5	...	97	...	99
Temperature C. above atmosphere.	30°	...	32°	...	33°	...	48°	...	57°

By making connection to the secondary at three intermediate points, as in the figure, various voltages in steps of 10 may be obtained; or, of course, by tapping at a suitable length any desired E.M.F. under 40 volts.—ZERO.

ST. MARYLEBONE.

On Tuesday evening a special meeting of the members of the St. Marylebone Vestry was held at the Court House, Marylebone-lane, Mr. T. H. Brooke-Hitching, C.C., chairman of the Vestry, presiding, for the express purpose of resuming the adjourned debate on the motion of Mr. Edward White, L.C.C., that the Vestry now confirm that part of the minutes of Thursday, Aug. 2, 1900, which related to the proposed purchase of the St. Marylebone undertaking of the Metropolitan Electric Supply Company, and which empowered the Advisory Special Electric Lighting Committee to conclude negotiations with the Metropolitan Electric Supply Company for the transfer of its undertaking under the West London (Marylebone) Electric Lighting Order as embodied in the provisional agreement dated June 25, 1900, and signed on behalf of the company by Messrs. Harrison Cripps and T. Carr Saunders, and on behalf of the Vestry by the Vestry's delegation, Mr. T. H. Brooke-Hitching, Dr. J. Fletcher Little, and Mr. G. Paxton, it being a condition that the figures supplied by the Metropolitan Electric Supply Company be verified by a chartered accountant and an expert electrical engineer to be employed by the Vestry. The price to be proposed to be paid by the Vestry for the undertaking was £916,000.

The discussion was a lengthy one, occupying the attention of the Vestry for over three hours. Messrs. DUNN, PAXTON, W. SUTHERLAND, J. ANGLIM, and others spoke strongly in favour of the delegation's recommendation being adopted, contending that if the Vestry did so that it would have the electric light company's undertaking as a going concern at a reasonable price, and that they would soon see that they had a paying concern. The present lighting of the streets was a disgrace.

Sir EDWIN GALSWORTHY (chairman of the Metropolitan Asylums Board), Mr. G. R. H. STRINGER, Mr. MARTIN MORRIS, and others spoke strongly in opposition, and urged that it would be unfair for members, now that the Vestry was in a dying state, to undertake such a huge undertaking, and that such an important matter should have been left to the new borough council to deal with. It was contended, also, that the price asked was far above what ought to be paid. The company required £500,000 for the goodwill, and in less than 40 years the Vestry would have the undertaking, having to pay nothing for goodwill.

On the question being put to the vote the non-confirmation was carried by 31 to 26. A division was called for, and taken, but the voting was the same. The non-confirmation of the minutes being passed, the scheme proposed by the special committee falls through.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

St. Albans.—The Corporation invite offers for their electric lighting provisional order. Details in our advertisement columns.

Lowestoft.—The Corporation invite tenders for wiring the town hall. Tenders by Nov. 2. Details in our advertisement columns.

Heywood.—The Corporation invite tenders for wiring premises in Heywood. Tenders by Oct. 31. Details in our advertisement columns.

Belfast.—The Gas and Electric Committee invite tenders for various plant. Tenders by Nov. 23. Details in our advertisement columns.

London County Council.—The Council invite tenders for the supply, for one year from Jan. 1 next, of engineers' goods and electrical stores. Tenders by Oct. 29.

Palma.—The Municipality of this town, in the province of Baleares, Spain, invite tenders for the installation and maintenance of 60 arc lamps. Tenders by Oct. 30.

Swansea.—The Corporation invite tenders for the supply of electricity meters, demand indicators, and main fuses. Tenders by Oct. 29. Details in our advertisement columns.

Ayr.—The Corporation invite designs, specifications, and tenders for electric tramway cars with trucks and complete electrical equipments. Tenders by Nov. 1. Details in our advertisement columns.

Pemberton.—The Council invite tenders for boilers (preferably Lancashire), engines and dynamos, battery, switchboard, crane, and conductors. Tenders by Nov. 8. Details in our advertisement columns.

Whitechapel.—The Electrical Committee invite tenders for the supply of a hand-driven overhead travelling crane for their new electricity supply station. Tenders by Oct. 23. Details in our advertisement columns.

Cardiff.—Tenders are invited for slow-speed vertical engines, slow-speed generators, boilers, and economisers. Specifications, etc., may be obtained from Mr. A. Ellis, M.I.E.E., Old Post Office-buildings, Cardiff. Tenders by Oct. 23.

Grantown-on-Spey.—The Commissioners of the burgh invite tenders from electric light companies to supply electric light for public and private consumption within the burgh. Tenders by Nov. 6. Details in our advertisement columns.

Wolverhampton.—The Tramways Committee invite tenders for erection of car depôt, paint and repair shops, etc., at Cleveland-road. Plans, etc., may be seen at the office of Mr. J. W. Bradley, C.E., M.I.M.E., borough engineer, Wolverhampton. Tenders by Nov. 19.

Bradford.—The Corporation invite tenders for the construction and erection of a 30-ton electric travelling crane for their new electricity works, Valley-road, to operate on a 500 volt direct-current circuit. Tenders by Oct. 25. Details in our advertisement columns.

Cienfuegos (Cuba).—Tenders are invited for a service of public electric lighting for the above town. Intending contractors can present their estimates and state their conditions until Oct. 26. All enquiries and tenders should be addressed to the Secretary's Office in Cienfuegos, Cuba.

Glasgow.—The Executive Committee invite tenders for the wiring for arc and incandescent lighting and electric motors at the Glasgow International Exhibition, 1901. Full particulars can be had on application to Mr. Thomas Young, the engineer, 4, West Regent-street, Glasgow.

Dartford.—The Urban District Council invite tenders for the erection of an electric light station at Dartford, in accordance with drawings and specifications prepared by their architects. Specifications may be seen at the office of Messrs. Heaketh and Stokes, 110, Cheapside, E.C. Tenders by Oct. 20.

Lowestoft.—The Corporation invite tenders for the supply and erection of two water-tube boilers and fittings economiser, etc., pipework, etc., in engine and boiler house, and one 250 kw. steam dynamo (vertical enclosed high-speed engine). Tenders by Nov. 2. Details in our advertisement columns.

Glasgow.—The Corporation invite tenders for the supply of 1,000, 2,000, or 3,000 tons steel straight track rails; 100, 200, or 300 tons steel curved rails; 50, 100, or 150 tons steel fishplates. Specifications, etc., can be obtained from Mr. John Young, general manager, 88, Renfield street, Glasgow. Tenders by Oct. 23.

Leeds.—The Leeds Tradesmen's Benevolent Institute invite tenders for the installation of electric light required in alterations and additions to 41, Park square, together with three shops and business premises, Park lane, Leeds. Plans, etc., can be obtained from Messrs. Butler, Wilson, and Oglesby, architects, 12, East-parade, Leeds.

London (City).—The Streets Committee of the Corporation invite tenders for the hiring of a mechanically-driven dust-cart for collecting and removing the dust, trade refuse, and street sweepings from the City to the Corporation's depôt at Lett's Wharf, Commercial-road, Lambeth, S.E. Tenders by Nov. 10. Details in our advertisement columns.

London, S.E.—The Strand District Board of Works invite tenders for the construction, delivery, and fixing of an engine and dynamo, switchboard, etc., for their destructor works, Shot Tower Wharf, Commercial-road, Lambeth. Specification, etc., to be obtained at the offices of the Surveyor to the Board, between 10 and 12. Tenders by Oct. 24.

Kendal.—The Corporation invite tenders for building engine-house, boiler-house, accumulator-house, chimney shaft, offices, etc., in connection with the electric lighting station to be erected at the gasworks, Kendal. Specification, etc. may be seen at the office of the engineer, Mr. T. N. Ritson, A.M.I.C.E., Gas Offices, Parkside road, Kendal. Tenders by Oct. 29.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2,

Digitized by Google

1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

RESULTS OF TENDERS.

Walsall.—The tender of T. Tildesley, Willenhall, for erecting a transformer station in Pleck-road for the sum of £430 has been accepted.

Ayr.—The Lighting Sub-Committee have accepted the tender of Messrs. Bruce Peebles and Co. for two 200-kw. Belliss-Peebles traction generators, at £4,380.

Stafford.—The Electric Lighting Committee have accepted the tender of the Electric Construction Company, at £322, in connection with renewing the armatures and field coils of the dynamos.

Limerick.—The Town Council have received the following tenders for the erection of an electric generating station building at Frederick-street, Limerick: P. Bourke, Carr-street, Limerick, £2,650; M. Gough, Colooney-street, Limerick, £3,925.

Wigan.—The Corporation have accepted the following tenders: Estler Bros., London, steel poles and section pillars; Blackwell and Co., London, flexible bonds and castings; Bergtheil and Young, overhead construction material; Naylor, bracket arms.

Whitby.—The Urban District Council have accepted the following tenders in connection with the electric lighting: Carrick and Ritchie, travelling crane, £169; C. H. Parsons and Co., two steam dynamos, etc., £2,679; Tudor Accumulator Company, battery, £1,486.

Grays.—The following tenders have been accepted:

Danks, boilers	£2,325 0 0
British Schuckert Company, steam dynamos	2,147 10 0
Green, economiser	241 10 0
General Electric Company, switchboards	628 15 0
D.P. Battery Company, battery	836 1 0
Carrick and Ritchie, crane	95 10 0
Callender, cables	3,546 0 0
Carter, electric light buildings	4,174 0 0
Carter, engineering and road work	1,005 14 0

Messrs. Carter's tender was also accepted for the dust destructor building at £850.

London County Council.—The following tenders have been received in connection with the electric light installation for the Victoria-embankment and Westminster Bridge:

	Five lamps in series (enclosed arcs).	Ten lamps in series (open arcs).
St. Helens Cable Company	£5,016 5 0	£4 300 0 0
Siemens Bros. and Co.	5,762 12 6	4,947 17 6
British Insulated Wire Company	5,786 16 10	5,013 1 8
W. T. Henley's Telegraph Works Company	6,288 1 10	5,552 5 10
Western Electric Company	8,429 12 0	7,582 3 6

The St. Helens Cable Company's tender for open arcs has been accepted.

BUSINESS NOTES.

TRACTION.

Hampstead. — The circular letter from the Vestry of Paddington, referred to in our Holborn note, is before the General Purposes Committee of the Vestry.

Perth Police Commission.—The directors of the tramways company consider that a sum of at least £30,000 will be required to purchase the undertaking. The Commissioners are offering £20,000.

Hull.—Saturday last week was the busiest day the tramway department has experienced since it came into existence. The passengers totalled 123,946, and the aggregate receipts were £516 8s. 10d.

New Malden.—The District Council is making a canvass among the ratepayers with the object of obtaining their views on the tramways question. Electric trams seem to be preferred to any other system.

Edinburgh. — The Tramways Sub-Committee of the Town Council have agreed to recommend the acceptance of an estimate for the erection of the power station at Portobello. The total cost amounts to nearly £21,000.

Wycombe. — A scheme for the establishment of electric tramways was approved by the Town Council on Monday. The scheme provides for a service from the eastern to the western boundary of the borough, a distance of four miles.

Holborn.—The Board of Works have concurred in the resolution of the Vestry of Paddington protesting against further facilities being given to the London County Council for the laying down of tramways without the consent of the local authorities.

Glossop.—The Council have adopted a supplemental agreement with the Urban Electric Supply Company, Limited, with respect to proposed tramways in the borough. They have also decided to extend the tramways up Victoria-street and along Charlestown-road.

Electric Railways Co.—This Company has been registered with a capital of £75,000 in £1 shares, the object being to adopt an agreement with W. Shawe, to acquire any rights relating to railways, tramways, electric lighting or other electrical installations, the supply of electricity, etc.

Southport.—On Wednesday of last week the electric cars began running from Chapel-street, Eastbank-street, and London-street, continuing on their return journey up Houghton-street. Steps will be taken very shortly to raise the capital required for the proposed tramway from Southport to Lytham.

Stirling.—The annual general meeting of the shareholders of the Stirling and Bridge of Allan Tramways Company, Limited, was held at the company's office, Bridge of Allan, on Wednesday. Draft proposals between the Commissioners and the Tramway Company are being considered by a committee.

Coatbridge.—Mr. Murphy having failed to sign the agreement for the tramway he proposed to run in the burgh, authority has been given for the signing of an agreement with the Scottish House-to-House Electricity Company, Limited, who have works in the town, and who intend to apply to Parliament for powers.

Chester.—The Corporation have decided to acquire the undertaking of the tramways company for £18,000. The trams will be transformed into electric ones, and application is to be made for a special Act of Parliament authorising the Corporation to make the five extensions as recommended by the Tramways Committee.

Liverpool.—The resolutions in connection with the extension of the electric tramway system, which were blocked out last week, were carried at Wednesday's meeting of the City Council. This time the Irish members abandoned their hostile tactics, and joined with the other councillors in passing the resolutions. The Cork-street route was abandoned.

Wigan.—The Tramways Committee of the Corporation have decided to make application to the Urban District Councils of Standish and Aspull for sanction to construct tramways in their townships. They have also resolved to make enquiries from various towns as to the hours of labour and wages of tramway employés and as to the administration of tramway undertakings generally.

Bingley.—The District Council intend to apply for parliamentary powers for the manufacture and distribution of electricity, for an extensive scheme of street improvements, and for other powers. It has been suggested that the Council should combine with the Shipley District Council in a scheme for the extension of the Shipley tramways to the edge of the district and into Bingley.

Moss Side.—The chairman of the Highways and Lighting Committee (Mr. Box), with the clerk and surveyor, have been appointed to confer with the chairman of the Manchester Corporation Tramways Committee with regard to obtaining powers by the Council for the construction of additional tramlines in Withington-road and Greame-street, and for the continuation of the Princess-road lines to the Moss Side boundary.

Renfrew.—At the last meeting of the Town Council a letter was read from Mr. Turner, Greenock, informing the Council that application was intended to be made to the Secretary for Scotland for a provisional order for the construction of tramways within the burgh of Renfrew. The Tramways Committee was reappointed to confer with Paisley and Johnstone in promoting or assisting in promoting a measure for the building of tramways from Renfrew to Paisley.

Cardiff.—At the meeting of the Tramways Committee last Friday it was reported that Lord Tredegar declined to sell outright the land necessary for a railway siding for the electric generating station on the Newport-road site, but he offered the land at a rental of £25 A resolution was passed that the Corporation be asked to take over the equipment of the lines in their own behalf, and that the electric tramway engineer be allowed to appoint his own assistant at a salary commencing at £225, rising to a maximum of £300.

Birmingham.—The City Council have agreed that on and after Nov. 9 next a new committee be formed, to be called the Tramways Committee, to be nominated by the General Purposes Committee, under the standing orders, and that the powers and duties of the Council in reference to tramways be transferred from the Public Works Committee to the new committee. As an indication of the magnitude of the work the committee would have to do, it may be mentioned that the three companies in Birmingham take 55 million fares, and their gross takings are £300,000.

Brierfield.—At a recent meeting of the Urban District Council the Clerk reported an interview he and the chairman had had with the various authorities respecting the tramways. The only point was giving a joint notice to the Tramway Committee to purchase the entire length, and also to ask that before arbitration was entered upon what price they wanted and to state what they had to sell. It was also agreed that a notice should be sent asking to buy the tramway company's offices in Burnley, their depôt, and their rolling stock, and each of the other authorities would buy the lines in their own respective district.

Newport.—The report of the Lighting and Traffic Committee was discussed at the last meeting of the Corporation, and it was proposed as an amendment to the report that when the tramways were electrically equipped the Corporation should work the lines themselves, and not let them out to lessees. The amendment was defeated. In reply to the question of either the extension of the tramway system to the Alexandra Dockhead or the running of a service of 'buses, the Town Clerk said he would lay before the Traffic Committee at their next meeting the offer of a gentleman to put a motor 'bus on the road from the end of the tramline to the dockhead.

Salford.—The tramways engineer has reported that the rate of construction of the Great Clowes-street route is equivalent to one mile of single track in five weeks, and on the Pendleton route to

Digitized by Google

one mile of single track in nine weeks. The consideration of the report of the tramways engineer as to the cost of construction of tramways in other towns has been deferred until the actual cost of the works in Great Clowes-street is ascertained. On Wednesday the General Purposes Committee adopted the report of the Tramways Committee, and decided to recommend the Council to adopt the report and to confirm the arrangements with the Manchester Corporation.

Leigh.—The following recommendations of the Tramways Committee were approved at Tuesday's meeting of the Town Council: "That the town clerk, borough surveyor, and electrical engineer be instructed to report upon the advisability of the Corporation (1) constructing and working tramways; (2) constructing tramways and letting them on lease; (3) permitting a company to construct and work tramways within the borough. That the town clerk be instructed to request the South Lancashire Tramways Company, in pursuance of the South Lancashire Tramways Act, 1900, to widen St. Helens-road and King-street, the east and west sides of the north and south approaches to Leigh Bridge and Leigh-road."

Hanley.—At the last meeting of the Town Council a letter was read from the Potteries Electric Traction Company, in reply to a communication from the Council, stating that the company had building at the present time a large number of cars with a carrying capacity of 42 passengers, and that they were about to place another large order for cars of the some capacity, which it was hoped would be executed within the next four or five months, so that by the end of January it was anticipated the number of cars on the road would be nearly double what it is at present. It was decided to call the attention of the Potteries Electric Traction Company to the injustice in the increase of the fare from Miles Bank to Hanley Park from 1½d. to 2d.

Erdington.—The following resolution will come before the Urban District Council at their next meeting: "That in the opinion of this Council the time has arrived when it would be to the advantage of the inhabitants to have a system of tramways properly equipped on an up-to-date system, having regard to the great and increasing traffic on the main road of omnibuses and other passenger vehicles, and that it be an instruction to the General Purposes Committee to consider and report upon the desirability or otherwise of this Council applying for a private Bill giving them power to construct such tramway, it also being understood that the improvement works intended to be carried out in High-street be so designed as to arrange for the passage of such tramways."

Portsmouth.—The electric tramcars about to be ordered will be of the improved type, with the extended top deck and the reversed stairway, giving additional accommodation for six persons, at an extra cost of £40 per car on the contract price. The Tramway Committee's report on the reconstruction of the existing tramlines has been adopted, and they have been empowered to make variations where necessary. The committee hope to be able to submit estimates next December, and to commence the work of reconstructing the lines on the day on which they take them over—Jan. 1—so as to be able to run in time for the summer traffic. The cost of the double line is estimated at £16,000 per mile, that of the interlacing lines at £12,000 per mile, while a single line would cost £8,000 per mile. Taking the proposed lines at 20 miles of double track, this will mean an expenditure of £320,000.

Chelsea.—At the last meeting of the Vestry the surveyor submitted an application from Mr. A. J. Mules Brown, on behalf of Mr. G. Palmer Harding, for permission to erect wires on the lamp-posts in King's-road and Lower Sloane-street, from World's End towards Victoria, for the purpose of running electric cars. He explained that this was a new form of electric tramway which would do away with the necessity of laying rails or overhead wires in the streets. All that would be required would be to place connecting irons along the side of the road on a line with the kerb on poles. The cars would be for 24 passengers, and would weigh three tons. If the system could be worked practically it would solve the tramways questions, but there were many points to be considered, and he thought the matter might go to the Works Committee. The Vestry, however, decided to adjourn the consideration of the matter for a year.

New General Traction Co.—The half-yearly report of the directors states that the tramways at Norwich were opened on July 30, since when they had been working most successfully, producing results beyond the anticipations of the Board. The tramway in Coventry was finished and opened on Jan. 18, and a fair return on the investment is anticipated. The Philadelphia Suburban Traction Company's lines (about 20 miles), connecting Philadelphia with the cities of Chester and Media, are nearing completion, and a portion of the line has been in successful operation since July 1, and the directors feel satisfied with the future outlook. The Douglas Southern line has been in operation some time, and the Board expects the same dividend as was paid last year—viz., 6 per cent. on the preference shares. The directors expect that the company will be in receipt of dividends or interest from all the undertakings by the end of the current year.

Charing Cross-Hampstead Railway.—An account of an interview has appeared in the daily Press in which Mr. H. C. Davis, of New York, who is vice-chairman of the syndicate that has taken over the rights of constituting the Charing Cross, Euston, and Hampstead Railway, stated that the work will probably be commenced in February next, and it is hoped that it may be finished in two years. The power station for generating the electricity which will provide the motive power will be at Highgate-road. There will be two sets of lines, one starting from High-street, Hampstead, and running down Haverstock-hill, and the other from a station adjoining that of the Midland Railway at Kentish Town. They will unite at Camden Town High-street, and run to Euston Station. It will go under Tottenham Court-road to a station connected with the Central London Company's at Oxford-street, and thence to Charing Cross, thus linking together the Midland, London and North-Western, Central London, and South-Eastern Railways. The trains are to be worked on the "multiple unit" system, each carrying its own motor underneath, so that there will be no engines. The corridor cars will be glazed at the ends, so that passengers can see from one end of the train to the other. There will be an all-night service, and during the busy portions of the day trains will run every 2½ minutes. The journey from Hampstead to Charing Cross is expected to take 20 minutes. Mr. Davis said there would be no company floated here, the Yerkes Syndicate being prepared to find all the capital.

Strikes.—We learn that the difficulty with the Hull tramway men has been met by the Tramways Committee in a conciliatory spirit, with the result that now the men are working under improved conditions. The dispute was on the hours the men had to work, and the new arrangements consist of a 60-hour week, with one day in seven off for each man.—With regard to the Ashton tramwaymen's dispute, the *Manchester Guardian* says the Amalgamated Association of Tramwaymen and Hackney Carriage Employés has published its reply to the statement of the Oldham, Ashton, and Hyde Electric Tramway Company in reference to the strike of tramwaymen at Ashton. The reply, which is in the form of a letter to the Board of Trade, shows that 36 men in the company's service had worked from 4 to 54 hours' overtime during the three weeks preceding the strike, the aggregate overtime in that period having been 664 hours. Those men had gone on duty between four and five o'clock in the morning, and after they had finished their ordinary shift they had returned to work between 2.30 and five o'clock of the same day, and so worked the overtime referred to. The union contends that the company has no ground for reducing the staff, and alleges that men have been dismissed for joining the union, and that others have been threatened with dismissal in the event of their joining. In conclusion, the union say: "We feel convinced that if the Board would only allow us the opportunity of placing our side of the case before them, and producing evidence, a different aspect would be put upon it altogether, and it is for that purpose and in the interests of peace that we ask that some intervention should take place by the Board of Trade, and we bind ourselves to accept their decision."

Manchester.—In the last report of the directors of the Manchester Carriage and Tramways Company reference is made to the agreement which has been made with the Manchester Corporation as to the future working of the tramways by electricity within the city and within the districts of a large proportion of the surrounding local authorities. At the last Town Council meeting the following resolutions were adopted: "That this meeting hereby consents to the inclusion in the said Bill of provisions to confer further powers upon the Corporation in connection with their tramways undertaking by authorising the construction of additional tramways within the city, as follows: A double line of tramway commencing by a junction with the existing tramway in City-road, and passing thence along Medlock-street and Upper Medlock-street to the junction of the last-named street with Embden-street. A single line of tramway commencing at the junction of Upper Medlock-street and Embden-street, and passing along Embden-street in an easterly direction into and along Boundary-lane, and terminating by a junction with the existing tramway at the junction of Boundary-lane with Coupland-street. A single line of tramway commencing by a junction with the existing tramway in Greenheys-lane, and passing thence along Pigott-street into and along Renshaw-street, and terminating by a junction with the proposed tramway in Embden-street. A single line of tramway commencing by a junction with the existing tramway in Cheetham Hill-road, at the corner of Woodlands-street, and passing thence along Woodlands-street, Humphrey-street, Moss Bank, and Lansdowne-road, and terminating in such road at its junction with Oak-road. A single line of tramway commencing at the junction of Lansdowne-road and Oak-road, and passing thence along Oak-road into and along Crescent-road, and continuing along the last-named road in a westerly direction, and terminating by a junction with the existing tramway in Cheetham Hill-road. To substitute double lines for the existing single lines in Corporation-street and Cross-street."

Devonport.—We are informed that the probable date of the opening of the Devonport and district tramway lines for traffic will be about the end of December next. The Corporation have adopted a report of the Tramways Committee recommending that Mr. C. Chadwell, C.E., be instructed to prepare bills of quantities and specifications for the construction and equipment of St. Budeaux tramways, and to advertise for tenders; that the work be undertaken at the earliest possible moment, and that application be made for sanction to borrow the necessary moneys; and, further, that, having regard to the insurmountable delay in the construction of the St. Budeaux sewers and the rebuilding of Camel's Head Bridge, application be made for an extension of the period for the construction of the tramways. The minutes also contained a resolution that the committee would be willing to lease the line to the Devonport Tramways Company on the following terms: (1) The lines to be constructed by the Corporation at its own cost. (2) The lines when constructed to be leased to the company for a term of years. (3) The company to pay during the lease a yearly rent made up of the following items: (*a*) wayleave rent at the rate of £50 a mile; (*b*) the annual sum required for interest and sinking fund on the cost of construction; (*c*) one-third of the annual sum required for interest and sinking fund on the cost of rebuilding

Digitized by Google

Camel's Head Bridge. (4) The lease to contain such provisions as might be agreed upon or be reasonably required by the Corporation. (5) Following the precedent of the Croydon tramways, the lessees to be guaranteed in the due observance of the covenants and conditions of the lease by the British Electric Traction Company, Limited, entering into a bond with the Corporation in the sum of £15,000. (6) The company to repay to the Corporation the expenditure incurred by the latter in obtaining the powers for the St. Budeaux line, and also an agreed proportion of the cost of obtaining the powers for the new tramways authorised by the Devonport Corporation Act, 1900. (7) The tramways included in the lease to be worked by electrical energy, and that energy to be purchased from the Corporation.

LIGHTING AND GENERAL.

Stockton.—The electric lighting of the town is to be commenced next week.

Weston-super-Mare.—The electric lighting company have commenced to lay mains.

Stroud.—The resolution to apply for a provisional order, noted in our last issue, was agreed to on Wednesday.

Knottingley.—The question of electric lighting will again come before a meeting of the District Council shortly.

Dorchester.—Application is to be made to Parliament for a provisional order for lighting the borough with electricity.

Cuba Submarine Telegraph Co.—The directors recommend a dividend on the ordinary shares at the rate of 5 per cent. per annum.

Islington.—The London County Council have agreed to lend the Vestry £3,100 for electric light installations and street-lighting.

Blairgowrie.—The Police Commission have been conferring with Mr. Hawtayne with reference to the question of electric lighting.

Hampstead.—Fawley and Crediton roads are to be lighted by means of 16 incandescent electric lamps, at an estimated capital outlay of £98. 8s.

Indo-European Telegraph Co.—The directors have declared an interim dividend for the half-year ended June 30 at the rate of 5 per cent. per annum.

Maidstone.—An additional £4,000 is to be applied for in consequence of Mr. Preece's report on Messrs. Stevens and Barker's electric lighting scheme.

Newington.—The full financial report on the electric lighting scheme will probably be submitted by the end of the month. The accounts have been closed up.

Basingstoke.—The Council have engaged Mr. Reginald P. Wilson, of 66, Victoria-street, Westminster, to make a report in connection with the electric lighting scheme.

Burton.—During the past month the quantity of electric light sold in Board of Trade units was 9,790, showing an increase of 1,267 in the corresponding month of last year.

Canterbury.—The Council have decided to refer the matter of the assessment of the electric light works to arbitration, subject to an agreement being entered into by the Guardians.

Rochdale.—At the next meeting of the Corporation the General Purposes Committee will recommend the formation of two new bodies to be known as the Electric and Tramways Committees.

Grangemouth.—The Electric Lighting Committee have been empowered to employ a parliamentary agent for opposing the application of the North British Electric Supply Company.

Ellesmere.—At the next meeting of the Urban District Council, a letter from the Postmaster-General with reference to the proposed establishment of a Post Office telephone exchange in the town will be further discussed.

Grays.—The expenditure on the electric light scheme will come to £15,000. The accepted tenders appear in another column. A saving of £650 has been made on the original tenders for the building, and £350 on the cables.

Newport.—The Corporation have decided to apply to the Local Government Board for sanction to borrow £30 000 repayable within 25 years, required for electric lighting purposes. Of this sum £10,000 has already been spent.

Wealdstone.—The Council are allowing the Harrow Electric Light and Power Company to supply electric light to premises in the course of erection in that part of Station-road which has been transferred to their district from Harrow.

Barry.—A special meeting of the Council has been summoned with the object of "considering the desirability of passing a resolution that application be made to the Board of Trade for a provisional order under the Electric Lighting Acts."

Eastbourne.—The Town Council intend to apply to the Postmaster-General for a license, to expire in the year 1911, authorising the Council to provide a system of public telephonic communication within the borough of Eastbourne.

Friern Barnet.—At a recent special meeting of the District Council the question of applying to the Board of Trade for a provisional order for electric lighting was considered, and consideration of the whole matter was deferred till Oct. 27.

Rochester.—The Town Council are corresponding with the Chatham, Rochester, and District Electric Light Company with regard to the latter's offer to treat with the Corporation for the sale of that part of the undertaking which is within the city.

Hull.—We learn that the cause of the recent failure of the electric light lay in the mains, and was owing to a short-circuit, and not to a breakdown of dynamos, as was generally anticipated.

Launceston.—The differences which have existed for some little time past between the Launceston Town Council and the gas company have resulted in a proposal to light the town temporarily with oil, with the intention of eventually installing the electric light.

Ripon.—The City Council have decided to apply to the Board of Trade for a provisional order under the Electric Lighting Acts to authorise the Corporation to supply electrical energy in the city. The engineers appointed are Messrs. G. Harrison and Co., of Ripon.

Bermondsey.—Services have been recommenced at St. James's Church, Bermondsey. The exterior of the edifice has been repaired, the interior repainted, redecorated, and the electric light has been installed, the total cost, with other improvements, being about £2,000.

Appointments Vacant.—An assistant is required in the meter-testing department by the Edinburgh Corporation. There is also a switchboard attendant wanted by the Bradford Corporation. Full particulars of these vacancies appear in our advertisement columns.

Whitby.—The Urban District Council have accepted a number of contracts in connection with the installation of electric light. They have also decided to advertise for tenders at once for the loan of £9,000 towards the cost of the works, and for the remaining balances when required.

Luce-in-Makerfield.—Application is to be made to the Board of Trade on or before Dec. 21, 1900, for a provisional order under the Electric Lighting Acts, 1882 and 1888, to authorise the Urban District Council to supply electric energy for public and private purposes within their district.

Trowbridge.—Mr. D. Stevenson's report on the electricity supply has been adopted, and the Council have decided that the special meeting to consider the question of electricity supply be convened in such a form that it might deemed a statutory meeting in case the Council decide to apply for a provisional order.

Presentation.—On Friday, the 12th inst., the directors and London staff of the Brush Electrical Engineering Company presented their general manager, Mr. R. Percy Sellon, with a wedding gift, consisting of a silver bowl and inkstand, together with an illuminated album containing the autographs of the subscribers.

Vivograph Syndicate, Limited.—This Company has been registered with a capital of £80,000 in £1 shares, the objects being to carry on in all their branches the businesses of electricians, electrical, mechanical, metallurgical, and general engineers, and contractors for the supply of electrical and other power.

Poplar Lighting.—With respect to the article on the opening of the Poplar electricity works, which appeared in our last week's issue, we are informed that the lamps supplied are all of the patent Brockie-Pell type, and were made by the Brockie-Pell Arc Lamp Company, they being the sole owners and manufacturers of this lamp.

Rotherhithe.—At the Vestry meeting on Tuesday a letter was read from the County of London and Brush Provincial Electric Lighting Company, Limited, relative to the notice served by that company in June last of their intention to apply for a provisional order in respect to this parish, asking for the consent of the Vestry in the matter.

Brighton.—At the Council meeting on Wednesday afternoon a report was submitted recommending that application be made for a loan of £56,500 for electric lighting. Machinery and plant will absorb about £26,500 of the total sum, and mains and house services about £28,500. The remaining £1,500 will be for contingencies.

Book Received.—We are in receipt of an exceedingly well illustrated and exhaustive work entitled "Flame Electricity and the Camera; Man's Progress from the First Kindling of Fire to the Wireless Telegraph and the Photography of Colour," by George Iles, and published by Grant Richards, London, on Tuesday, Oct. 16.

Oldham.—The Town Council propose to apply to the Local Government Board for sanction to borrow £157,000 for the purpose of erecting at Greenhill a station for the supply of electric energy, both for lighting and power and for tramway purposes, together with the necessary engines, boilers, dynamos, workshops, stores, and all accessories.

Sudbury.—The Town Council have confirmed their intention noticed in our last issue, and have resolved to make application to the Local Government Board for borrowing powers for the two sums of £4,523 and £15,536 required, and that intimation be given that at the same time an application would be made for a loan for electric lighting works.

Wakefield.—During the present week Messrs. Fowler, of Leeds, have placed two transformers in the electrical sub station at the top of Westgate, as part of the extra plant necessary for enabling the Corporation to cope with the extraordinary load. The capacity of the new transformers will admit the simultaneous lighting of about 3,000 additional lamps.

Gloucester.—At a special meeting in committee of the Gloucester City Council on Wednesday it was decided to recommend the Corporation to entertain a proposal for purchasing and working the local tramways. The company owning these lines at present have applied for powers to lay down new and extended lines, and to employ electricity as the motive power.

Digitized by Google

"Britannic the Second."—The Thames Electric and Steam Launch Works, of Strand-on-the-Green, Chiswick, recently launched a neat little steam-launch of the above name, which they have constructed for H. Artrop, Esq. The fittings of the boat throughout are of teak, and electricity is used to light the cabins, and also for the bells required on board.

Heywood.—The Council have already applications for 2,700 8 c.p. lamps out of the 4,000, or about two-thirds of the power which they are providing for. The charge for current has been fixed at 6d. per unit, inclusive of free wiring. Application is to be made for power to borrow an additional £2,000 for electric lighting works. This will make a total of £17,000 obtained.

Stirling.—The electrical engineer is preparing a report on the cost of erecting 10 lamps in the Craigs district. A proposal by the engineer to charge less for the electric light to basement premises lit during the day, and recommending that the rate be 4d. per unit, with a minimum charge of £1 per quarter, the consumer paying for the special meter required, has been approved.

Penzance.—Out of the 28 applications received for the appointment of an electrical engineer to report on electric lighting the following have been selected: Lacy, Clirehugh, and Sillar, F. J. Warden-Stevens, James C. Shoolbred, W. H. Trentham, Reginald P. Wilson, Thomas L. Miller, Medhurst and Lloyd, Robert Hammond. The appointment will probably be made on Monday next.

Norton.—The Norton (Malton) Urban District Council on Monday sealed an agreement with the Northern Counties Electricity Supply Association, authorising the latter to apply for a provisional order to light the district by electricity. The company undertakes to do the public lighting at 30 per cent. less than the present cost of gas, and to charge private consumers not more than 7d. per unit.

Rome.—The Italian Government have established telephone wires along the Italian Alps with the object of connecting Rome with Paris. Owing to the enormous difficulties which have been encountered, it has taken seven months to complete the work. The French Government are now making preparations their side of the Alps, and it will take some months yet before the line to Paris is completed.

Catalogue.—We have received from Messrs. J. P. Hall and Co., of Oldham, a copy of their catalogue of electrical machines. The catalogue is neatly bound, and the inside matter is very plainly set forth. Various machines are illustrated, and measurements, speeds, powers, and quantities connected with the dynamos and motors supplied by the firm are given. The firm has, we notice, obtained a silver medal at the Paris Exhibition this year.

Colwyn Bay.—Mr. Leigh (the engineer) has submitted a report upon the extension of cables necessary for the purpose of connecting Pwllycrochan Hotel and the Penrhos College, and the probable cost thereof, and the Urban District Council have deferred its further consideration for a month. The engineer will in the meantime furnish the committee with an estimate of the cost of the extra plant required to meet immediate wants.

Macclesfield.—A committee, consisting of the Mayor, Aldermen Pickford, Eaton, Fountain, and Savage, and Councillors Cameron, Shaw, Ibeson, and Cross, have been appointed to confer with the town clerk and take all steps necessary for the procuration of a provisional order to establish an electrical installation for the borough. The question of the appointment of an electrical expert has been left over until after the elections on Nov. 9.

Chiswick.—The work of laying the cables in connection with the electric light in this parish is being proceeded with rapidly, and the erection of the generating station is in progress. The company will probably be in a position to supply the light from their own station by the latter end of the year. We understand that, as a temporary measure, arrangements have been made with the Hammersmith Electric Light Company for the supply.

Fire Alarms.—On Thursday evening last week the City brigades were turned out in strong force by a "call" from a warehouse in Australian-avenue, Bishopsgate-street, which is fitted with a new fire-alarm apparatus. This arrangement is supposed to get into working order through heat, which at a certain temperature acts upon mercury, and by contact with electricity rings the fire alarm. The bells were still ringing when the different fire brigades arrived, but there was no fire.

London Gazette.—A supplementary dividend of ½d. per £ has been declared in the estate of A. G. Inrig, 46, Whitepost-lane, Victoria Park, London, payable on Oct. 23 at the office of the trustee, E. H. Hawkins, Wholesale Traders' Association, 3, Barbican, E.C.—The Light Railway Commissioners have submitted to the Board of Trade an order made by them for the construction of light railways in the parish and urban district of Rhyl, in the county of Flint.

Welsbach Meeting.—We note comments in the evening papers complaining that reporters in the first instance were refused admittance at the Wednesday's meeting of the preference shareholders of the Welsbach Company, and that after the point had been conceded "copy" was conspicuous by its absence. The subsequent meeting did not produce a quorum, some £950,000 stock being represented, whereas a representation to the amount of a million was necessary under the articles.

The Andrews Joint-Box.—With respect to the Andrews and Glass joint-box, described in our last issue, we are informed by the makers, Messrs. Cowans, of Salford, that no special skill is necessary on the part of the man using this joint-box. In a service joint recently made by a labourer, though his time fell short of the record referred to in our article by seven minutes, the result was a joint with which no fault could be found. Some instruction is, of course, necessary in the first instance, and Messrs. Cowans arrange to send a man to make a few sample joints in any place where the box is being given a trial.

Stock Exchange.—The Stock Exchange Committee have appointed Oct. 31 as a special settling day for United River Plate Telephone Company's further issue of 23,361 5 per cent. cumulative preference shares of £5 each, £3. 10s. paid, Nos. 16,640 to 40,000. The committee have also ordered the said securities to be quoted in the official list. The committee have also been asked to appoint a special settling day in Willans and Robinson's further issue of 10,000 ordinary shares of £5 each, Nos. 90,001 to 100,000, and 10,000 6 per cent. cumulative preference shares of £5 each, Nos. 70,001 to 80,000, and to allow the following securities to be quoted in the official list: Willans and Robinson's further issue of 10,000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 60,001 to 70,000.

Papristeel Conduits.—We have received from the General Electric Company a circular which they have just issued regarding their "papristeel" conduit. This is an improved form of the firm's well-known "union" steel tubing, in so far that to the mechanical advantages of this latter are added good insulation and proof against damp. This tube can be supplied with screwed fittings if necessary, and is standardised to fit their "union" system of accessories. This will be found of great advantage in the installing of the tube and the cost of the system, combining as it does the qualities of the various mechanical and insulating conduits is exceedingly low. The conduit is made with external diameters ranging from ½in. to 1½in. The insulating material consists of paper tube, this being drawn over with the union steel conduit.

Hornsey.—The District Council have decided to at once proceed with the installation of the electric light in a portion of the district under their charge, and last Friday Colonel Luard sat at the Council offices, Highgate, to take evidence with reference to the application of the Council to the Local Government Board for sanction to borrow £73,500 for the purposes of the scheme. The scheme is that of Mr. Robert Hammond, and the buildings are to be erected from the plans of Mr. E. J. Lovegrove, the Council's engineer. The generating station will adjoin the Great Northern Railway at Hornsey, and be on the same site as the new public baths, the spare heat from the furnaces being used in the baths. It is intended to replace 155 gas lamps by 94 arc lamps, and the estimated revenue at a lower price than gas at 3s. per 1,000ft. is sufficient to leave a margin of £1,764, after paying all charges.

Fitting Lord Ellesmere's House.—A number of leading manufacturers in England and France were recently invited to submit designs for electric fittings for Bridgewater House, London, the town residence of the Earl of Ellesmere. Considerably over 100 designs were sent in, and those submitted by Messrs. Dennison, Berlyn, Sillem, and Co., Great Portland-street, W., were selected, and the order has been placed with that firm. A brief description of these fittings should be interesting. Thus massive circular dishes of elaborately cut glass, 24in. in diameter, surmounted by finely designed metal coronas form the principal part of each electrolier. These coronas of wrought and chased metal are in the style of the Italian Renaissance, in keeping with the decoration of Bridgewater House. The electroliers consist of handsome coronas with six crystal pendants surrounding the larger central cut-glass dish, and carrying 45 lights in all, these coronas being supported by chains and rings from metal crowns at the ceiling above. The state rooms alone will take 16 of these electroliers, and the scheme is throughout of the most costly description, and in its way is quite unique.

London County Council.—At Tuesday's meeting of the Council the Highways Committee recommended the Council to make application in the next session of Parliament for powers (1) for the construction of tramways for electrical traction between the present terminus of the London County Council tramways at High street, Tooting, to the county boundary at Waterfall Bridge; (2) to acquire the St. Matthew's girls' school premises adjoining the Camberwell tramway depôt for the establishment of a generating station for the London County Council tramways. The committee also recommended that the resolution of the Council of Aug. 1, 1899, with reference to the application to the Board of Trade for a license under the London Tramways Act, 1888, to authorise the experimental use of mechanical traction on the tramways between Westminster Bridge and Tooting, be not further acted upon. This action is taken because powers have now been obtained by the London Council Tramways (Electrical Power) Act, 1900, for the reconstruction for electrical traction of the whole of the Council's tramways, including the portion from Westminster Bridge to Tooting. It was further recommended that no further action be taken upon the resolutions of the Council of March 27 and May 15, 1900, respectively, with regard to the institution of proceedings against the London Electric Supply Corporation in respect of the company's failure to maintain a proper supply of electrical energy in the areas included in the company's orders of 1889 and 1890. A very large number of applications to lay mains, etc., were sanctioned under the usual conditions, also an application from the General Post Office for permission to lay (*a*) two 3in. pipes for telephone wires from the south-west corner of Temple-avenue into the Victoria-embankment subway, and (*b*) one 3in. pipe from the south-west corner of Carmelite-street into the subway.

Portsmouth.—The Postmaster-General has granted the application of the Town Council for a license to establish and work for 25 years a municipal telephone exchange in that town. A special

Digitized by Google

committee is to be appointed to take charge of the undertaking, and the co-operation of local authorities in contiguous townships has been secured. The Fareham Urban District Council have decided to support the proposal on condition that they retained control of their roads.

Sevenoaks.—At the last meeting of the Urban District Council the report of the sub-committee appointed to interview the Electrical Power Distribution Company, Limited, on the question of supplying Sevenoaks with the electric light was presented, and it was stated that the company had met them with every good spirit, which pointed to the probability of the electric light being provided for Sevenoaks on most satisfactory terms, and at great convenience to the district.

Perth.—At a recent meeting of the Electric Lighting Committee, a letter was read from Mr. Hawtayne stating that the lamp columns ordered for Atholl-street have the lamps supported centrally, and that they would not be suitable for the lighting from the side of the street. The Commissioners therefore decided to abide by their first resolution and retain the lamp-posts in the middle of the street. The distributing mains will be laid along the south side of the street, and a cable run across to each lamp therefrom.

Articled Pupils.—At a recent meeting of the Sheffield Town Council attention was called to a resolution to receive a youth as an articled pupil at the electric supply department. It was taken for granted that the head of a department is not to receive any premium. At the same time it was argued that this was unfair to a head official, for why should he give special attention to a youth without recompense? Ultimately the Council accepted the youth, as suggested by the committee, and referred the general question to the Finance Committee.

Ilford.—At the last meeting of the Urban District Council the Clerk read a letter from the Local Government Board with reference to the Council's suggestion to contribute £350 to the cost of placing the telegraph wires underground. They stated that they knew of no authority under which such payment could be made, and therefore could not authorise such payment. It was resolved that a deputation consisting of the chairman, vice-chairman, and the clerk should attend on the Local Government Board to explain the matter.

Brighton.—It has been decided to include in the Bill to be promoted by the Corporation in the next session power to the Corporation to purchase and hire out to consumers or wiring contractors electric motors, cooking, heating, and ventilating apparatus. Feeder No. 11 is to be extended to the south side of Grand Junction-parade at an estimated cost of £2,500. The engineer has been instructed to report upon a proposal that the public street lamps in the upper portion of New England-road and the lower portion of Chatham-place should be lighted by electricity.

Morecambe.—At the last meeting of the Urban District Council a letter was read from the Technical Instruction Committee, asking that, on the score of health, electricity might be used as an illuminant instead of gas. The excessive heat caused by the gas had caused many headaches. It was decided to refer the matter to the Plans Committee. During the discussion it was suggested that in the meantime estimates might be obtained from tradesmen as to the cost of substituting electric light, and it was stated that a minute had been formerly passed authorising the adoption of the electric light.

Glasgow.—On Saturday the Port Dundas electricity works were thrown open for the inspection of the electrical engineers and others in the city interested in the development of the application of electricity. The visitors, about 700 in number, were received by Bailie Maclay, convener of the Electricity Committee; Bailie Willock, convener of the Works Committee; and by Mr. Chamen, chief engineer. We learn that the opening of the station, which was described in our issue of Sept. 21, has excited such great interest in electrical circles far outside of Glasgow, as well as amongst the general body of ratepayers, that the committee will probably have the works open again for inspection by the general public.

Walsall.—The total number of consumers supplied on Sept. 30 last was 165. The total units generated at the station during the month of September was 29,043. The total units from the transformers was 21,564. The Local Government Board have approved that the land formerly part of the site of the Wolverhampton-street gasworks be appropriated for the electric lighting undertaking. The Board have also sanctioned loans of £6,320 and £3,150 out of the proposed loan of £15,000 for the purpose of the electric lighting undertaking, and they have asked for a detailed estimate of the cost of the proposed works in relation to the application for a loan of £5,678 for the extension of the electric lighting mains to Bescot.

Smethwick.—The Council have decided to consult Mr. J. G. Aldridge, electrical engineer, with regard to their negotiations with the British Electric Traction Company. We understand that a somewhat more favourable basis of negotiations has been arrived at, according to which the Council would have the power to take over the concern in seven or fourteen years after the expiration of the present lease, the British Electric Traction Company paying all expenses of management, and while agreeing to hand over to the Council a percentage of the gross receipts, will also undertake to supply electricity for lighting and other purposes to private consumers at the same rates which are current in neighbouring districts.

Hove.—It has been decided that a committee, to consist of seven members, be appointed to carry out the following duties—viz.: to superintend the lighting of the public streets; to fix and determine the situation of all lamps within the borough; to have charge of all matters arising out of the electric lighting orders in force within the borough, or any deed of transfer, contract, or deed made thereunder, particularly as to carrying out the electric lighting order for Aldrington; and generally to take cognisance of electric lighting within the borough, and also to have the special control of any officer appointed particularly for electric lighting purposes; and that the duties of the Works and Improvements Committee be varied accordingly.

Sheffield.—The question of the cheap supply of electricity was discussed at the Town Council meeting last week, and it was suggested that the Electric Light Committee should make full enquiry whether the supply could be obtained at the pit mouth or elsewhere. The consumption of electricity would increase by leaps and bounds in the near future, and the Council should know which was the cheapest source of supply. The committee propose to recommend the Council to establish a new generating station for the development of electricity on a large scale, and the whole question will then be discussed. The question of the pit mouth is to be considered by the engineer. It appears that the water power of the city cannot well be utilised for the generation of electricity.

City of London.—A scheme was introduced at the Court of Common Council on Thursday week for the testing in future of all electric meters within the City under the direction of the electric inspector at the expense of the City of London Electric Lighting Company and the Charing Cross and Strand Electricity Supply Corporation, each company to contribute, in addition to the other expenses, £200 per annum to the Corporation in respect of the electrical inspector's salary. Under those circumstances, it was proposed that the inspector's salary should be increased from £350 to £500 per annum. Under the scheme the Corporation would be relieved in future of all expenses connected with the appointment, those expenses at present amounting to £350 per annum. Finally, consideration of the matter was adjourned.

Airdrie.—The Scottish House-to-House Electricity Company, Limited, have acquired the interest of the New General Traction Company, Limited, in the Airdrie tramway scheme, and they are arranging to obtain similar powers for the adjoining burgh of Coatbridge, which they at present light with electricity. Airdrie Town Council having previously acquired a provisional order for the electric lighting of the town, a conference was held on the 12th inst. as to the House-to-House Company acquiring that order, and lighting Airdrie from their works at Coatbridge as well as running the tramway. A resolution was carried recommending the Town Council to dispose of its provisional order to this company upon terms indicated by the company's representative, but which have not as yet been definitely concluded.

Salford.—A private conference of members of local authorities was held on the 10th inst. in the town hall to consider the question of providing or securing an improved telephonic service within the National Telephone Company's district, of which Manchester is the centre. The Mayor of Salford presided. Other members of the Corporation and about 30 representatives of neighbouring authorities, including Eccles, Bowdon, Failsworth, Prestwich, Levenshulme, Swinton and Pendlebury, Whitefield, etc., were present. A resolution was carried unanimously, "That a committee be now appointed to consider the question of providing better facilities for telephonic communication, and to report their recommendations on the matter to a future meeting." It was decided that the committee should consist of one representative from each of the local authorities invited to the conference.

Harrogate.—The Corporation's electric light installation was established in April, 1897 and the total loans sanctioned up to the present time amount to £68 724. During the third year 365,404 units have been sold, as against 201,363 in the second, bringing in a total revenue of £6,400, an increase of £1,732. The net profit for the past year, after the payment of all charges, is £777. The previous year showed a deficit of £729, which has now been discharged. There is an increased demand for the light, and the Corporation have reduced the tariff. The Council have decided to apply to the Local Government Board for sanction to a further loan of £10,000 for a new boiler house and generating plant equal to the supply of 10 000 additional lamps. An additional trunk main from the works to the town has also been arranged for. This immediate extension, however, forms only a portion of the complete extensions contemplated. The remaining portion of the projected works is estimated to cost £40,000.

Londonderry.—Mr. Macrory, electrical engineer, has prepared a report on supplying the shipyard with electricity for lighting and power purposes. He stated he had obtained from the managing director of the shipyard particulars of their requirements and made his calculations as to the extra plant, engines, conduits, cables, etc., necessary, of which details were given in the report. This projected scheme would be so wrought out as to serve in its district as a part of a larger extension for private lighting and power when such should be deemed necessary. He also gave detailed estimate of revenue and expenditure. The whole cost of the project to supply the shipyard with electric lighting and power on the basis of the requirements indicated would cost for everything £5,300. This money could be borrowed. To repay the borrowed money with interest, as well as to pay for the maintenance of the machinery in good order and the ordinary working expenses, a sum of £1 421 per year was wanted. It was estimated that the shipyard would pay to the Corporation £1,580 annually, thus leaving a net profit of about £160 a year.

Derby.—The Town Council have applied for a loan of £35,000, this being the estimated amount of capital expenditure on electric lighting account for the next two years. During the discussion

Digitized by Google

on the subject, it was stated that the net result of the year's trading was that the committee had paid not only the ordinary interest upon the capital, which amounted to £105 000, but they had also repaid £2,507 of loans borrowed, and, in addition, they had a small margin of £113 to the good. Of the £35,000, £8,650 was required for a new engine, and it was necessary to order the engine within a short time, as manufacturers could not put forward the work under something like two years of notice. In the first eight months of this year there had been an increase of 9,000 in the number of lamps, as compared with an increase of 7,800 last year. This demand was still increasing, and there were more demands in the office now for electric lighting than at any previous time. Hence the desirability of looking ahead, and providing themselves with machinery which would certainly be wanted within the time he had stated. A new chimney would be required, and the extension of the mains would cost £7,500.

Motor-Generators.—The Metropolitan Company are gradually converting their old single-phase system into a continuous-current system, the generating station being situated at Willesden, from which the current will be sent to various sub-stations in the company's area. The contract for the electrical equipment of the new Manchester-square sub-station has been placed with Messrs. Witting Bros., Limited, 49, Cannon-street, E.C., and comprises about 9,000 h.p. of heavy machinery. There will be six synchronous polyphase motor-generators of 500 kw., each machine consisting of a 900 b.h.p. motor direct coupled with a multipolar continuous-current generator of 500 kw. In addition to the six large sets, there will be three auxiliary motor-generators of 70 kw. to 80 kw. for starting and exciting the large machines, and for helping with the day load. The two phase current generated by the Westinghouse alternators in the power station at Willesden is stepped up from 500 to 10,000 volts per phase, then sent over about 5½ miles of cable to Manchester square, where it is transformed down to 1,000 volts per phase for the motor generators. The sub station equipment will be of a highly interesting nature, as special arrangements are necessary in such cases to ensure the perfect parallel working of the large synchronous motors at all loads; the problem of feeding such large synchronous motors, placed at the end of a long transmission line, possessing both inductance and capacity, being by no means an easy one when the power is supplied from a steam-driven station, as is the case in question.

St George (Hanover square).—The Vestry met specially on Thursday week to consider the question of the lighting of the parish by electricity. At the outset of the meeting a letter was read from the Gaslight and Coke Company, asking the Vestry to postpone for a short time their final decision on the matter, as at the next meeting of the company they would have under consideration a more comprehensive scheme for the better gas lighting of the parish at much less cost than the scheme of the electric lighting company, which they would submit to the Vestry. The recommendation of the committee was that the agreement between the Vestry and the Westminster Electric Supply Corporation, Limited, be approved and adopted, and that the seal of the Vestry be affixed to the agreement with the corporation. The agreement, which was adopted and sealed by the Vestry, provided among other conditions that the company should commence the works immediately on the completion of the agreement, and should complete the 600 arc lamps by June 30, 1902. Lighting according to schedule was to be at the rate of £32 per annum for each 750 watt arc lamp, £22 for each 500-watt arc lamp, £4 per annum for each 120 watt incandescent lamp, and £3 for each 60 watt incandescent lamp, these rates to be subject to a cumulative rebate of one half per centum per annum for each year after the first full year during which any lamp has been used. One of the most important clauses, and one which has been the subject of much debate, runs as follows: "In the tenth and twentieth year after the date of this agreement the Vestry shall be entitled to refer to an arbitrator, to be appointed by the president of the Institute of Civil Engineers, the question whether the payment per lamp per annum fixed by this agreement should be varied in consequence of the adoption by the company of any improvement or method which has resulted in a substantial alteration in the cost of lighting the streets by electricity, and it shall be in the discretion of the arbitrator to vary such payment in any manner he may think fit; but no variation shall be made which shall cause the future profits of the company to be less than they were immediately prior to the adoption of such improvement or method. If, however, any increase in profit shall result to the company from the adoption of such improvement or method, such increase of profit may be apportioned between the company and the Vestry in such a manner as the arbitrator shall think fit to award, provided that such apportionment shall not apply to any profits which shall have accrued to the company prior to the date of such award."

New Issue.—The City of London Electric Lighting Company, Limited, this week made an issue of £200,000 4½ per cent. second debenture stock, at £100 per cent., redeemable at par in either of the following events—viz.: (1) at the option of the company at any time after Dec. 31, 1910, on six months' notice; (2) in the event of a winding-up or of the security from any other reason becoming enforceable before Dec. 31, 1910. The stock forms part of the additional amount of £400,000 which the directors were authorised to borrow by a resolution passed at an extraordinary general meeting of the company held on July 11, 1900. It will bear interest at the rate of £4. 10*s.* per cent. per annum, and will be redeemable, on six months' notice, at the company's option at any time after Dec. 31, 1910, at £100 per cent. It will rank *pari passu* as a second charge by way of floating security upon the undertaking and business of the company and its property present and future (excluding its uncalled capital for the time being), subject only to the first charge to secure the £400,000 5 per cent. debenture stock already issued by the company, and the premium of £100,000, payable on redemption in respect thereof. In the event of a sale to the local authority, the net proceeds of sale will be applied (subject to the redemption of the £400,000 5 per cent. first debenture stock at £125 per cent.) to the redemption of the second debenture stock at £100 per cent., and in the event of a winding-up, or of the security from any other reason becoming enforceable before Dec. 31, 1910, the stock will be redeemed at a like rate. Power is reserved to create further second debenture stock, ranking *pari passu* with the present issue, to an amount not exceeding the sum of £200,000. The present issue of debenture stock is made in order to provide for the large capital expenditure necessary to enable the company to cope with the constantly growing number of lamps and motors to be supplied. From the prospectus we note that on Dec. 31, 1899, the number of customers was 8 738, while during the present year, up to Oct. 3, further applications to the extent of 57,918 lamps have been registered, raising the total at that date to 508,856 8-c.p. lamps, of which 487,540 were then connected, representing 9,323 customers. This shows an average weekly increase of applications for 1,466 lamps during 1900. The gross revenue of the company has been as follows: £68 863. 19*s.* 3d. for the year ended Dec. 31, 1894, and £187,253. 16*s.* 7d. for the year ended Dec. 31, 1899. This represents a net revenue remaining after the payment of interest on first debenture stock, and the deduction of the actual cost of repairs and renewals of plant, etc., of £48,870. 18*s.* 11d. The recent revision of the rates charged to customers (which confers a distinct benefit on the long-hour consumer), and the large number of additional lamps supplied, will, it is estimated, increase the gross revenue of the company for the year 1900 to about £225,000. The annual interest on the present issue of debenture stock will amount to £9 000 only. The assets of the company are stated at £1,254,572. 16*s.* after deduction of the first 5 per cent. debenture stock inclusive of premium payable on redemption.

Ayr.—The Corporation have received a long report on the proposed change of electric lighting system by Mr. W. A. Chamen, electrical engineer of the Glasgow Corporation. The following are the principal portions of the report, for which we are indebted to the *Ayrshire Observer*: "With regard to the main question of the change of system of supply from high-tension to low-tension continuous current with a three-wire system, I am entirely of opinion that this should be done, and at once. You are in an exceptional position, having an opportunity of getting rid of one of your existing engines and alternators, for which you will receive an allowance of about £1,500 in consideration of your ordering from the makers, Messrs. Siemens Bros. and Co., an engine and dynamo, or alternator, whichever you may choose in place thereof. There is no doubt in my mind that you should decide immediately to make this new engine and dynamo of the continuous-current type, and as nearly as possible like the two which you have already ordered for the tramways plant so as to be interchangeable with them either for lighting or tramway supply. If you do this you will be in a position of having one continuous-current set of plant available for electric lighting, one ditto ditto for tramway supply, and a third set available as a reserve for either of these purposes. There can be no doubt that you will gain greatly by giving a supply of continuous current in the central area instead of alternating current. It will enable you to work with greater economy and to use accumulators, which will be of assistance for times of light load, and it will give your consumers the great benefit of being able to use electric motors without any of the troublesome conditions which arise when using motors with an alternating-current supply. You will probably find it convenient and economical as time goes on to increase your low-tension continuous-current plant, reserving the high-tension plant for the outlying districts, some of which, at any rate, are rather too far off to be satisfactorily reached with a low-tension supply. As regards the extent to which the low-tension supply should be at first adopted, I would say that Mr. Fuller's proposal to deal with High-street, Alloway street, Burns Statue-square, Kyle street, Newmarket-street, and Sandgate-street, together with the various offshoots from these streets, seems quite the right thing to do for a start; but there is no doubt that you will find it convenient to increase the radius later to anything between one and two miles. The principle upon which I would recommend you to proceed is to make all further new plant which you may require to meet increased demand from time to time of the continuous current type, and to utilise the alternating plant you already have for the purpose of supplying only the more distant consumers, who will presumably also increase in due course. In this way, when you increase your continuous-current plant, you will at the same time increase the area which you will supply with continuous current, while you will be retaining your existing alternating-current plant in economical use, and be saved the loss you would be likely to incur if you were to attempt to dispose of it now." The Corporation have agreed to adopt the change of system recommended by the report, and to order the low-tension engines from Messrs. Siemens, and have also instructed Mr. Fuller to proceed to Messrs. Siemens and arrange as to the plant and the price to be paid therefor, and authorising him to close matters unless Messrs. Siemens want any material change made on the existing proposal.

Nantwich. — The following report is before the General Purposes Committee of the Urban District Council, which has been compiled by the Electric Lighting Sub-Committee. The document, according to the *Nantwich Guardian*, described the

Digitized by Google

systems at work in the following towns visited—namely, Blackpool, St. Annes, Llanrwst, Chester, and Darwen. Though the works visited, the report continued, were nearly all considerably larger than any works that might be constructed at Nantwich, the principles involved in small works were the same as in large ones. The principal matters that would have to be considered in connection with the proposed works at Nantwich were: the site for a generating station, the best system to be employed, the extent of the area of supply, the capacity of the generating plant, the price to be charged for current, the question of free wiring, and lastly, the question of employing an expert to advise. With regard to the site of the generating station, where coal was the fuel used, it was a great advantage if a site could be obtained near a railway station or canal, in order that the cost of carting might be saved. A good supply of water should also be obtainable, to allow condensing operations to be carried out cheaply, without a large quantity of auxiliary machinery. The works should be central, and not cause a nuisance to adjoining property, and there should be means of getting in heavy goods. With regard to the works being a nuisance to adjoining property, it was clearly demonstrated at Darwen that those, even in conjunction with a refuse destructor, if properly carried out, could be placed almost in the centre of the town without any nuisance arising. The site in Wall-lane was central, and, if adopted, water for condensing purposes could probably be obtained from the river. With regard to the question of fuel, the sub-committee were of the opinion that it was advisable to construct a refuse destructor in connection with the electric light works, from which the greater portion of the steam required could be raised, and at the same time a great deal of carting, both of coal and refuse, saved; at present the latter had frequently to be carted long distances to a suitable tip. The quantity of refuse available was, they understood, about 15 to 16 tons per day. With a Meldrum destructor and a Lancashire boiler, no doubt 112 i.h.p. could be obtained, which would probably be found sufficient to supply the whole of the demand for some little time. The estimated cost of a destructor of the size required, with boiler, chimneys, and buildings complete, would be about £2,000. About half of this, or £1,000, would represent the actual extra cost of the destructor, as boiler, chimney, and buildings would be required in any case. A duplicate boiler should also be provided and arranged for hand-firing with coal. This could then be used as a reservoir for steam, and thus assist in steadying the steam pressure, which was apt to vary considerably when raised by destructors. With regard to the best system to adopt, they recommended the three-wire 500-volt (with continuous current) system, supplied to consumers at 250 volts; and the best method of laying the conductors was in wooden troughing filled with pitch. As to the extent of the area of supply, this, within reasonable limits, should be as large as possible, so as to get the greatest number of street lamps of the mains. It was also found that consumers, as a rule, would not join till they saw the cable actually laid. The generating plant should be sufficient for immediate requirements, allowing some margin for contingencies. In small works it was out of the question to have any of the plant idle, but ample provision for additional machinery should be made in the buildings. It was essential in small schemes like theirs that the works should be carried out with the utmost economy consistent with efficiency. There were two principal methods of charging for electricity—namely, the uniform price and the long-hour consumer rate. Both were extensively adopted. The uniform rate was the simplest, though the long-hour consumer rate was the most favourable to large consumers, who had to be encouraged. They thought that the uniform rate would be found the best—at all events, to begin with. As to free wiring, they found that this was not general, and where practised was being discontinued. With regard to the employment of an expert to advise, there appeared to be two methods—viz.: first, the appointment of a competent resident engineer, who had been employed in similar works, to prepare plans and carry out the works; second, the employment of an expert as consulting engineer to take the direction and be responsible for the scheme, with a resident manager to look after the technical and commercial part of the undertaking. They were not in a position to say definitely which of these methods was the better until the cost of each had been ascertained.

PROVISIONAL PATENTS, 1900.

OCTOBER 8.

17811. An improved electric arc lamp. Frederick Hungerford Bowman and Thomas Archer Rose, 9, Adam-street, Strand, London.

17829. An improved device for measuring upward pressures, and particularly for enabling the trolley arms of electric tramcars and vehicles being set to exert a certain upward pressure on the wire. Joseph Wilkinson, 8, Quality-court, Chancery-lane, London.

17846. Improvements in telephones. Charles Shore and Charles Heap, 6, Bank-street, Manchester. (Complete specification.)

17865. Improvements in the operating mechanism of electric controllers. Thorsten von Zweigbergk, Clun House, Surrey-street, Strand, London.

OCTOBER 9.

17904. Improvements in or relating to electric meters. John Ellis, 111, Hatton-garden, London.

17916. Improvements in dynamo-electric machines. Matthew William Wallbank Mackie and Egerton John Glyn, 77, Turnmill-street, London.

17917. Improvements in means and apparatus for relaying electrical currents. Hartwell William Webb, 9, Ellison-terrace, Streatham, London.

17929. Improvements in telephonic repeaters or relays and circuits connected therewith and therefor. Charles Adams Randall, 98, Prince of Wales Mansions, Prince of Wales-road, London, N.W.

17941. Improvements in or relating to electrical arc lamps. Henry Bevan Swift, 19, Southampton-buildings, Chancery-lane, London.

OCTOBER 10.

18000. Improvements connected with overhead trolley poles used in electrical traction. William Ellison Rowlands, 10, St. George's-crescent, Liverpool.

18001. Improvements in or applicable to switches for electromotors. Joseph Platt Hall, 70, Deansgate, Manchester.

18006. Improvements in conduits for electric conductors. Hosea Tugby, 47, Lincoln's inn fields, London.

18031. Improvements in telephone systems. Milo Gifford Kellogg, 24, Southampton buildings, Chancery-lane, London. (Complete specification.)

18036. Improvements in or relating to thermo-electric generators. Alfred Julius Boult, 111, Hatton-garden, London. (Albert Tissier, France.)

18044. Improvements in or relating to covering the conductors of multiple or other telegraph or telephone low capacity cables. George Edward Heyl-Dia, 6, Lord-street, Liverpool.

18045. Improvements in distributing heads or terminal boxes for electric cables. George Edward Heyl-Dia and W. E. Hitch, 6, Lord-street, Liverpool.

18056. Improved encasement for electric cables. Eugen J. Kiss, 18, Southampton-buildings, Chancery-lane, London.

18058. Improvements in magnetic rotary motors. Emile Dinoire, 72, Cannon-street, London. (Complete specification.)

18059. Improvements in electrical earth lines. Giovanni Battista Marzi 72, Cannon-street, London. (Complete specification.)

OCTOBER 11.

18066. Improvements in electrical exercising apparatus. Alfred M. Crooker and Frank N. Macdonald, Fife House, Kingston-on-Thames.

18067. Improvements in electric stop motions for warping machines. Frank Ashworth Holt, 17, St. Ann's square, Manchester.

18099. Improvements in or relating to electrically-driven vehicles. Ferdinand Porsche, 111, Hatton-garden, London. (Complete specification.)

18114. Improvements in polyphase alternating-current transformers. Carl Schaller, 6, Lord-street, Liverpool. (Complete specification.)

18119. Improvements in connections for electric fuse-boards, switches, and like apparatus. Herbert Dudley Barlow and Leonard Barlow, 18, Southampton-buildings, Chancery-lane, London.

18127. Improvements in the distribution of electricity to a plurality of electromotors. Thorsten von Zweigbergk, Clun House, Surrey-street, Strand, London.

OCTOBER 12.

18156. An improved method of automatically regulating the flow of liquids, gases, electricity, chemicals, and powders. William Player Miles, St. Cuthbert's, Grove Park, Kent.

18175 An improved advertising clock either combined or not with an electric alarum or call. Paul Royer, 52, Chancery-lane, London. (Complete specification.)

18184. Improvements in shades of electric incandescent lamps. The Spiral Globe, Limited, and Ernest André Livet, 53, Chancery-lane, London.

18195. Improvements in or relating to incandescence electric lamps. Peter Kopp, 322, High Holborn, London.

OCTOBER 13.

18233. Improvements relating to electric terminals for cable connections. Robert Frederick Hall, 24, Temple-row, Birmingham.

18234. Improvements in electrical switches or contact breakers. Robert Frederick Hall, 24, Temple-row, Birmingham.

18235. An improved lighting device for electrically lighting miners' safety lamps. Lewis Noah Williams, Lloyd's Bank-buildings, Bristol.

18254. An automatic switch to be used on wires carrying electric currents for the purpose of cutting off these currents when the main wires break from any cause, or are otherwise interrupted. Patrick Browne, 36, Chancery-lane, London.

18269. Improvements in or relating to the electrolysis of fused chlorides or metallic salts. Edgar Arthur Ashcroft and James Swinburne, 111, Hatton-garden, London.

Digitized by Google

18281. Improvements in the control of electric motors and similar devices from several different points, and in the means therefor. Harry Ward Leonard, 46, Lincoln's-inn-fields, London.

18282. Improvements in the junction boxes for electric cables, and in forming branch connections therefrom. Joseph Alexander Jeckell, 46, Lincoln's-inn-fields, London. (Complete specification.)

18283. Improvements in junction boxes suitable for connecting electric conductors. Joseph Hetherington and the British Electric Transformer Manufacturing Company, Limited, 46, Lincoln's-inn-fields, London.

18284. Improvements in electric transformers. Arthur Francis Berry and the British Electric Transformer Manufacturing Company, Limited, 46, Lincoln's-inn-fields, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Nov. 3.

1899.

23389. Transmitters for Morse alphabet and printing telegraphy. Cerebotani and Moradelli.

23391. System of telegraphy. Lorrain. (Bedell.)

23909. Electric lighting of railway vehicles. Hill. (Date applied for under International Convention, April 14, 1899.)

24791. Boxes or cases for containing switches and mechanism connected therewith for electrical traction. Kingsland.

24792. Method of and means for carrying and connecting strikers to motor vehicles for mechanically operating electric switches. Kingsland.

1900.

622. Incandescent arc and other lamps. Bonhivers.

6540. Electric railways on the conduit system. Stein and Freund.

10974. Electric accumulator electrodes or plates. Ricks.

12672. Manufacture of glass by electrical heating, and apparatus therefor. Voelker.

12673. Manufacture of glass by electrical heating. Voelker.

13969. Insulated electric conductors. British Thomson-Houston Company, Limited. (Emmet.)

13973. Insulated electric conductors. British Thomson-Houston Company, Limited. (Emmet.)

14275. Electro-chemical or copying telegraphs. Dymond. (Kopier Telegraph Gesellschaft mit beschränkter Haftung.)

14281. Telegraphy by means of alternating currents and imperfect contacts. Ferrié. (Date applied for under International Convention, Jan. 9. 1900.)

15918. Electrical phase transformation. British Thomson-Houston Company, Limited. (Lunt.)

15919. Electric rotary transforming apparatus. British Thomson-Houston Company, Limited. (Davis.)

NOTES.

The Zeppelin Airship.—Much has been said in the daily Press with respect to the airship invented by Count Zeppelin, but as tests do not seem to have been made when circumstances would be against its success, it yet remains to be seen how far the balloon is navigable. It is interesting, however, to note that between the two cars is a triple signalling arrangement and electric bells, and also signals for switching in or off the motors. There is also stated to be a telegraph and telephone.

Ship and Shore Telephones.—The Hamburg-American liner "Augusta Victoria" has, we learn from the American Press, been equipped with an automatic telephone pay station, which enables passengers to use local or long-distance telephones up to the time of sailing. Just before the lines are cast off a plug is removed from the telephone, cutting off the connection. If the scheme is found to work satisfactorily, it is proposed that other steamers of the company shall be similarly equipped.

Personal.—We are pleased to note that Mr. T. W. W. Melhuish, who has for 14 years acted in Vienna as manager and chief engineer of the central electric lighting station of the Imperial Continental Gas Association, has recently been appointed consulting and inspecting electrical engineer to the association and some other companies in which the association is interested. Owing to this change he is about to remove to 23, Boulevard Militaire, Brussels, as this town is more conveniently and centrally situated as regards his new duties, in which we wish Mr. Melhuish every success.

A Northampton Telephonic Novelty.—There have recently been made in Northampton a number of sanitary improvements in various portions of the town, amongst these being several underground conveniences. In the attendant's office in one of these underground lavatories, that at Woodhill, there has, we learn, been installed a penny-in-the-slot telephone, and consequently, in addition to its original purpose, the further convenience of a public telephone call office has been added. The idea seems to us to be new, and makes a very practical departure in connection with municipal work.

A Ceylonese Railway.—Having regard to the advance of electricity both for lighting and traction purposes in India, it is rather astonishing to learn that in Ceylon the governor has recommended the use of electric traction on the Uda-Pussellawa Railway, but that the consulting engineers of the railway have reported against the proposal as a new-fangled idea. We hope, however, that those having charge of the railway system will have a more complete investigation of the question of electrical traction, when they would probably decide against the engineer's advice, and have electrically-propelled trains.

House-Moving by Electricity.—A novelty in moving has, we learn, recently taken place in Wellsville, Ohio. As is well known, in the United States many of the houses are built so that when the owner is tired of one locality he can move into another by taking his house and wheeling it off to the desired spot. This has formerly been an occasion when the aid of traction engines has been necessary, but in places where electric trolley lines exist the traction engine is not given so much work. The house at Wellsville was moved into a street in which was an electric car line. Two of the cars were coupled to the house, which in this way quickly arrived at its new destination.

Calcutta Electric Supply.—Towards the end of last month India was visited by very heavy rain, and at Calcutta no less than 30in. fell in two days. This, as might be supposed, would not tend to improve the condition of the electric light mains, as the streets were cut up, and in many places subsidences took place. For some reason a serious fault developed in one of the electrical mains, necessitating the cutting out of half the Calcutta supply, and the lights and fans in one area were not working. The fault was, however, found as soon as the streets were in a condition to allow it, and supply was shortly resumed over the whole system. Considering the whole state of affairs, it reflects very creditably on the Calcutta Electrical Supply Corporation that they managed to keep even half of the supply available for use.

The Society of Model Engineers.—The seventh monthly meeting of the Liverpool branch of the Society of Model Engineers was held on Saturday, the 13th inst., in conjunction with the inaugural meeting of the Balfour Institute, at which the Right Hon. the Earl of Derby, K.G., was present. A good collection of models made by members of the society was on view, including, amongst others, two large and well-finished model steamers, the "Majestic" and the "Hawk," the former being an exact counterpart in miniature of the White Star liner of the same name (shown by Mr. Rimmer), a large horizontal engine, dynamo, and boiler (by Mr. Dawson), a launch engine and boiler (by Mr. Croker), etc. The models, which were greatly admired by the members and visitors, were inspected by Lord Derby and a number of other well-known gentlemen.

A Telephonic News Distributor.—There is, we gather, in Budapest a news telephone, which, we should think, would cause great dissatisfaction amongst the owners of daily papers. The object of this telephone is to keep its 6,000 subscribers supplied with all the latest news. The service has a main wire 168 miles in length, and it is connected with private houses and various public resorts. From 7.30 in the morning until 9.30 in the evening, 28 editions of news are spoken into the transmitter by 10 men possessing loud, clear voices, working in shifts of two. The news is classified and given in accordance with a regular programme, and the service has been eminently successful. We are not informed how much extra the subscribers have to pay for these 28 feasts of news daily, but we should imagine that they would find it better to buy a newspaper which they could read quietly at any place rather than go to their telephone at stated intervals and have the news shouted at them.

Meteorological Observations.—In an article dealing with the meteorological observations with kites, *Pearson's Magazine* mentions the good work done by Major-General Baden-Powell in connection with the use of kites for military purposes in place of the cumbrous army balloons. In the Trappes Meteorological Observatory, France, kites are also used for making observations. Most of their work is done by pilot balloons, but recently Hargrave box kites from 6ft. to 8ft. in height have been tried. These kites are secured to a windlass, upon which nearly 11,000 yards of steel wire are wound. The windlass is driven by an electric motor, which raises or lowers the kite as required. An instrument fixed at the ground end of the wire shows the length of wire paid out, and also the angle of its inclination. Within the box kites are placed instruments to measure the temperature, pressure of the atmosphere, and hygrometric condition of the atmospheric strata which have been traversed.

Glasgow and West of Scotland Scientific Society.—We have received the programme for the eighth session of the Glasgow and West of Scotland Technical

Digitized by Google

College Scientific Society. The president for the session is Mr. David Home Morton, and the hon. secretary is Mr. Andrew Stewart, 13, Barrland-street, Glasgow. The meetings, which are held on Saturday evenings at 38, Bath-street, Glasgow, commenced on Saturday last, Oct. 20, with the presidential address. Including this meeting, there are 14 meetings in the session, the next being on Nov. 3, when Mr. T. J. Nicholls will read a paper on "Theory, Technique, and Practice." Other interesting papers and discussions are on "Slow-Speed Engine Design," by Mr. A. M. Downie; "The Organisation of a Workshop," by Mr. H. P. Jackson; "The Overstraining of Iron," by Mr. Jas. Muir; "Boiler Shop Machine Tools," by Mr. R. Mitchell; "Diatomite," by Mr. R. B. Stewart; "The Progress of Electricity Supply," Mr. J. G. Scott; etc. On Feb. 16 the annual social meeting is to be held, and in April, May, and June various engineering and electrical works are to be visited. It would appear from the list of papers that the session will be one of unusual interest, both to the members and the friends whom they invite.

The Rating of Incandescent Lamps.—The paper by Prof. A. J. Rowland, which we are now reproducing in our columns, calls attention to what the professor considers are errors in the usual methods of rating incandescent lamps, on account of the great differences which exist between the horizontal and vertical candle-power in such lamps. His arguments are worthy of careful study, but we think he neglects too much the illuminating effect which is obtained by reflection. For instance, in an ordinary room with a light wall paper, and when the ceiling is newly whitewashed, a large proportion of the illumination of any particular part of the floor is due to reflected light from the walls and ceiling. While this is the case, the actual distribution, or rather radiation, from the incandescent lamp, is not quite so important as the author would lead one to believe. It reminds us somewhat of the extravagant claims which were made for the candle-power of searchlights. The figures in these cases were got by supposing that the whole of the light emitted from the arc was concentrated in a straight beam, which then had millions of candle-power. Thus, while we agree with Prof. Rowland that in the majority of cases the light from incandescent lamps should be thrown downwards, we do not think that the faults are quite so grievous as he makes out.

Medical Electrical Appliances.—It will be remembered by those who listened to the paper which Dr. L. Jones, of St. Bartholomew's Hospital, that he stated that an easily portable medical electrical apparatus was badly needed. This was one of the great reasons why electricity was not used to a much larger extent than at present in medical practice, and surgeons had to rely upon their own hands in cases where an electrical saw would be of immense advantage. Messrs. Isenthal and Co., of Mortimer-street, W., now claim to have produced an apparatus which is suited to the use of doctors and surgeons. The apparatus consists of a transformer for cautery work and surgical exploration lamps. The instrument uses continuous current, and is stated to have an efficiency of 80 per cent. No attention is needed, and the instrument may be connected to a wire of any size. On a 200 volt circuit no more than half-ampere is used, and the weight of the apparatus is no more than an ordinary accumulator. The conductors can be easily fitted to an ordinary electric lampholder, and two sliding rheostats for the simultaneous use of cauteries and lamps are provided. The apparatus is lower in price than the ordinary outfit for cautery work, the price complete being only £12. Granted that the machine performs the work and has the advantages claimed for it by the makers, it should be a step towards giving Dr. Jones the apparatus for which he asked.

Municipal Telephones. — At the autumn general meeting of the Association of Municipal Corporations, held on Tuesday at the Westminster Palace Hotel, the first business was to receive the report adopted at a conference of corporations interested in the telephone question on July 31 last, which stated that a sub-committee was appointed to obtain information respecting municipal telephones. The committee consisted of representatives of Manchester, Salford, Bolton, Hull, Plymouth, Sunderland, Huddersfield, Wigan, Southport, and Eastbourne. Expert assistance was obtained, and subsequently a deputation, consisting of the chairman of the committee and the vice-president of the association, was appointed to interview Mr. Hanbury with a view of eliciting further information. In reply, Mr. Hanbury said the Government would give a fair consideration to any request for a postponement of interest and sinking fund charges for a period of, say, three years. That if the Government acquired the plant at the termination of the license, he saw no reason why they should not acquire it at a price, and the money to be paid to furnish the means of paying off the borrowed capital. With respect to the withdrawal or modification of the royalty of 10 per cent. on the gross receipts, Mr. Hanbury could hold out no prospect of such relief at present. The adoption of the report was moved by the Mayor of Huddersfield, and agreed to.

Electric Lighting in St. Marylebone.—The Vestry of St. Marylebone is evidently determined to have no deathbed repentance on the question of electric lighting. On the one hand, it might be said that they will leave the new borough council, which is to replace the Vestry, a free hand in dealing with the electric lighting of the district. It must be remembered that this free hand will be seriously hampered by the way the Vestry conducted its negotiations with the Metropolitan Electric Supply Company in the past. What with agreements to purchase which have not been ratified by the Vestry, valuation disputes, and a general obstructive policy, the Metropolitan Company can but have a poor opinion of the administrative ability of the St. Marylebone vestrymen. As an example of the obstruction, we see that at their last meeting, which was held on Tuesday last week, the Electric Lighting Committee again recommended that the consent of the Vestry should not be given to the Metropolitan Electric Supply Company laying mains in Edgware-road and in certain other streets. We had hoped that the Vestry would have repented of its evil ways before departing this life, but such is not the case. What the ultimate result will be as far as electric lighting is concerned it is difficult to foresee, but we hope that the new borough council will elect a strong electric lighting committee able to develop a businesslike policy, and to secure the support of the other members of the council in carrying that policy through. If this had been the case with the practically defunct Vestry of St. Marylebone, there is no reason why there should not have been a municipal supply at the present time.

Institution of Mechanical Engineers.—The first monthly meeting of the session was held in the Institution House, Storey's-gate, on Friday evening last, when Sir William H. White, the president, occupied the chair. Mr. E. Worthington, the secretary, read a communication from the Society of German Engineers, Berlin, stating that German engineers recognised the necessity of having a reliable technical dictionary in the three

Digitized by Google

languages—German, English, and French—that the society would be glad if scientific societies in England and France would give their assistance in the production of such a dictionary, and asking if the Institution of Mechanical Engineers would appoint members to assist in its production. It was stated that the council had decided that the institution as a body could not take any action in the matter, but had informed the German society that the proposal would be placed before the members with a view to obtaining individual assistance. The President said that there was no want of sympathy on the council's part with respect to the movement, and the only question was as to the best way of giving effect to the suggestion. Prof. Smith said the matter was important. There was great need for such a dictionary, which should also be published in Italian as well as the three languages suggested. The President said that the names of any members willing to assist would be communicated to the German society, and a note on the subject would be circulated amongst the members. A paper by Mr. Bryan Donkin, entitled "Observations on an Improved Glass Revealer, for Studying Condensation in Steam-Engine Cylinders, and Rendering the Effects Visible," was afterwards read by the secretary. The customary discussion followed.

The Electrical Boom.—There is no doubt that exceptional activity is being shown in the construction of new electrical manufacturing works in this country. One result will be that, unless the old-established businesses are prepared to extend their borders, they will find that they are seriously hampered in their competition with their new rivals by the inconvenience of works which have been erected piecemeal, and by machinery which is not of the latest date. As an example of the large new works being started, we have the Westinghouse Company erecting large works near Manchester, and the British Thomson-Houston Company are also erecting manufacturing works near Rugby. These will compete with the other firm engineered by Americans, and called the English Electrical Manufacturing Company, who have already commenced active operations in their new factory near Preston. We are therefore pleased to note that these three firms are not to have a monopoly of new machinery and conveniences in the arrangement of their buildings, as the old-established firm of Messrs. Siemens Bros. have also decided to move their manufacturing works to the Midlands. For this purpose land has been secured near Stafford, on which the new works are to be erected at an early date. We understand that great care is being paid to the design of these works so as to facilitate the manufacturing of dynamos and motors in quantity and at the cheapest possible rates. The arrangement of the various departments will also be such that there will be a minimum waste of time in transferring the goods from one department to the other. The cable works of the firm will not be moved from Woolwich, and the space set free by the transfer of the manufacturing department will enable a much larger quantity of cables to be turned out in the larger space available.

Midland Engineers.—A joint meeting of the members of the Chesterfield and Midland Counties Institution of Engineers and the Midland Institution of Engineers is to take place next Thursday, Nov. 1, at the Blackwell Collieries. On this occasion several of the collieries belonging to the Blackwell Company are to be thrown open for inspection by the members. Two routes have been arranged, the first of which is to Alfreton, Shirland, and Blackwell (A winning) Collieries, and the second to Alfreton and Blackwell (B and C winning) Collieries. At 2.30 p.m. a luncheon is to be given the members by the directors of the colliery company, and at 3 p.m. a joint meeting of the members of the institutions is to take place. At this meeting a number of papers which have already been published, dealing with mining engineering, will be discussed. With respect to the collieries to be visited, we learn that in A winning of the Blackwell Colliery the screening of the coal is done mechanically. The ventilation is effected by a Guibal fan, 45ft. in diameter and 12ft. wide. Electric lighting is used both on the surface and underground. Some of the boilers in this winning are heated by waste gases, the other boilers being of the Lancashire type. In the B winning of this colliery the electric light and main and tail rope engines are now in course of erection. In both the Alfreton and Shirland Collieries electric light is used above and below ground, but in the latter colliery electricity enters to a greater extent than in the others. Thus coal-cutting electric generating plant is used in the Shirland Colliery, it consisting of one pair of Robey horizontal engines with two 10ft. driving and fly wheels, two dynamos, one being a compound-wound underhung four-pole machine, producing 180 amperes at 420 volts and 600 revolutions. The other is a compound-wound underhung two-pole machine producing 175 amperes at 420 volts with 450 revolutions. The coal-cutting machines are four Clarke and Stevenson's machines with 4ft. 6in. undercut, and one "Garforth" machine with 5ft. 6in. undercut. Two electric three-throw pumps are also used in this colliery.

British Canals.—Mr. C. C. Capel, in a letter to the *Journal* of the Society of Arts last week, calls attention to the large number of canals in the British Islands which are allowed to fall into disuse. He suggests that these old canals should be restored, and that the falls of water on them should be used for the generation of electricity, which, he considers, could easily be obtained in this way at a very cheap rate. We quite agree with the author as to the way in which certain canals have been allowed to fall into disuse because they competed with certain railway companies, who, having acquired the controlling power in the canals, have deliberately neglected them. There is no doubt that a number of these, if in repair, would be able to transport goods by electric power at a rate which would be very much lower than is charged on the adjoining railways. We would, however, join issue with Mr. Capel on the other question—*i.e.*, the utilisation of the fall of the canals for electrical power generation. Even in the winter there is not the fixed amount of useful power in an ordinary canal which the writer would lead one to expect, and, as a rule, the power available in the dry weather is almost negligible. It must also be remembered that the cost of establishing any water-power scheme, if considered in comparison with the possible output, is always high for small installations. In the same way, with a transmission line, the actual cost of erecting the line is to a certain extent independent of the size of the conductors which are carried, and hence the capital charges in a small installation become prohibitive if the power is to be transmitted to any considerable distance. As an example of this, we would point to the various mills throughout the country which are situated on small streams where from 10 h.p. to 50 h.p. can be obtained. It will be found that these mills, in spite of the fact that their power costs them next to nothing, are not able to compete with the large steam flour mills. We would therefore warn Mr. Capel that, as far as power is concerned, there is little to be expected from our canals We quite agree with him that as a means of traffic for heavy goods, and also for excursion purposes, it may be well to repair certain of the old waterways.

The Paris Accident.—On Friday last the new Metropolitan Railway of Paris, which, it will be remembered is

Digitized by Google

engined by electric locomotives, was the scene of an accident which we are afraid will shake the confidence of the travelling public in the equipment of the line. From the various reports which have reached us we gather that the fault was due to defects in the signalling arrangements. The line is worked on the absolute block system, but we believe that the signalling is done automatically by the passage of the trains along the line. It happened that a certain train was stopped as it approached the station up a considerable incline. Before the driver was able to prevent it the train ran back a short distance, and it is presumed that in so doing it reversed the danger signal, which it had previously caused to be given behind it. The next train, therefore, proceeded on to the section, and ran at full speed into the rear of the standing train. The result was that about 30 people were injured, and two of them seriously. The driver of the train which ran into the standing one was naturally in the position of most danger, and his injuries are expected to be fatal. The confusion resulting on this accident was made worse by the extinction of all the lights in the tunnel, so that the passengers were absolutely in the dark. We have not by us a record of the exact means used in lighting the tunnels, but this accident shows how important it is to have the lighting independent of the supply to the trains, and also to have it so arranged that an accident to the wiring cannot easily occur. In fact, it would be almost worth while to have a duplicate system of wiring, so that alternate lamps in the tunnels are on independent circuits. If the accident was due to the fault of the block system above referred to, there should not be much difficulty in rectifying the mistake in the system used by which such a reversal of the danger signal is possible when a train runs back along the line. We regret to find that the Metropolitan electric line in Paris is not giving such satisfaction as our Central London line. We hear, too, bad reports of the character of the rolling-stock, and also as to the want of punctuality of the system.

Electricity in India.—The *Gazette of India* recently published the draft of a new set of rules under the Indian Electricity Act. In these considerable modifications of existing rules have been introduced. Commenting on the subject, our contemporary, *Indian Engineering*, says that it would be extraordinary if the rules made for England suited all the conditions of India. It also thinks that the protection of the Board of Trade has been somewhat too inclusive, and instead of helping on the electrical industry in England, has rather kept it back. This is not, however, without its advantages, as while others have experimented and either gained or lost considerably England has gone on steadily, noting the good and bad points in other systems and utilising the best of them. In this way our contemporary thinks that the English work of the last few years has been more solid, safe, and lasting and less unsightly than any other in the world. As to the transmission of power, the power schemes in England are mentioned, and the cost of insulating if the Board of Trade rules are enforced commented upon. This cost of insulating, the writer thinks, would give the quietus to any scheme involving distance transmission in India. The Swiss method is spoken of, where conductors are carried overhead, and all the companies do is to put danger marks on the poles carrying the cables, whether they are bare or insulated. The new Indian rules pursue an intermediate course by stating that in towns and elsewhere the Government thinks fit the wires are to be insulated up to the Board of Trade standard. As to the power to be carried by any particular high-tension wire, the Board of Trade limits are thought to be unnecessary, and in the new Indian rules, as far as aerial lines are concerned, it is left for each local government to settle the matter according to climatic conditions. The limit of 300 kw. has been fixed for lines that are not aerial, this probably being fixed owing to the fact that it is advisable to have duplicate lines, in case one supply were stopped owing to heavy rains or other causes. The rules respecting the prevention of electrolytic action owing to currents used for traction purposes, have in these Indian rules been made stricter than in England, but these rules can, if necessary, be modified at the discretion of the local government.

The Nobel Prizes.—The formal rules and regulations respecting the awarding of prizes under the Nobel bequest have now, we learn, been drawn up and published. The three bodies selected to award the Nobel prizes are the Royal Academy of Science at Stockholm, the Swedish Academy at Stockholm, and the Carolin Institute of Medicine and Surgery at Stockholm. The first award will take place on Dec. 10, 1901. The prizes are to be awarded as follows: to the person having made the most important discovery or invention in the department of physical science; to the person having made the most important discovery and having produced the greatest improvement in chemistry; to the author of the most important discovery in the department of physiology or medicine; the author having produced the most notable literary work in the sense of idealism; to the person having done the most, or the best, in the work of establishing the brotherhood of nations, for the suppression or the reduction of standing armies, as well as for the formation and the propagation of peace conferences. The award for physical science and chemistry is to be made by the Swedish Academy of Science, that for medicine or physiology by the Carolin Institute, that for literature by the Swedish Academy, and for the work in the cause of peace by a committee consisting of five members elected by the Norwegian Storthing. As stated in the will of Dr. Nobel, nationality will not be considered, the worth of the papers, etc., alone being taken into consideration. Each of the prizes must be awarded at least once every five years. In order to be admitted to the competition, every written work must have been published by means of the printing press, and it is also necessary that intending competitors should be proposed by some qualified person, no attention being paid to requests from competitors themselves. At the solemn *réunion* which takes place on the anniversary of the death of the donor, Dec. 10, the corporations will make known publicly their decision and bestow upon the laureate a cheque for the value of the prize, a diploma, and a gold medal bearing the effigy of the donor with an appropriate inscription. The laureate is obliged, unless prevented by unforeseen circumstances, to give during the six months following each *réunion* a public lecture on the subject of the work crowned. The lecture will be given in Stockholm, or for the peace prize in Christiania. Decisions in regard to the prizes are without appeal. The prizes, it would appear, are well worth winning, those which will be distributed in 1901 amounting in all to £80,400, or £16,080 for each division.

Accumulator Traction.—The leading article in the current issue of the *Elektrotechnische Zeitschrift* deals with the report of Dr. M. Kallman on the competition between electrically-propelled vehicles which took place in Berlin last spring. We have previously referred to this competition, and applauded its thorough character; it is, therefore, interesting to learn the results obtained. It will be remembered that each vehicle was tested on 50 different issues. We now learn that the best of the competing vehicles was awarded 41·71 of the possible 50 points, while the second

Digitized by Google

and third best received 39 71 and 38 53 points respectively to their credit. These figures show, as our contemporary remarks, that according to the view held by the special commission delegates to conduct the trials, the best vehicles actually attained to a high degree of perfection. As especially significant, Dr. Kallmann mentions that breakdowns during the six days over which the trials extended, when the vehicles were subjected to a heavy demand, were remarkably few. As regards the weights of the batteries employed, it must be mentioned that the battery taking first honours in this respect had a weight of 121lb. per kilowatt-hour, while the least favourable case was that of a battery weighing 286lb. per kilowatt-hour. The mean value for the 13 vehicles taking part in the competition was 165lb. The initial cost of these batteries varied in the case of the passenger cars between £50 and £100, and in the case of the freight cars between £60 and £125. The costs of the complete cars, including batteries, varied between £185 for the smallest and £450 for the largest passenger cars. In regard to the freight cars, this cost varied between £225 and £400. It follows, therefore, that the cost of the battery equipments of the several vehicles amounted to between one-third and one-sixth of the total cost, and Dr. Kallmann expresses the opinion that the cost of the battery for a passenger car to travel 19 miles with one charge will amount in the future to about £50. So far as concerns the maintenance and renewal of the batteries, one firm guaranteed 250 charges and discharges. A much more favourable offer was made, however, by another firm, which asked for an annual sum amounting to 30 per cent. of the initial cost of the battery, for which it undertook to maintain, and if necessary renew, the battery for three years without further compensation. Upon the assumption of a yearly total mileage of 9,500 miles, Dr. Kallmann calculates the annual maintenance cost of a battery at only ·48d. per mile. The smallest consumption of energy per ton-mile at the mean speed amounted to 91 watt-hours for a passenger car, a far better performance than previous records are able to show. At the highest speed the consumption increased to 135 watt-hours. However, in the majority of cases the demand did not vary greatly with the speed, which makes Dr. Kallmann come to the conclusion that, in order to obtain the greatest commercial economy of energy, the electrically-propelled car should be driven at the highest speed consistent with public safety. By the high speed the consumption of energy per car mile is not considerably increased, while the number of passengers which may be transported in a given time naturally increases with the speed. The best freight car showed a consumption of energy amounting to 123 watt-hours at low speed, 126 at mean speed, and 134 at the maximum speed. With regard to the size of motor best adapted for the weight to be propelled, Dr. Kallmann gives it as a rule that the capacity of the motor should amount to approximately 1 kw. per ton of the rolling weight. In respect to steering and braking, the cars competing varied considerably in efficiency. One car was pulled up when travelling at a rate of 11·1 miles per hour over level asphalte pavement within the space of 12ft. 3in., the same car travelling at a speed of 11½ miles per hour over a paved road being pulled up within 16ft. 6in.

Rhodesian Rubber.—A report has been prepared by Mr. Lyttleton Gell for the British South African Company with respect to the rubber industry in their territories. The report, which is published in the *Board of Trade Journal*, states that it has now been ascertained that extensive tracts in North-West and North-East Rhodesia produce natural rubber of high commercial value, while in South Rhodesia indigenous rubber is reported in abundance in the Sabi Valley and along the Zambesi. There is also good ground for believing that valuable foreign species can be cultivated in the district. The native methods of extraction are at present very destructive and the methods of preparation faulty, and this impairs the market value of South African rubber. It is urged with respect to the administration of the rubber industry that the indigenous rubber should from the first be recognised as State property, and not be abandoned to private exploitation. The problems to be faced thus are the measures necessary to preserve the existing sources of the rubber, the methods of obtaining a revenue from the industry, the future development and expansion of the industry, including the suppression of detrimental methods of extraction and preparation, and the policy towards proposals of exploitation. In other African territories regulations are in force which offer suggestions, although the rules are not very rigidly enforced. Thus in the Congo State no unauthorised extraction of rubber is permitted. The industry is largely worked by the State, but private concessions for limited periods are also granted. In each year a certain number of new trees must be planted in proportion to the amount of rubber extracted. The felling of rubber trees is absolutely prohibited, and extraction of root rubber is forbidden. At Lorenco Marques a monopoly of the production and trade in rubber for 25 years has been granted over the unoccupied State lands. The concessionaires pay a rent of about £44 per annum, and undertake to plant 20,000 trees in two years. They further pay a duty of 2½d. per kilo for seven years, rising to 4d. per kilo for the remaining eight years. They are exempt from all other imposts, and have the option of retaining the land at the same rent at the expiration of the monopoly. The monopoly does not restrain the cultivation of rubber on private property and its export by private persons. The Mozambique Company forbids any individual to purchase rubber from natives, or to extract it through agents, without a special annual license, which costs £3 per annum. A sum of 1s. 6d. per kilo must also be paid before rubber can leave the district in which it is collected. The system in Lagos is based upon a theory that the ownership of forests is vested in the local tribes under their chiefs. Within districts under the control of such chiefs no person may collect rubber without a license, for which he pays £5 to the "native chiefs" and 2s. for each load of rubber. No tree may be felled except with special permission, and on payment of 5s. per tree. The report concludes that there should be no hesitation in recommending that immediate regulations should be framed for North-West, North-East, and Southern Rhodesia for the protection of wild rubber which should embody certain well-ascertained principles—*i.e.*, a minimum age and girth should be established, below which a tree must not be tapped, the measurements being adapted to different species and localities. The intervals at which trees may be tapped should also be regulated. Subject to local modifications, it would be safe to forbid tapping the same trees, or the same area, in two successive years. A general regulation will be required that rubber may only be collected by tapping; that no tree may be cut down, and no roots grubbed up and boiled. A general regulation is desirable providing for the plantation of young rubber trees in forest land by persons extracting rubber. If in special districts the extraction of root rubber is permitted, the rate of replantation must be high, not less than two to one. With regulations following somewhat the above lines, the rubber industry in Rhodesia should become a very important commercial undertaking.

THE PHILOSOPHY OF DYNAMO DESIGN.

(Specially contributed.)

(Continued from page 557.)

The Armature Reactions.

In accordance with two of our fundamental principles—the discoveries of Oersted and Faraday—all modern dynamos are built to consist of two parts: an electro-magnetic part, comprising the magnets, yoke, pole-pieces, and field coils; and an inductive part, termed the armature. The field magnets (Fig. 3) consist of soft iron or steel wound with many turns of copper wire, so as to make a powerful electromagnet when a current flows along these turns. This current is usually, but not necessarily, supplied from the armature of the machine. The armature, which is placed between the poles of the magnets, consists of a mass of soft iron, which, in the case of a drum machine, may be keyed directly to the shaft. If, however, the armature is of large diameter, it is usual to cut away the centre of the armature core and key the iron on to the shaft by means of a spider; while, if the armature is to be ring or Gramme wound, this must be done whatever be the size of the armature. Upon this armature are wound various turns of wire insulated from and coupled up in series with each other, and having at equal intervals connecting pieces or lugs leading down to the commutator, whence the current is collected, as a uni-directed (or direct, as it is commonly termed) current. It is not necessary that all the inductors be in series with each other, as sometimes, in

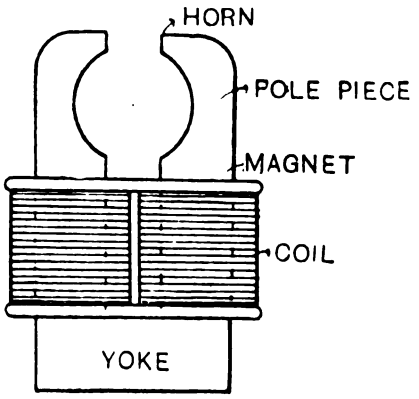

Fig. 3.

order to get a requisite cross-sectional area, two or more wires are wound in parallel to make one complete inductor, or the winding may be of the duplex, triplex, or other multiple type.

The method by which the current is generated is at first glance found to be simplicity itself. The coils on the armature are made to cut the lines of force passing between the poles of the electromagnets. It is in order to make the path of these lines as easy as possible that the armature core is made of soft iron. The lines of force proceed from the north pole of the magnet through the air-gap, which must exist as space to wind the armature wires in a smooth-core machine and as clearance between the revolving and fixed portions in all classes of machines, then through the iron of the core, across the second air-space and thence into the south pole of the magnet, and complete their circuit through the iron of the magnets and yoke. The usual practice is to make the armature revolve and the fields stationary, but this is not essential, and so long as there is relative motion of the coils and lines, either armature or magnets may revolve, or both may do so in opposite directions. The amount of current generated will depend upon the E M.F. and the resistance of the outer circuit; this is evident from our third principle that $C = \frac{E}{R}$. Hence, if E be only large enough or R small enough, C could be made of any desired magnitude, except that, in addition to Ohm's law, C is ruled by two other factors—viz, that every wire grows hot when a current is passed along it, and that the final temperature to which it will attain depends inversely upon the amount of cooling surface it has, and also directly upon the square of the current it carries, so that with a wire of any size a limit will be reached for the safe working current. If the current be increased, the wire will first get so hot that the cotton insulation will be burnt off, and if the current be still further increased the wire will fuse and melt. The second factor which rules the amount of current which can be taken from any armature will be dealt with in the section on the limits of load.

The value of the E M.F. which will be generated by any armature depends upon the number of turns of wires in series on the armature, the number of lines of force cut by these turns per unit time, and is given by the formula

$$\frac{E \times 10^8 \times 60}{N \times C_a} = \phi,$$

where N = revolutions per minute;
C_a = armature turns in series;
ϕ = total number of lines of force cut.

If N = 100, C_a = 100, and ϕ = 1,000,000, E will = 1·33 for a two-pole dynamo. Hence, if the value of E be required higher—and for direct-current dynamos this may be anything between four volts and 1,000 volts or more—one or more of the values of ϕ, C_a, or N must be increased. For dynamos of small output the increase would be largely in N and C_a, but for dynamos of large output, while N might be as high as 300, the great increase should be made in the value of ϕ.

However simple the above description of how the current is generated in an armature may appear, it is soon found

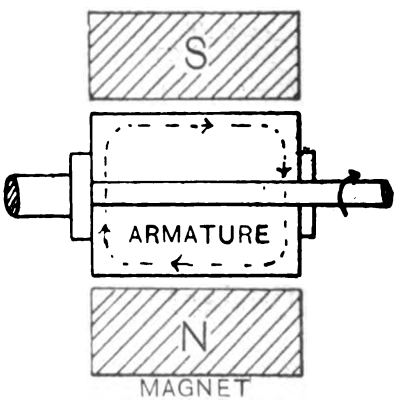

Fig. 4.

in practice that innumerable difficulties must be overcome before a satisfactory result can be obtained, and these difficulties are due to what are known as the armature reactions, but it will be found upon examination that all these reactions are due to causes produced by our fundamental principles, and can be foreseen and so guarded against.

From our second primary principle we learn that if a wire be moved so as to cut lines of force a current will be induced in it at right angles to the lines of force, and at right angles to the direction of motion, and from our third primary principle we know that the value of this current will vary directly as the E M.F. and inversely as the resistance. If, now, the wire be bent round so as to form a coil closed on itself, and then revolved in a magnetic field so as to cut the lines of force, it will be short-circuited on itself, and the current which will circulate around it will be enormous, even at a very low voltage, since R will be practically negligible. If, then, the core of the armature be made of one solid piece of soft iron, it would act as a coil of wire of large cross-section short-circuited on itself, and a current would flow along the dotted line in Fig 4; and the amount of this current would be so great that not only would the iron get hot, but also it would absorb nearly all the driving power, and if the dynamo gave a current at all to the external circuit, its efficiency would be ridiculously low. Since the E M F. will be very low—as there are only two inductors cutting the lines of force—very little will stop the flow of the current, and the usual method adopted is to build up the core of thin sheets of charcoal iron (preferably about No. 26 Birmingham wire gauge), having their laminations parallel to the flow of the magnetic flux due to

Digitized by Google

the field, and at right angles to the flow of the induced current, and each plate being insulated from its neighbour by means of shellac, varnish, oiled paper, or other insulating material. If these laminations are made thick, a current will flow through each lamination, but, according to the thinness of the plates, this eddy or Foucault current will grow less and less, until, by using plates thin enough, it can be brought to an indefinable amount, although in practice it is not found desirable to use plates less than the gauge mentioned. Considering that it is on these two primary principles which cause these Foucault currents that all modern dynamos are built, it does not require practical experience, but only simple reasoning, to see that, unless means are taken to prevent their production, Foucault currents will be induced in the armature core; their value could also be readily calculated if necessary, knowing the thickness of the laminations, the magnetic flux, and the amount of iron in each of the circuits, and, therefore, their resistance. These Foucault currents will also arise in the inductors or wires wound on the armature core if they have any considerable width and are solid, for it is evident that if the speed of the armature is constant, the peripheral space traversed by any one inductor will always be the same, but the number of lines cut for each element of peripheral space will vary, for referring to Fig. 5, where the lines of force are shown dotted, it will be seen that when an inductor is at A or B it is slipping through the lines, while at C or D it is cutting the maximum quantity per unit

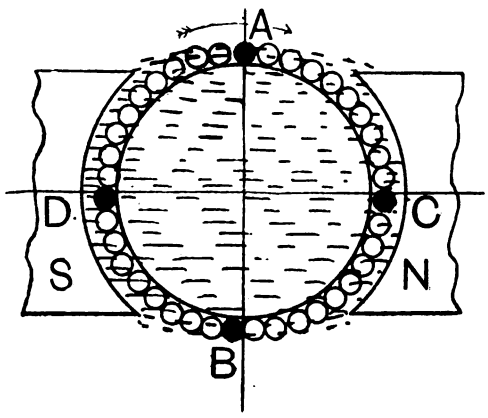

FIG. 5.

length, and that the number cut per element of time increases from A to C, then decreases from C to B, and increases again from B to D, and the cycle is completed by decreasing to its minimum at A. If the numbers of these lines cut per each successive element of time are plotted in the form of a curve on paper, it would be found that the resultant was a true sinusoidal curve. Upon examining this variation in the number of lines cut per unit element of time, it will be seen that the front or leading edge of any inductor is cutting lines at a faster rate than the trailing edge when travelling from A to C and from B to D, and at a slower rate when travelling from C to B and from D to A; hence there will be a difference of potential between the two sides, and an eddy or Foucault current will flow along the width of the inductor. If the inductor be very narrow, these eddy currents may become of slight moment; but if the bar be wide, they will be of the utmost importance—in any case they will have an appreciable effect on the heating of the armature. It may be urged that the difference of potential between the two sides will be so microscopic, even with thick bars, that a practical designer may neglect the effect, and consider the phenomenon as one interesting for a professor in a laboratory fitted with accurately measuring instruments, but of no importance in a commercial sense. But this is not the case at all. The student must remember that the resistance across the width of the bar is almost infinitesimal, and since $C = \frac{E}{R}$, it will therefore only require E to be of very small dimension for the value of C to be enormous. In order to minimise the effect of this difference in potential, various methods have been adopted. One is to wind the armature with several strands in parallel, but insulated from each other. The worst of this arrangement is that if the insulation, which need be only very slight so as to increase the value of R across the width of the bar, consisted of shellac or other varnish, as soon as the armature became hot it would melt and run out, while if the insulation consisted of cotton or other covering for the individual strands, not only would it be costly, but it would also occupy much valuable space. However, in October, 1886, Mr. R. E. B. Crompton took out a patent (12,880, Oct. 9, 1886) for a compressed strand having a twist over each other at or near the centre, so that as the compound inductor passes through varying portions of the field the E.M.F. in each portion may be the same. It will be readily apparent that as the foremost strand in one half of the inductor is the rearmost strand in the other half, any Foucault currents will be neutralised. This invention has been found of such great value that the patent rights have been maintained up to the present date, and all manufacturers use it for their large smooth-core machines, obtaining it from Messrs. W. T. Glover and Co., Limited, who make it under royalty.

The two phenomena due to armature reactions to be next considered must be taken together, and are due to the magnetic tendency of the current flowing through the armature coils, and are known as the back induction and cross magnetisation due to the armature current. Fig. 6 is a diagram of an armature placed in a magnetic

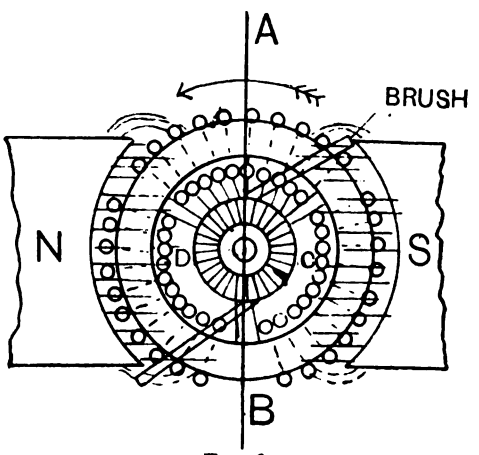

FIG. 6.

field, the line A B being drawn at right angles to the direction of the flow of the lines of force and equidistant from the horns of both field poles; this line may be called the neutral line. If, now, the armature be revolved, and the brushes be lowered on to the commutator, it might be supposed that the brushes should rest on those segments which are connected to the coils through which this neutral line passes, but in practice it will be found this is not the right position, and that to obtain sparkless commutation a forward lead must be given to them—*i.e.*, the brushes must be shifted to a position one or more bars in advance of the neutral line; in a motor a backward lead will be found requisite. If the north and south poles and the direction of rotation be as shown in the diagram, we shall with a right-handedly wound armature have a positive brush at the top—*i.e.*, a brush where the current is positive to the external circuit—and a negative brush at the bottom. Hence in the armature the current will flow from the bottom to the top, and will divide equally between the two sets of coils on the right hand and left hand of A B. Further, as shown in the diagram, the lines of force will not all flow across the air-gap in straight lines, but some will take at the horns an arcing path, creating a fringe, gradually varying from normal density to zero density between the horn and the neutral line. Now consider a coil in series C, which is coming up to the positive brush. This will be carrying a current in, say, a right-handed whorl When it passes into series D of coils, which are revolving away from the brush, the current will be flowing in a left-handed whorl, or, in other words, the current will be stopped and reversed in direction all within the minute period of time that the brush is covering the commutator section to

Digitized by Google

which the coil is connected. In the introductory portion, however, stress was laid on the truth of Lenz's law, that the action of self-induction was such as to maintain a current which is stopping and to oppose a current which is commencing. The law will then act in its full force in this case. It will first of all oppose the stopping of the current flowing in the right-handed whorl, and will equally as strongly oppose the starting of the current flowing in the left-handed whorl, and this action, known as the self-induction of the coil, will not only be the only magnetic force acting on the coil, as we presume it to be lying in a perfectly neutral plane, but also its force will be intensified by the iron of the armature core, round which the coil is wound. The result will be that the coil will pass into the D series utterly unprepared for its new work, and disastrous sparking will be the result, which could have been foreseen from first principles without the aid of experimental practice. The heavier the current carried by each series of coils, the stronger will be the self-induction of each coil as its current is first broken and then reversed. Now, the condition for sparkless commutation is that each coil, when it passes from under the brush shall have a current flowing in it equal in magnitude and direction to the current flowing in the coils which it is about to join. The only method of securing this is to let the reversal take place in a field of sufficient strength and direction as will generate in the coil while under the brush the required current. At the moment when the brush is passing over the mica insulation which is placed between two commutator segments, the coil which is connected to these two

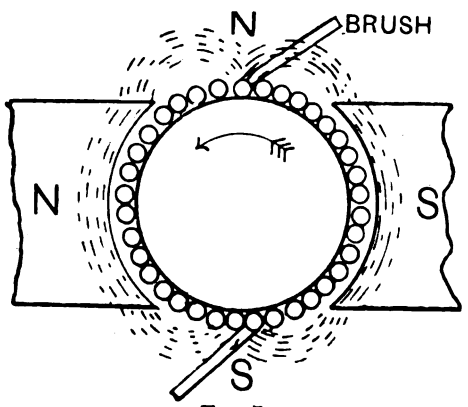

FIG. 7

segments is short-circuited on itself—that is, the two ends are joined together by the brush contact and practically isolates the coil from both the C and D series, so that any current which may be generated in this coil will flow round and round the coil. As the resistance of the coil is excessively low, a very low E.M.F. will create a large amperage, or, put in another form, the cutting of a very few lines of force per second will generate an E.M.F. sufficiently great to create a current equal to that flowing in the other coils, but as the output of the machine as a whole is increased, the amperage in the individual coils will increase, and a stronger E.M.F. will be required for reversing the current in the short-circuited coil, or more lines of force will be necessary to be cut per second by this coil, and so the coil under consideration must be placed in a stronger field. This is done by moving the brushes in a forward direction (in a dynamo) and short-circuiting the coil a little later. It may be advisable to mention here that since there is no obligation to bring the end windings out straight to the commutator lugs, they may, and often are, twisted through a certain angle, so that the angular position of the brushes on the commutator is nothing. The important point is the position the short-circuited coil itself occupies. Although the exact position in which the brushes of every dynamo must be placed is found by trial, a knowledge of the fundamental principles would teach that for any large variation of load the position must be altered, although it might be necessary to make a long and wholly unnecessary calculation to indicate the exact position, which can readily be found by trial.

If a shunt-wound dynamo be built for a large current output, it will be found that it will require a certain definite increase in speed to maintain the normal E.M.F. at full load to that which is requisite to maintain this E.M.F. at light or no load; the reason for this increase may be somewhat involved, but it is easily traceable to the three first principles. Consider for a moment Fig. 7, which represents diagrammatically a dynamo with a drum-wound armature running on open circuit; here the brushes are shown as resting on the neutral line. If now the load be largely increased, a forward lead must be given to the brushes as shown, perhaps somewhat exaggerated in Fig. 8. If the armature were held in one position, and a large current passed through its coils from the bottom to the top brush, assuming the armature be wound in a right-handed manner, it will be easily seen that the armature coils form a solenoid round the armature core, which, being of soft iron, increases the magnetic effect, and hence a north pole will be formed at the top and a south pole at the bottom, while the lines of force due to this magnet will flow through their external field practically as shown by the dotted lines in Fig. 7. This external field is called the cross-induction, or cross-magnetisation due to the armature, and is the condition which would obtain if the machine were to run at full load with the brushes on the neutral line. But it has been shown that with heavy loads a forward lead must be given as in Fig. 8, and a new condition is by this very fact brought into being; the armature coils can now be divided into two series. Draw a vertical line from the top brush, A to C, in Fig. 8, and also from the bottom brush, B to D; then the coils laying between A C and B D may be considered as a solenoid

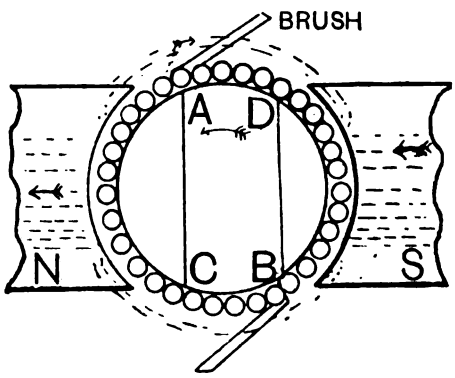

FIG. 8.

tending to form a north pole at the top and a south pole at the bottom, while the coils between A D and B C may be considered as a solenoid tending to form north and south poles at the sides opposite the centres of the pole-pieces, but it must be noted that in dynamos this induced north pole will be opposite the north pole of the magnet, and the south opposite the south pole. The effect of this arrangement is to weaken the field or forward induction, for, as shown in Fig. 8, the lines of force due to this armature reaction will flow in their external field in an opposite direction to the lines due to the magnetic field. Since the E.M.F. generated in any armature varies as the number of lines of force cut per unit time, it is evident that at heavy loads the E.M.F. will be less than at light loads, owing to this weakening of the forward induction; and since the strength of a solenoid depends upon the number of ampere-turns it is also evident that the heavier the load the greater will be the back induction, as it is called, of the armature, since a greater lead will be requisite, and hence not only a larger number of coils will be thrown into the A D, B C series, but also a heavier current will flow through them, both of which conditions are the factors which make the ampere-turns of the solenoid causing the back induction. If, then, former experience has taught what will be the probable angle of lead of the brushes at full load, a knowledge of the three fundamental principles added to a slight calculation will show what will be the rise in speed required in any specified shunt machine to maintain the E.M.F. of open load with a full load, or if a constant speed and E.M.F. are required at all loads, will show the number of series-turns required on the field in order to compound the machine properly.

Digitized by Google

Although it has been stated above that the cross-induction and back induction would arise were the armature held stationary and a current passed through its coils, yet the student will readily see that these conditions also obtain when the armature revolves; the induced poles are fixed as to place and not as to any individual coil, and consequently the flow of the field flux, as shown in Fig. 6, is only correct for an armature running on open circuit, but with a dynamo working with full load the final distribution of the lines of force will be obtained by superposing Figs. 7 and 8 on Fig. 6. This has been done in Fig. 9, which represents the normal arrangement of the lines in a machine running on its full load, as in ordinary circumstances the field flux would be maintained by increasing the magnetising power of the field coils, either by compounding or cutting out shunt resistance. The effect of the back inductance is not shown, and Fig. 9 is really a superposition of Fig. 7 on Fig. 6.

It will be seen that the result of the cross-magnetisation due to the armature being superposed upon the forward induction is that the final field is very much distorted. At the leading horns, A D, the directions of the two lines of force are opposite, and they become assimilated, while at the trailing horns, B and C, the directions are the same and the lines of force augment each other, and the field is intensified. This weakening of the field at the leading horns is a disturbing element in finding the exact position for the brushes at full load, as the

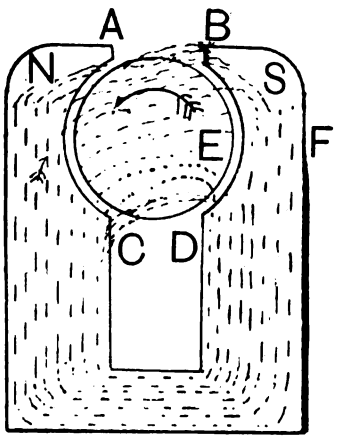

FIG. 9.

field does not uniformly increase as it would were it not for the cross-induction, and also as the brushes are given a more forward lead owing to the heavy load, not only is the strength of the solenoid creating this cross-induction increased, owing to the greater number of amperes flowing through the armature, but also the positions of the poles of this solenoid are brought nearer to the leading horns, and consequently the field under these horns is still further diminished. The great disadvantage of this weakening of the field at these points is that if the brushes were fed too far under the polar tips they would soon come into a very dense field, which will generate in the short-circuited coil a current far in excess of that carried by the D series of coils, and disastrous sparking will ensue, as will be seen when we treat of the theory of commutation. Hence it is most important that there should be no sharp line of demarcation between a neutral field and a dense field, but rather a gradual shading off of the field. Various devices, such as boring the poles elliptically, have been suggested and tried in order to secure a suitable magnetic fringe at the horns, and some of these methods will be dealt with in a later chapter.

When dealing with the cross-magnetisation, we assumed that the armature was held stationary and a certain current passed through its coils, and Fig. 7 shows the lines of force flowing equally through the two poles. This is what in practice would occur; if, however, one pole-piece were removed, the reluctance of this path would be enormously increased, and practically all the lines would flow through the other pole, and the external field would not bifurcate, as shown; if in place of removing one pole-piece its cross-sectional area were greatly diminished, the external field would divide, but unequally, and the strengths of the two paths of the external field would be inversely as the reluctance of their respective paths. This is only an extension of Ohm's law, that $C = \frac{E}{R}$, applied to magnetism, and may be written $\phi = \frac{M}{\rho}$, where

ϕ = lines of force;
M = magnetomotive force;
ρ = magnetic reluctance.

In Fig. 9 it is shown that in one pole the cross-induction flows through the neck, E F, with the forward induction and against the forward induction in the other pole. If, now, this neck is made of such a cross-sectional area that it is saturated by the forward induction alone, it is evident that there will be great reluctance for additional lines, and consequently the cross-induction will flow in preference through the other pole, with the result that not only will there be a distorted, but also an unsymmetrical field, and the field under horn A will be considerably weaker than that under B, and the field under horn C much stronger than that under D. If then the brushes are set across a diameter of the commutator, it will be impossible to give them such a lead as will give freedom of sparking on both lines, and in order to secure sparkless commutation the brushes must be set across a chord. The bad effects of doing this will be apparent, as the volts induced in coils A and B will not be equal, as more coils will be in series in one set than in the other. A similar phenomenon which will obtain with multipolar machines if all the poles have not the same strength will be dealt with later.

(To be continued.)

BUENOS AYRES.

A long illustrated article, contributed by Mr. William Hulke to the *Elektrotechnische Zeitschrift*, describes in detail the electricity supply works of the Compañia General de Electricidad de la Ciudad at Buenos Ayres.

Incidentally we learn that Buenos Ayres has a population of 780,000 persons, and is supplied with electricity for lighting and power purposes from four different supply stations. One of these, La Primitiva, owes its existence to local enterprise, while a second, the River Plate Electric Company, is of English origin. A third, the Deutsch Ueberseeische Elektricitäts Gesellschaft, was founded by the Allgemeinen Elektricitäts Gesellschaft, of Berlin. The fourth—namely, the station with which we are now concerned—is that owned by the French company first mentioned, which entrusted the electrical work in connection with the undertaking to the Union Elektricitäts Gesellschaft, of Berlin. For the most part, the houses in Buenos Ayres consist of only one storey, and in consequence the town naturally extends over a very wide area, over which the consumers of electrical energy are scattered. The installation of the company in question was put down mainly for the purpose of supplying electricity for lighting, provision, however, being made at the same time to facilitate the connection of motors to the system, besides which the supply of energy for traction purposes had also to be taken into account. Having regard to these circumstances, the mono-cyclic system of supply was adopted. For lighting purposes this system is said to enjoy, in common with the single-phase system of supply, the advantage of easy regulation of the line voltage. It also enables the use of synchronous motors. For traction work the mono-cyclic alternating currents are transformed into continuous currents, synchronous motors direct coupled to continuous-current generators being emp'oyed. But in the future it is intended to instal rotary transformers. There are eight boilers of the Belleville type installed, each capable of generating 66,000lb. of steam per hour at a pressure of 15 atmospheres. In the engine-room are four compound horizontal engines capable of developing 550 h.p. to 770 h.p. each when running at 125 revolutions per

Digitized by Google

minute, or with increased admission 850 h.p. to 1,000 h.p. In addition to Corliss gear and very sensitive governors, provision is made whereby the admission to the low-pressure cylinder may be cut off by hand. To each engine is coupled direct a mono-cyclic dynamo designed for an output of 500 kw. at 3,150 to 3,450 volts terminal pressure, with a frequency of 50. The necessary exciting current at 140 volts pressure for these machines is furnished by two steam dynamos of 30 kw. capacity each, running at 300 revolutions per minute. There is also a motor-driven set installed, consisting of a 30-kw. continuous-current generator coupled direct to a eight-pole three-phase induction motor, designed for a terminal pressure of 230 volts. A second set of similar type has been provided to furnish exciting current for extension plant in course of erection. From the station the current generated is conveyed by means of seven feeders to the primary network of mains, in connection with which latter are 50 sub-stations in which the primary current is transformed down to 230 volts for distribution. Cables of the three-core type are used for the feeders and primary network. The three cores comprising each primary cable are separately insulated with impregnated yarn and paper, then twisted together, and finally protected by a double covering of lead and iron armour. Two of the cores serve to conduct the main current, while the third, of smaller sectional area (about 35 to 40 per cent. that of the lighting cores), serves exclusively for motor load. The secondary current is distributed on the three-wire system, with 230 volts across the outer conductors, each of the three wires being equal in sectional area. The cables are so proportioned that both small single-phase and rotary-current motors may be connected direct to the secondary network. The single-phase motors are self-starting, but to drive one of the small rotary-current motors a single-core auxiliary cable is laid in addition to the ordinary secondary cables to the nearest sub-station, in which a small power transformer of 5 kw. to 10 kw. capacity is installed, this being connected up with the larger lighting transformers. Large motors are supplied direct from the primary network through special transformers. The street-lighting is by means of arc lamps, each lamp being supplied from the secondary mains through a separate transformer, with 13 amperes at 30 to 33 volts pressure.

The accompanying illustrations (Figs. 1, 2, and 3) show the general arrangement of one of the transformer sub-stations. Each of the stations is placed below the street level, the entrance where possible being from the side-walk. In order to economise the secondary distributing cables, the sub-stations are situated near street crossings so far as possible. The walls of each chamber are formed by a double lining of brickwork, with an air-space between the outer and inner linings, the inner surface of the outer lining being, moreover, coated with asphalte.

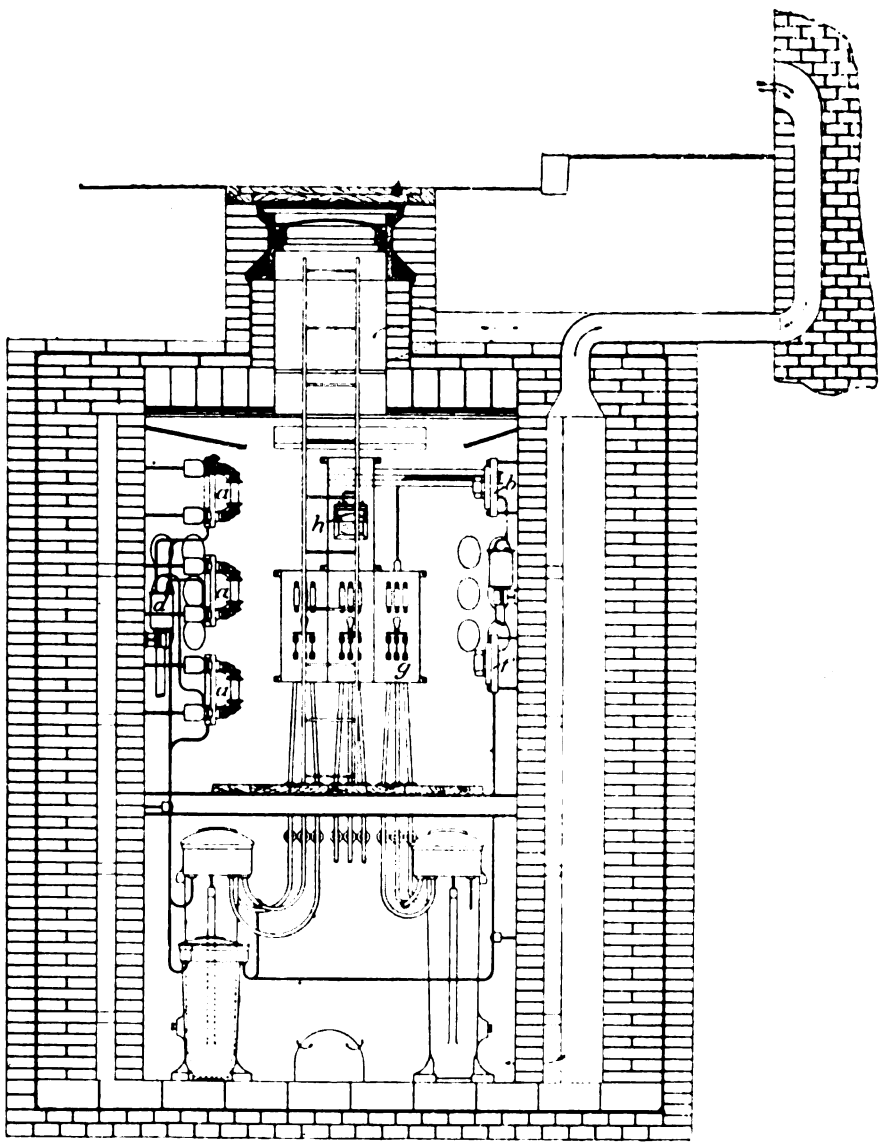

FIG. 1.—Section of Transformer Chamber, Buenos Ayres.

In the case of the sub-stations situated below the sidewalks the covers rest upon two strong I-girders, while in the case of those under the roadway three such girders are provided. Excellent provision for ventilating the chambers has been made as shown. The transformers employed have capacities of from 15 kw. to 30 kw. Their primary and secondary windings are connected respectively to the switchboards, *a* and *b* (Fig. 1). For the primary side three marble panels, *a* (Fig. 2), are provided, each of which carries four or five fuses, *c*. The three conductors from

Digitized by Google

the primary terminal, *d*, of each cable are connected to terminal pieces on the switchboard, and thence connected through the fuses to three 'bus bars, *e* (Fig. 2), which in another small marble panel, *f* (Fig. 1), is placed underneath these panels and provided with a 'bus bar, besides one to three fuses, through which the current is conducted from

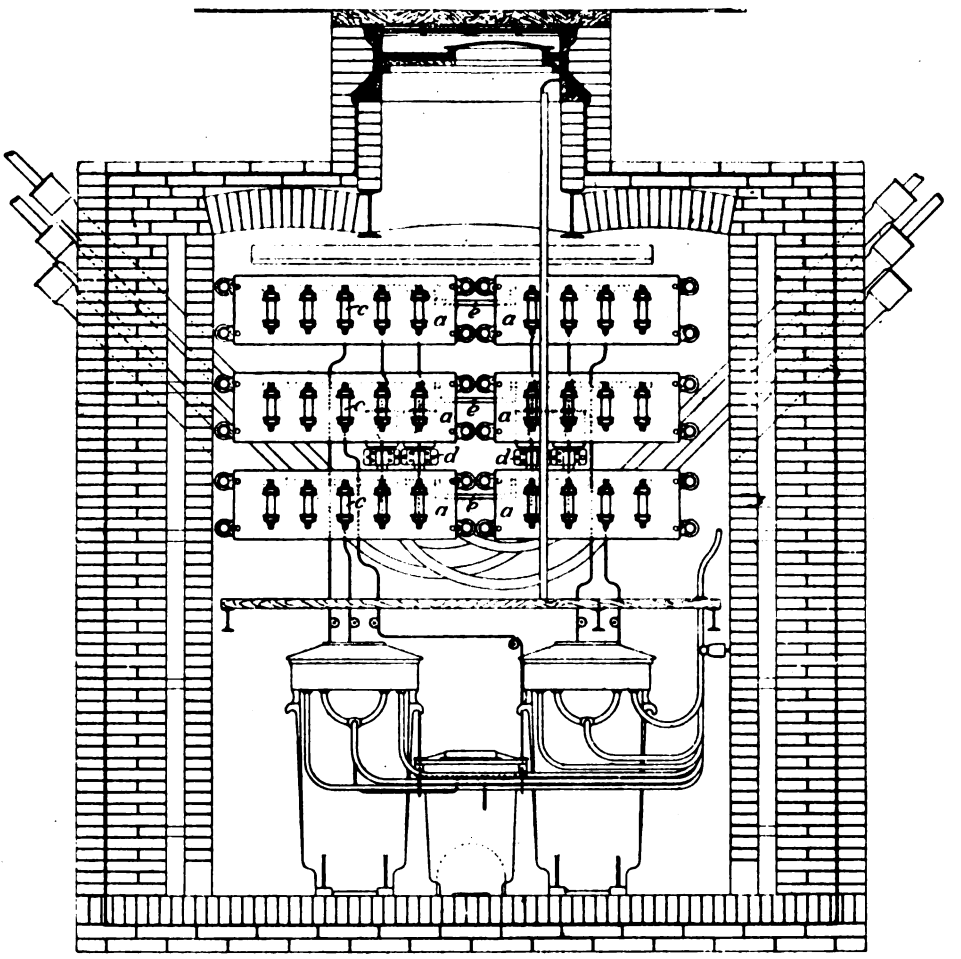

FIG. 2.—Section of Transformer Chamber, Buenos Ayres.

their turn are connected to the corresponding pole of the transformer. Opposite the primary switchboard the secondary switchboard, *b* (Fig. 1), is arranged. This is likewise of marble, each panel being provided with three 'bus bars and 12 fuses, so that four secondary circuits may be connected to each panel. Two such panels placed side by side are the rule, the 'bus bars of like sign being connected in parallel. Where energy for power purposes is required, the auxiliary transformer to the single-core cable mentioned elsewhere.

In conclusion, it must be remarked that the description gives the impression of a very complicated system of distribution—one, in fact, which it would be difficult to reconcile to ordinary conditions. It would be interesting to know the total loss of energy involved by the complicated system of transformers adopted.

AN IMPROVED GLASS REVEALER.

The following is an abstract of a paper read on Friday last by Mr. Bryan Donkin before the Institution of Mechanical Engineers on "Some Observations on an Improved Glass Revealer for Studying Condensation in Steam-Engine Cylinders and Rendering the Effects Visible." The devices described by the author are an improvement on an earlier type of revealer made by him some years ago. As will be seen from the illustrations (Figs. 1 and 2), the revealer consists practically of an extension of the steam-engine cylinders, so arranged as to enable the observer to see whether condensation is actually taking place or not. In the improved revealers the inner glass cylinder is made thinner than formerly, and the connecting pipe between the instrument and cylinder is made of both

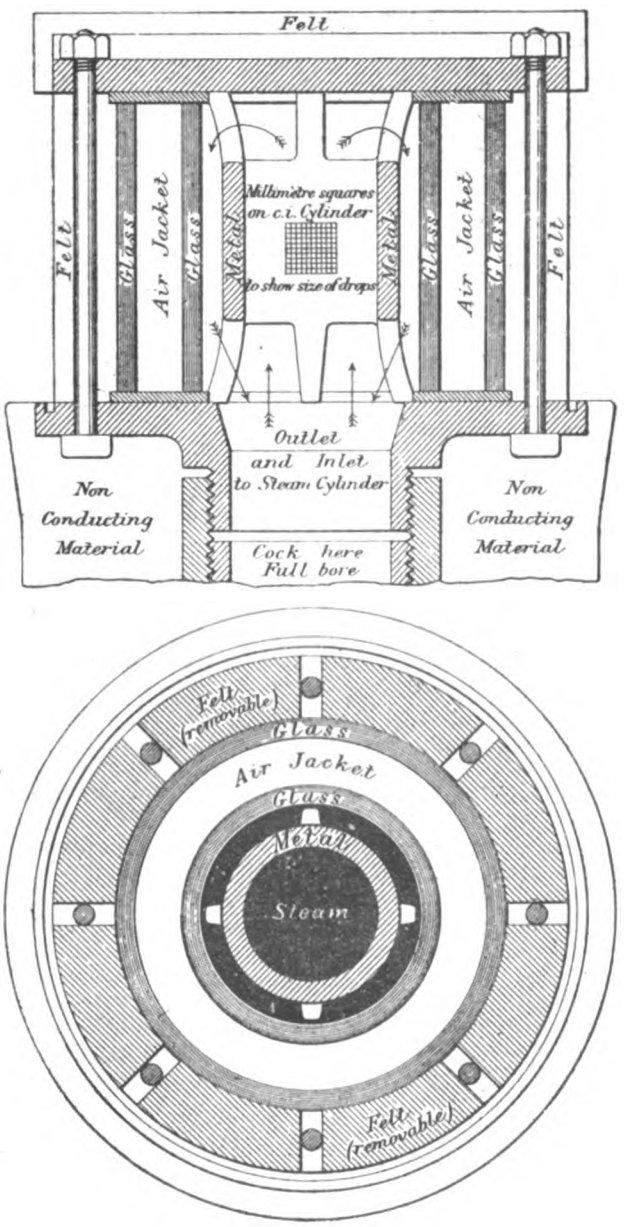

FIG. 1.—Glass Revealer of Steam-Engine Condensation, designed by Mr. Bryan Donkin.

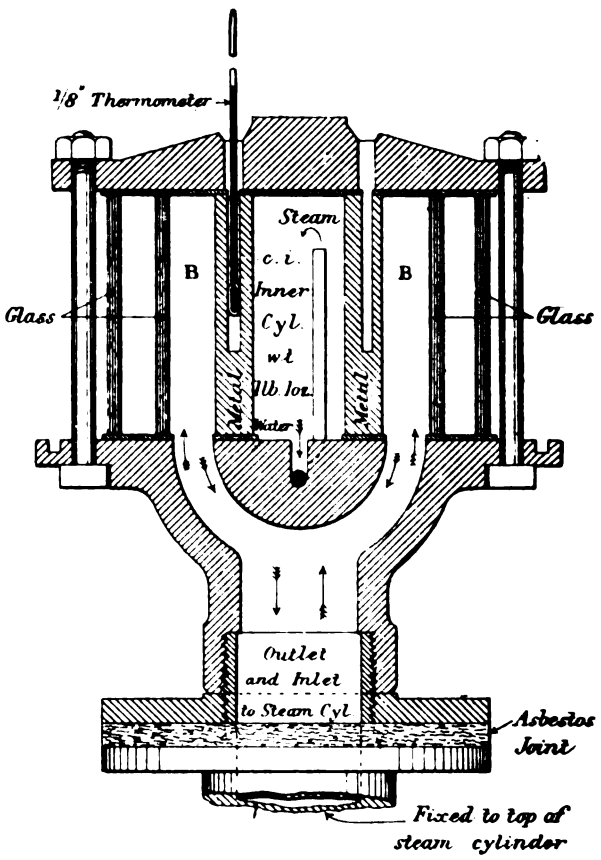
short and straight. This pipe is also made of a large area, and provided with a cock of considerable diameter, so that the connection between the cylinder under observation and the steam-engine cylinder is ample. All the external metal and glass surfaces are well covered with non-conducting materials to diminish radiation, in order that the behaviour of the steam in the revealer may be as near as possible the same as that in the steam engine cylinder. The author thinks that with the precautions he has taken, the effects in the condensation in the revealer may be between 85 and 95 per cent. of the actual truth. The construction of the glass walls of the revealer is such as to enable the condensation to be easily observed and even photographed. These modifications have resulted in the minute globules of water formed on the glass wall being much smaller than with the older type of instrument. When the glass cylinders are properly warmed, the diameter of the globules is from 0·04in. to 0·08in., and even then after working for 10 or 15 minutes the diameter becomes less. Tracing the operations through and commencing with the steam stroke, the first result observed when the steam is admitted to the revealer is a light and not very dense cloud or white fog coming up from the engine cylinder. This is precipitated upon the



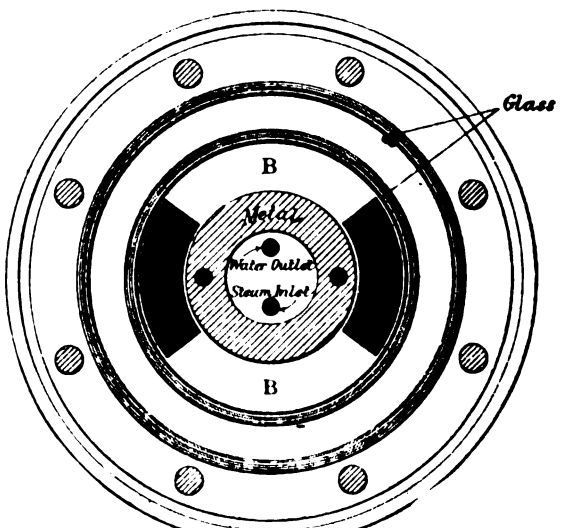


FIG 2.—Another Type of Revealer.

hot internal glass and cast-iron walls, and is seen as very fine globules or particles of moisture or condensation. This cloud is sufficient to obscure a light placed on the opposite side of the revealer. Re-evaporation then rapidly follows before the end of the steam stroke. On the opening of the exhaust valve the cloud passes quickly off into the cylinder, and the glasses become quite transparent. A good illumination renders the incoming and outgoing clouds of mist quite visible. Each time the steam enters, a large number of very small globules, at about equal distances from each other, are immediately seen upon the glass walls. These are from 0·002in. to 0·0016in. in diameter, or less, and are distributed in a fairly uniform manner over the surfaces. The time occupied by

Digitized by Google

the deposition of the globules, and their re-evaporation, is perhaps a tenth of a second. Before the end of the steam stroke, the duration of which is about half a second, and before the exhaust valve opens, the smaller globules, $\frac{1}{25}$mm.

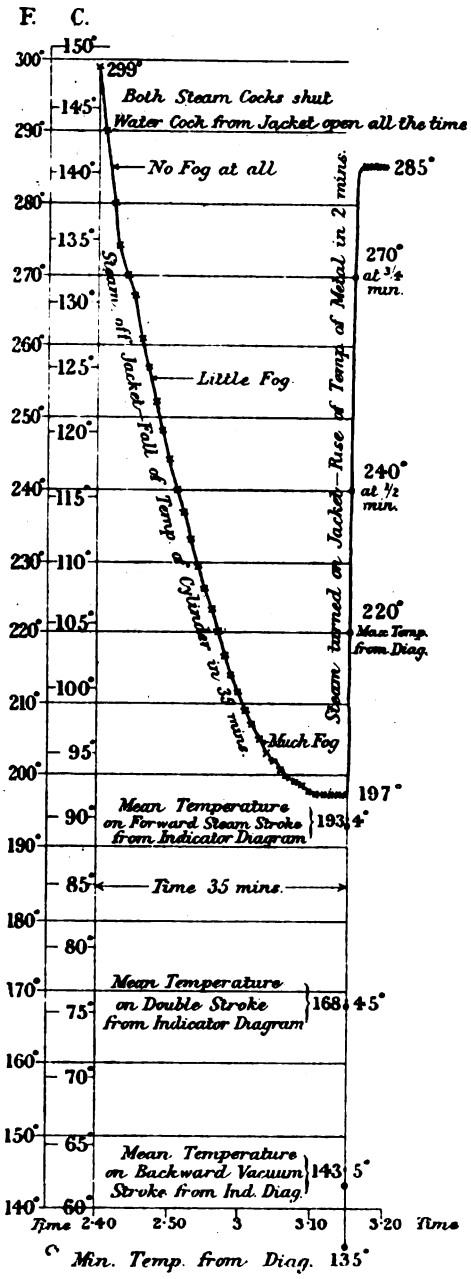

FIG. 3.

in diameter, are all evaporated. During the exhaust stroke the larger globules are also re-evaporated, but not so quickly. The internal surfaces are sometimes quite dry, and at other times a few drops of moisture remain on them. To facilitate the study of these minute condensed globules or wet particles on the inside of the inner glass, a microscope is used, and the glass and iron walls well illuminated.

The author concludes that the size of the globules is determined by the difference of temperature between the walls and the steam, and this is supported by the experimental evidence obtained from comparing the action of the revealer when placed on the low-pressure cylinder and a high-pressure cylinder of a compound engine. The globules, when the revealer is placed on the high-pressure cylinder, are much larger. Artificial cooling of the cylinder produces the same result. In order to obtain the exact diameter of these globules, cross lines, vertical and horizontal, were marked across the cylinder, as seen in Fig. 1. The observations obtained also show that the idea is not feasible, that there can exist a thin film of condensation water on the internal surfaces of steam-engine cylinders, as with a very wide range between the temperatures of the walls to the working steam the deposited moisture is still in the form of globules.

Another development is illustrated in Fig. 2. In this a small cast-iron cylinder is fixed in the centre of the revealer, and so arranged that boiler steam can be introduced inside it to raise its temperature, provision being made to drain the water away. Cold water can also be passed through it continuously to reduce its temperature. The mean temperature of this inner cylinder is taken by means of a mercurial thermometer about 2½mm. (0·1in.) in diameter, placed in a hole in the centre of the wall. The steam from the engine cylinder passes at each stroke into and out of the annular space, B B, between the cylinder and the inner glass. The fog or condensation on the walls can be observed through the glass cylinder by the eye or a microscope. In this way the cylinder can be either heated by steam or cooled by water, and the fog effects noted for different temperatures of the small cylinder inside the revealer. To get the mean temperature of steam in the steam-engine cylinder, indicator diagrams are taken, and the mean temperature calculated from the pressures. Thus, when all the conditions are constant, the temperature attained by the inner cylinder can at any time be compared with the mean temperature of the steam touching its walls.

The author proceeds in his paper to describe in detail experiments which were made with these instruments in December, 1899, and May of the present year. We have not space to describe these experiments in full, but his interesting conclusions are as follows: In spite of any deposit of moisture on the cast-iron surfaces of the cylinder, the heat-absorbing properties are always greater than the heat emission to the exhaust. The experiments also point to there being no interference caused by water on the surface of the cylinders to the passage of heat from the cast-iron cylinder walls. Some experiments on the radiation which take place from such an instrument when connected to a steam-engine were also made. The results of the experiments are given in tabular form and are handy for reference. At the end of the paper there was also read a communication from Mr. Nadal, an Ingenieur des Mines of France, whose experience has been considerable with this class of experiment. He confirms Mr. Bryan Donkin's conclusions and adds some most interesting figures of his own. Amongst these we notice that he calculates from experimental data that the wet metallic surface of a certain revealer was able to observe 36 calories per square foot per second per degree Fahrenheit difference in temperature between the steam and the metal surface in contact with it. On the other hand, the emitting power of the dry metallic surface calculated in the same way is only about 0·1 calorie.

SOME REMARKS UPON A HITHERTO UNRECOGNISED PLANETARY LAW.

BY R. C. SHETTLE, M.D.

In a treatise which I published in 1897, entitled "The Origin of Matter and Force," I pointed out that matter took its origin in the quantitative condensation of an original, unformed stuff, or eogen, having eqnal density throughout its mass; that the quantity in each condensing unit gave origin to the physical properties of matter, and that the uncondensed residuum of this original stuff constituted the ether, some of it pervading all space, some of it being condensed upon the surfaces of the formed units by the attractive force which they, as matter, necessarily exercised. Having thus shown the basis upon which my superstructure rests, I proceed to demonstrate the existence of a great planetary law, under the influence of which work was done upon the earth, changes of temperature were effected, its solid surface became clothed with grass, and its waters so associated with the more solid matter as to bring forth animal entities according with the nature of primary combinations or germs.

I assume: (1) That the earth consists of a vast number of minute units of various forms of matter aggregated under the influence of gravity, with eogen condensed upon the surfaces of the material molecules. (2) That the space which exists between the units of a molecule, between the molecules themselves, or between the larger units of the celestial system, is occupied by primary stuff or eogen, differing only in degree of attenuation. (3) That the earth, previous to its surface being covered or inhabited by various forms of vegetable and animal life, had essentially a bare, rugged surface, and was of oblate-spheroidal form—a form produced by its axial rotation. (4) That the earth's surface, in addition to biological formations, is covered with an atmosphere of finely-divided particles of matter, the density of which is regulated by the laws of gravity. (5) That the changes effected in material conditions and modifications of stress by the motions of the earth, in connection with its solar and planetary relations, give rise to all terrestrial phenomena.

My present aim is to show that the sun and the earth, or other planets of like material condition, so act upon each other and upon the residual eogen or ether as to reveal a very important planetary law, determining the particular mode in which phenomena are produced, either upon the planet's sunward surface or in its atmosphere, or generally, whereby light is evolved, temperature affected, and inorganic matter converted into a form adapting it to the requirements of the vegetable and animal kingdoms of Nature.

The law to be recognised may be stated as follows:

1. The sun and its planets rotate axially in the same direction in a vast ocean of ether. It is assumed that the rotation of each, in proportion to its mass motion, causes the ether to move in the same direction, thus creating an ether vortex around each rotating mass.

2. As the axial rotation of the sun and planets is in the same direction, the effects of the dominating solar vortex upon the planetary vortex must vary, according as the two vortices take the same, or oblique opposite directions, on opposite sides of the planet; for whilst on the dark side of a planet the two vortices are in the same direction, on the sunward surface of a planet the direction of the solar vortex is opposed to that of the planetary.

3. The character of the work done, or, in other words, the nature of the phenomena evolved upon a planet's surface, varies with the relative direction and intensity of the two ethereal vortices, these being more particularly determined by the position of the planet in relation to the sun.

To accomplish my object, it is necessary to somewhat precisely define the material conditions and the means by which work is effected, phenomena appear, and the law is manifested. The material conditions are as follows: (1) there is the sun, the prime centre of our planetary system; (2) there is the earth, with its atmosphere; (3) there is the residual uncondensed eogen or ether. The forces employed are: (1) The direct stress of solar terrestrial density—*i.e.*, gravity; (2) the vortical or suction force (due to rotary or other motion of the sun and its planet), which each mass of matter, in proportion to its extent of condensation, or its density, exercises upon the ether in accordance with the affinity of matter for ether previously mentioned. The general results of these material conditions, and the forces generated by motion, are, perhaps, better realised by confining attention: (1) To the sun as a material unit rotating axially in a vast sea of ether, which ether is undergoing vortical motion under the suction stress of the central body. (N.B.—The ether of the solar system now being considered is supposed to be similar to that originally extending throughout the space within which the sun and the various units of the material universe were formed). (2) To the consideration that the earth and other planets or units of the system by their rotation are creating other vortices (each in proportion to its magnitude and motions) in this same solar ocean of ether. (3) To the fact that as the axial rotation of each secondary unit is in the same direction as that of the sun, the interference with that part of the great primary vortex motion caused by the sun which each planet encounters will depend upon the mass motion of each planet, the density of its atmosphere, and the relation which it bears to the sun.

It will be well to state how these forces stand related to each other, and to the matter with which they are associated under variations of distance.

1. *The Direct Solar-Terrestrial Stress of Gravity.*—This has two sources of origin: (1) solar; (2) terrestrial. Gravity is known to exercise an attraction in proportion to the product of the involved masses divided by the square of the distance. Consequently, as the intensity of the attraction decreases in proportion to the square of the distance from the body creating it, the intensity of the stress, which may be regarded as emanating from the centre of any mass, is vastly greater on the surface of the body originating such attraction than on the surface of the distant body affected. The effects of solar-terrestrial gravity, nevertheless, determine certain definite relations in the intensity of gravity acting on the surface of the earth, as, for instance, in the case of the tides.

2. *The Vortical, or what may be called Suction Stress.*—This is the direct effect of suction upon outlying ether. But it must be remembered that as the two bodies severally exercising force are in motion, there is the resultant of two elements—viz.: (1) the static (identical with gravity), and (2) the dynamic, due to the earth's motions. The intensity of both varies. The resultant is essentially a force which took its origin in variations of density, coupled with varying rates of motion, and its tendency is to restore equilibrium and rest.

Confining attention now to the earth and its influence upon the solar vortex, and to the influence of the solar vortex upon the earth, we see that every change in the relative distances between the two bodies must be attended with varying results, both with regard to motion and to influence on the surface of our planet. To rightly estimate these effects, it will be well to consider the variations as due to the greater or less proximity of the earth to the sun in its orbital path, as shown by Kepler's second law. Kepler's second law runs as follows: "The areas described, or passed over, by the radii vectores of a planet round the solar focus are proportional to the time taken in describing them." In other words, *the planet moves faster as its distance from the sun diminishes*, its greatest proximity being in mid-winter of the northern hemisphere.

Now, at first sight, this law appears to upset all that we are taught about the solar origin of the phenomena of heat and vegetable and animal life, because temperature is highest in the middle of summer, and in the northern hemisphere the processes of vegetable and animal life are carried on with greater activity during our summer months, when the earth is most remote from the sun. We must remember also that the northern summer corresponds to the southern winter, so that changes in the earth's distance from the sun at different times of the year cannot be the only, or, in fact, the chief agents in the production of the seasons. These apparent anomalies have been ascribed to various causes. It is inferred that the greater amount of energy (heat, light, etc.) manifested in summer time is due to the fact that the sun's influence is more direct or vertical in the equatorial regions. Unquestionably the relative positions of the sun and the earth in that, as in other respects, must be important factors in the evolution of the phenomena in question, but not, I venture to think, as generally explained—viz., that the heat transmitted as energy only through intermediate space reassumes the form of heat only when it impinges upon the earth. The present statement of facts will, it is believed, go far to prove that the doctrine of "conservation of energy" applies most completely to the sun as well as to its planets and the evolution of their phenomena, under which there is practically no loss of energy; but, on the contrary, that the increase of heat, and increased biological activity during our summer, are due to work done upon the earth's surface *under a certain balancing, blending, or counteracting of the solar-terrestrial vortical forces* more especially originated by mass rotation at the time when the northern hemisphere of the earth is more particularly exposed to the influence of the sun. It is difficult to precisely define the part which each element of force exercises in effecting axial rotation of the earth, because both density and vortical forces appear to have an important influence in its production, and in maintaining the earth's orbital motion.

As the distance between the earth and the sun is increased by about 3 per cent. at the June solstice, the intensity of the solar vortex, diminishing inversely with the square of the distance, will be slightly reduced; but at the same time the northern pole and hemisphere of the earth are being every day more fully exposed to the influence of the solar vortex. The intensity of the earth's vortex (the product of its own motion) is constant. It is then evident that, as the earth recedes from the sun, the relative intensity of the forces must be proportionately changed. And as the two forces are acting in opposite directions, or nearly so, upon the atmosphere and

Digitized by Google

surface of the earth, the deduction appears to be justified that the work done upon the sunward surface of the earth is due to the resisting influence which these two obliquely vortical forces, acting in opposite directions, exert upon each other and upon the molecules of terrestrial matter, when neither force can entirely overcome the other. The results appear: (1) in increased molecular motion generally, of which rise of temperature, or heat, is the measure; (2) in proportionately increased biological activity, growth, stimulus, etc., but as all these phenomena are more or less intimately associated with molecular motion, even if not absolutely dependent upon it, the molecular motion may be said to cause increased vital activity, and thus their intimate relations to solar stress are clearly traced. *Note.*—The same general principle applies to the solar system of planets. A planet has its form, its orbital and other motions, as well as its special phenomena determined by the character of its component matter, upon which its density and its solar attraction depend. The earth as a planet is spinning upon its axis like a top, but whilst the temporary motion of the top has resulted from the rapid unwinding of the string, the sun's pull upon the earth is continuous. How this affects the motions of the earth will now be dealt with, as well as the precise manner in which "nutation" results from the action of stress.

The forces concerned exercise two distinct forms of pull: (1) That from density, more or less direct from its origin in one mass to its action on the other. (2) That from axial rotation, giving rise to vortex motion, whose strands, or limbs, or areas of diffusion are ever widening according to a well-defined law, and the confines of which, as already stated, when of solar origin extend far beyond the area of the solar system; while vortex motions of planetary origin become lost, or merged in those of the greater power, as they become enfeebled by distance or are associated with those of the sun.

The sun and the moon are doubtless the two bodies whose influence more particularly determines the axial inclination of the earth, for, owing to the moon's proximity, such axial inclination must certainly be somewhat modified by that luminary. At the present time, however, it will suffice to state that the *axial* inclination of the earth is due to the density

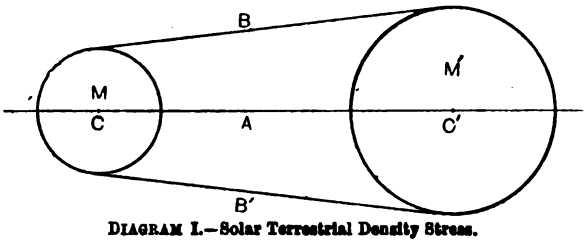

DIAGRAM I.—Solar Terrestrial Density Stress.

stresses of the various bodies with which it is associated, and that its orbital as well as its axial motions are the effects of the vortical motion of the ether induced by the sun. The modification of that motion by vortical force of lunar origin may be considered further on.

Two diagrams are given to represent the influence of mutual static and dynamic forces upon two opposite bodies and upon the intermediate ether. No. 1 shows solar-terrestrial *density*, or gravitational stress, in a static form. No. 2 is intended to represent the two bodies, M and M', rotating axially, and, by their axial rotation, throwing the surrounding ether into vortex motion. In both I. and II. the centres of the stress-creating bodies are at C and C', and the line A which passes through C and C' marks the line of the greatest intensity. This stress diminishes laterally towards lines B and B', where it ceases (Diagram No. I.). With regard to the static effects of the density stress of the masses, it is only necessary to state that each mass attracts the other in proportion to its mass and inversely as the square of the distance.

Turning now to the vortical motion of the ether as originated by each mass, Diagram No. II. graphically represents the direction of the stress induced by the suction force of the two axially rotating bodies. This rotation around C' is indicated by the arrows D and D', and around C by the arrows *d* and *d'*. Each body in proportion to its density is acting like a suction engine upon the surrounding ether, because the central force of cohesion under which matter was formed far exceeds any external force which can be brought to bear upon it to tear the matter asunder. It necessarily follows that each mass, in proportion to its mass when thrown into motion, tends to impart that motion to the surrounding ether, and the vortices in the ether become thus a natural sequence of axial rotation. The direction of these vortices of the ether is shown in Diagram No. II. by arrow points on the lines S, S^1, S^2, S^3, and E E, the lines S having solar and the lines E terrestrial origin. The intensity of the vortical forces, like gravity, is, of course, greatest at the seat of origin, and diminishes inversely with the square of the distance from that seat of origin, and in relation to the work done by solar vortices upon the mass and surface of the planet, as we recede from the sun and approach the planet *the intensity of the solar vortices diminishes and the intensity of the terrestrial vortices increases.* The solar vortex emerging from the sun acts upon the surrounding ether until this reaches the earth's atmosphere, when owing to the great affinity of ether and matter, the ether seizes upon the particles and tends to drag them in the direction of the solar vortices marked S. But the vortical motion created by the rotation of the earth has now to be dealt with, and this tends to carry the atmosphere with it. By reference to Diagram No. II. it will be seen that at *d'* on M, these solar-terrestrial vortical forces on the sunward surface of the earth act and react upon each other obliquely in more or less opposite directions. In doing this the particles of matter are rotated axially, provided the intensity of the two opposite forces is sufficiently balanced. But as the work done upon the earth appears to be most intimately associated with the adjustment of their potentials, the mode in which this is effected requires to be very clearly shown; more especially as the normal rotation of every unit of matter (of any dimensions) appears to be accomplished upon the same principle. At the same time the mode in which current electricity (or current ether) acquires its helical direction will be described.

It will be recognised (1) that as each mass is rotating axially whilst immersed in the ethereal ocean, the stress due to the density of each mass is drawing the ether through, and out of the other (see Diagram No. II.); (2) that the axial rotation of each mass in an inclined plane which is not coincident with the plane of the ecliptic, determines that the ether current should acquire the helical direction as it passes through the two stress-creating bodies, because each mass, by the inclination of its axis of rotation, imparts leverage, screw or helical motion in relation to stress. The mode in which these helical currents of ether, or electricity so-called, are caused to assume a right and a left hand direction has now to be shown. The terms right and

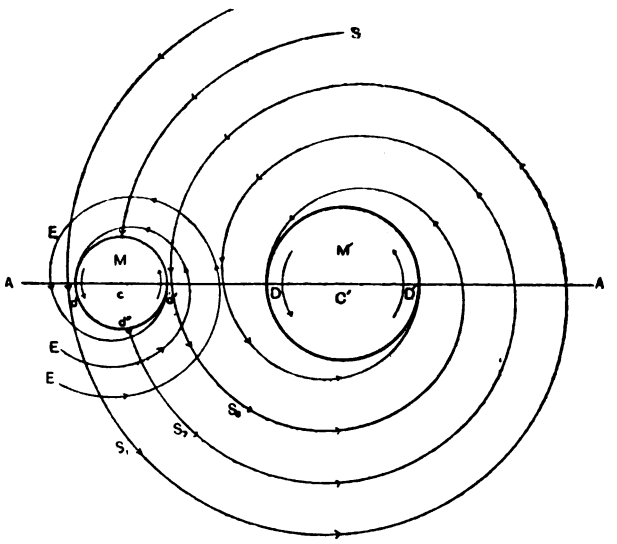

DIAGRAM II.—Solar and Terrestrial Vortices.

left hand direction imply a point of departure from which the lines take opposite directions. With respect to the earth and the sun, this occurs at a point on the earth's surface at which the sun is directly overhead, and if the observer imagines himself standing upon such point with his face directed to the west, and his two arms extending to the north and to the south respectively, he will perceive that the axial rotation of the earth originates right-hand helical currents proceeding towards the north pole, and left-hand helical currents towards the south pole—*i.e.*, that solar stress currents will pass over and through the northern hemisphere in a right-hand helical direction, and over and through the southern hemisphere in a left-hand helical direction, and in so doing will give rise to the phenomena of north and south polarity; in fact, *the normal magnetic polarity of the earth will be established thereby*, whilst the magnetic potential of the earth will be determined by the quantity of helical current energy, which, in consequence of the earth's rotation, traverses the mass at any given moment. (3) It will be observed that as the sun and the earth are both rotating axially in the same direction, the vortical currents created by such rotation are of the same helical denomination in both bodies, whether above or below the equator in either body, but the twist would be more extended in proportion to their mutual relations—*i.e.*, when moving round a sphere they would take the circular course, and exhibit phenomena resulting therefrom; but after leaving the mass, they would become more extended and linear under centrifugal force, and the phenomena would be proportionately modified. The influence of particular helical currents upon other helical currents of the same and of opposite direction must now be considered.

The influence of helical currents is all-important in the evolution of certain natural phenomena. In the laboratory

Digitized by Google

right and left hand helical currents and the attendant phenomena may be reversed at will. A right-hand helix may be changed into one of left-hand direction, or *vice versâ*, *absolutely proving* that the phenomena of positive and negative electricity, or of north and south magnetic polarity, are partly due to the direction of the moving ether. Perhaps the most ready and simple method of realising the effects of these helical ether currents upon each other, and on the matter with which they are associated, is to wind two rather stout wires round a ½in. rod, one in a right and the other in a left hand direction; then, when the rod has been removed, to divide each helix into two equal portions by cutting it across its length. There will then exist two right and two left hand helices, and taking them as models of electric currents, the effect of such currents, when acting upon each other under various relations and directions, may be ascertained. Thus, if one right-hand helix be placed end on to another right-hand helix, they may be readily screwed into each other, and so the force of attraction (other things being equal) will be in proportion to the number of helices acting upon each other from the same direction. This represents the forces engaged in the production of the phenomena of magnetic attraction. The same principle applies to the two left-hand helices. But if a right-hand helix be placed end on to a left-hand helix and similarly moved, the two terminals of the wires will act in oblique and opposite directions upon each other. This represents the conditions when a pair of *like* magnetic poles are brought together, and is representative of magnetic repulsion and of the phenomena shown by iron fillings scattered around like magnetic poles. Such facts render the somewhat complicated mutual influences of helical forces less difficult to understand.

The points which have been established are as follows: (1) That the sun and the earth, or any two distinct forms of matter, owing to their density, are mutually exercising stress upon the intermediate ether as well as upon each other. (2) That by their axial rotation, and in proportion thereto, they are creating vortical motion in the surrounding ether. (3) That axial rotation of each body upon an inclined plane causes the currents of ether which pass through the two bodies to assume helical directions. (4) That the sun and the earth, owing to the currents of ether moving in and around them, act as two magnets placed nearly parallel to each other, with their two north poles pointing in one direction and their two south poles in another. Although there may be great disparity in the sizes of the sun and of the earth, the north pole of one tends to repel the north pole of the other; and as the same principle applies to the south poles, each body, in proportion to its mass and the helical currents moving in it, tends to maintain the vertical position of the other. (5) That, speaking generally, the amount of the work done by the sun upon the mass of the earth under the influence of these forces varies with the distance between the masses.

It is now necessary to describe the nature of the work done by these forms of solar stress upon the earth during both winter and summer solstices, and to show how the effects differ under variations of distance. Subsequently I shall endeavour to define the cause of the earth approaching the sun from shortly after the June solstice until it has attained its greatest proximity in the beginning of January, and of its receding again from the sun from the beginning of January until shortly after June 21.

1. *The December Solstice.*—During the December solstice, when the earth's proximity to the sun is greatest, the intensity of solar stress, of both static and dynamic forms, is also greatest, and the principal effect of solar force is at such time increased velocity of the earth's orbital motion, with accompanying phenomena. These effects are the direct result of the increased surface density occasioned by the intensity of the solar vortex forces repelling, or driving back on to the surface of the earth, the vortex forces originated by its own motion. An inspection of Diagram No. II. will show how this is brought about. Thus, as before stated, at d' on M the solar terrestrial forces are shown by the arrows to be acting in opposition to each other, and in consequence of the disproportion in the intensity of the two forces, that of solar origin being much greater than that originated by the earth, the terrestrial forces are concentrated upon the surface of the earth, and the friction between the two vortices (solar and terrestrial) is increased in proportion to the pressure exercised. The earth's orbital motion is also most rapid at this time. It must, however, be remembered that the *temperature* effects due to the changing distance of the earth from the sun in different parts of its orbit will be dominated by the effects produced by the inclination of the axis, as this determines which hemisphere will be most exposed to the solar vortex at any particular time. The effects of difference in the intensity of vortical forces may be illustrated by the phenomena of magnetic repulsion. Thus, if two north poles of unequal potential are placed together, allowing a small space between them, and the north pole of a smaller magnet be introduced into this space, it will take up a position which is *not* midway between the two bars, but is nearer to the *weaker* one. This same principle of action is shown in the case under consideration, by the intensity of the solar vortices repelling and pressing the terrestrial vortices on to the surface of the earth. Again, at d on M (Diagram No. II.), at the dark side of the earth, the solar and terrestrial vortex forces are seen to be acting in the same direction, and as a consequence they combine to promote accelerated orbital motion of the earth, and also by pressure to prevent molecular motion. It will be seen by looking once again at Diagram No. II. that each of the lines of force, S (1, 2, and 3), tends to promote motion of the earth in its orbit: (1) is acting, as already shown, in the same direction as that of the earth's rotation as well as in the direction of its orbital motion; (2) is giving a direct pull in the direction of orbital motion, or nearly so; and (3) is pulling also in the same direction, but in opposition to the axial rotation of the earth. Of course, the intensity of each of these pulls will vary with the distance from the sun at which they are exercised upon the surface of the earth's mass, therefore the pull at d' exceeds the pull at d and at d'', but the orbital motion appears to be maintained mainly by the direct stress of density which imparted the axial inclination to the mass of the earth, and in so doing created motion in a definite direction. These appear to be the principal material conditions for the phenomena which characterise the December solstice.

2. *The June Solstice*.—This, or more exactly 11 days later, is the epoch at which the earth is most remote from the sun. Our theory involves a reference of phenomena experienced on the sunward surface of the earth to the mode in which solar and terrestrial vortices of force act and react, and so work upon each other and upon the molecules of matter with which they are associated under a certain and definite equilibrium of these forces without appreciable loss of solar energy. The mode of producing phenomena may be explained as follows: The fact that the earth's axial inclination is maintained by the density stress which each mass of the solar system exercises upon it is unquestionable; and it will be readily seen that the same principle applies equally to all the earth's component molecules, both throughout its mass and in its atmosphere. Therefore, it is that each of these molecules is held in a definite position, whilst it is subjected to the influence of helical lines of stress both from the sun and the earth. The general principle by which axial rotation of the molecules is set up and maintained by these solar terrestrial vortical forces when evenly balanced has been stated. Attention has also been directed to the fact that these vortical forces are not only capable of driving other weaker forces back upon themselves, but also of causing them to reverse their direction; consequently, in the December solstice, the vortices of terrestrial origin are driven back upon the earth, but now at the June solstice, as the distance from the sun is increased, the solar force is diminished with all its resulting effects, and the earth's orbital velocity is reduced to its minimum value. We must again point out that the dominating cause of the changes of the *seasons* is the inclination of the earth's axis, which causes the northern and southern hemispheres to be alternately more exposed to the effects of the solar vortex. *Temperature* effects due to the earth's changing distance, though really existent, serve only to modify this. But whilst disparity in the intensity of solar-terrestrial vortices is the cause of variations in the velocity of the earth's orbital motion, we have to acknowledge variation of distance as one element in producing the varying velocity.

We have also to consider the gradual changes in the position of the earth's axis of rotation, for it has been recently shown that the position of the mechanical axis of the earth varies slightly within the mass of the earth itself, and this in addition to the slow but constantly progressive conical motion of the axis which gives rise to the precession of the equinoxes. I conclude that the fundamental cause of these important modifications in the rotation of the earth is some slight departure of the earth's centre of gravity from the centre of figure or form. The usual method of referring the cause of precession to the earth's equatorial padding or protuberance only, and regarding the spherical globe of the earth as considered without this padding as absolutely unaffected by the causes which produce precession, seems to ignore the inequalities of structure and density which must exist within the mass of the earth itself.

Natural phenomena appear to favour such a conclusion, and the opinion is supported by phenomena observed when various forms of matter are suspended in the "field" of an electro-magnet, when every form of matter exhibits a characteristic axial inclination as the resultant of the mode in which each substance deals with the lines of force, or the force with the substance. Under such circumstances, since the same law applies to the largest celestial bodies as to the units of which they are composed, the deduction appears obvious that the source of these very important phenomena is to be traced to some slight deviation of the physical centre from the mathematical centre of form as described above. The seasons are connected with the difference in the length of the day and night, and variation in this has naturally been traced to the position of the earth's axis with respect to the sun. The movement of the axis of the earth generates an imaginary cone whose apex is at the centre

Digitized by Google

of the earth, and produces the "precession of the equinoxes" without modifying the inclination of the axis to the ecliptic. This complete movement is known to be accomplished in about 26,000 years. Its effect is to make the solstices occur at different parts of the earth's orbit. "Nutation," or the so-called "nodding" motion of the poles, or axis of the earth, is effected in about 18⅔ years. Changes in axial direction are slight; the maximum does not reach 10″ of arc. The movements of rotation and translation round the sun, with their effects, are simultaneously carried on by the earth; it will therefore be perceived that all these important changes in the earth and its surface condition are brought about by some modifications of the motions of the earth and of its position, and particularly of the direction of its axis, with respect to the sun. But the question has not been answered as to *what gives origin to these changes of axial direction*; and as they are all performed with mathematical regularity, they ought to be traceable to a definite cause. From what is involved in this "scheme" of the universe, I venture to propound the following—viz., that it is due to some more or less *slight* departure of the earth's "centre of form," or mathematical centre from the physical centre.

The solar-terrestrial vortical forces have, it appears to me, many very important offices to fulfil in the evolution of natural phenomena over and above the influence which they exert upon the motions and temperature of the earth. By reference to Diagram No. III. it will be observed that they are always crossing each other, and it would appear that they not only do this, but that they form two helical currents which move from opposite directions one within the other, upon the same plan as in the induction electric machine. In referring to that method of originating

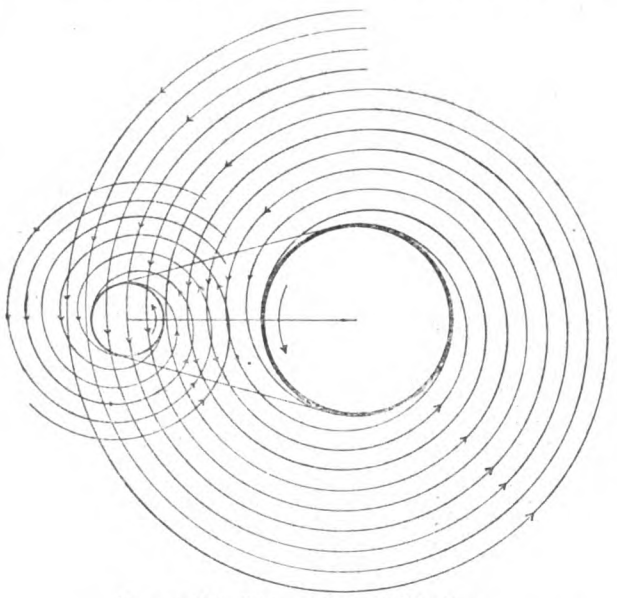

DIAGRAM III.—Solar and Terrestrial Vortices.

currents of electricity in my paper in the *Electrical Engineer* for Aug. 24, 1900, I have shown that these currents rotate and polarise the atmospheric particles with which they are associated, and so originate the phenomena of light. Unquestionably, as it appears to me, they are intimately associated with all the particles in the crust of the earth which they tend to rotate and combine in proportion to their freedom of motion. If this be so, they tend to maintain biological phenomena, and, the primary germs having been supplied, they would determine the conversion of suitable pabulum into the sap of vegetable organisms, or the various forms of mineral and other matter into the blood corpuscles of animal life, in accordance with the character of those primary germs; the shape of the corpuscles testifies to the rotary motion which they have undergone in the process of their formation.

The formation of the individual atoms of the chemical elements is also to be ascribed, according to the views set forth in this paper, to the quantitative condensation of the original eogen while undergoing rotation, the "atomic weight" of an atom depending simply upon the quantity of eogen condensed during its formation, and the physical and chemical properties of the atom depending partly upon the layer of "bound ether" condensed upon its surface, and partly upon the form which the atom acquired during rotation by which the conditions and degree of condensation were governed. In this way, it is suggested, the properties of different kinds of mineral matter originated. Nor does it appear to me that the mode in which the inorganic earth became clothed with grass and inhabited by animal forms is much more complex, provided only the same principle were active in these other kingdoms of nature. Thus in the mineral kingdom the great simplicity by which a pure fluid primary stuff was converted into the several different forms of matter has been noted. Possibly by allotting to each germ the power of taking to itself a certain and definite quantity of each requisite form of mineral matter, the whole conjointly under the influence of solar-terrestrial forces, would possess characters determined by the quantity of each form of mineral matter, and by the nature of the structure into which that matter was wrought.

The steps of the entire process by which this is brought about may be clearly stated: (1) Each mineral unit has its own specific character and polarity, the direct lines of solar-terrestrial stress causing the polarity to assume a direction more or less parallel with such lines of stress, and with the stress proceeding from other units with which it is associated; at the same time the solar-terrestrial vortical forces, acting upon the principle of the induction whirl electric machine, as previously explained, rotate the unit under consideration. This principle applies to the formation of all kinds of mineral matter. (2) But each biological germ is compound in its nature—*i.e.*, several forms of mineral matter enter into its composition; consequently the polarity of the biological germ, which in the seed shows itself more especially in the relative direction of the radicle and plumule and other vital properties, is the resultant of the polarity of all the mineral units; and it is under the influence of solar-terrestrial vortical forces that changes are effected in their material condition, and a new line of polarity is set up, which is the resultant of the polarity of each and all the mineral constituents, and results in the polarity of the so-called germ cells, or biological units.

This, as it appears to me, was the method of creation by which the earth brought forth grass and various forms of animal life. But precisely the same regulating influence as to the quantity of each kind of matter adapted to each description of germ was essential to their complete formation, as in the case of the separation of the primary stuff into definite quantities for the formation of the different kinds or species of mineral matter. It should, however, be added that the process was, in all probability, progressive, and that whilst we are now regarding, in both vegetable and animal kingdoms of nature, the germs as being formed under most favourable conditions it was otherwise at first, the ultimate change being effected by a higher grade of evolution. This does not, however, modify in the least the intrinsic character of the biological germs which would be dependent initially upon the quantity of the respective mineral substances in each, although it would necessarily considerably affect the conditions under which the germs existed.

It is perfectly impossible in a paper like the present to do more than just touch, in the briefest possible manner, upon the far-reaching effects of these vortices of force; but the material universe itself seems to have been brought into existence, in the manner I have attempted to define, by rotation (and condensation) of the primordial eogen, and subsequently the same characteristic form of energy appears to have been utilised by the Creator in the maintenance of that universe in its entirety and harmony.

FORTHCOMING EVENTS.

FRIDAY, OCT. 26.

Physical Society.—At 5 p.m., at Burlington House, exhibition of experiments illustrating certain phenomena of vision, by Dr. Shelford Bidwell, F.R.S.; and papers on the "Concentration at the Electrode in a Solution, with special reference to the Liberation of Hydrogen by the Electrolysis of a mixture of Copper Sulphate and Sulphuric Acid," by Dr. J. S. Sand; and "Electromotive Force and Osmotic Pressure," by Dr. R. A. Lehfeldt.

Institution of Junior Engineers.—At 8 p.m., annual general meeting at Westminster Palace Hotel.

MONDAY, OCT. 29.

North-East Coast Institution of Engineers and Shipbuilders.—At 7 p.m., at Newcastle-on-Tyne, first general meeting of graduates' section. Inaugural address by Mr. H. B. Donaldson on "The Construction of a Modern Merchant Steamship."

THURSDAY, NOV. 1.

Civil and Mechanical Engineers' Society.—At 8 p.m., ordinary meeting. Paper on "Patent Law," by Mr. G. F. Emery.

Rontgen Society.—At 8 p.m., ordinary meeting. Presidential address by Dr. J. B. MacIntyre.

Chemical Society.—At 8 p.m., ordinary meeting.

SATURDAY, NOV. 3.

Institution of Junior Engineers.—At 3 p.m., visit to the Millbank Station of the London Hydraulic Power Company, Millbank-street, Westminster. (Postponed from Oct. 27.)

Glasgow and West of Scotland Technical College Scientific Society.—At 7 30 p.m., at Glasgow. Paper on "Theory, Technique, and Practice," by Mr. T. J. Nicolls.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

MAINTENANCE AND GUARANTEES.

There has been recently a genuine attempt made to remove one cause of friction between consulting engineers and the contractors with whom they have to do. We refer to the model form of general conditions issued by the Cable Makers' Association, in which a limit of time was fixed beyond which cable-makers were not to guarantee their goods. This would seem at first sight to be a faulty policy, as it would prevent the contractor who has great faith in the lasting power of the materials supplied by himself guaranteeing the same in accordance with his personal knowledge. We take it that the real object of the limitation is to prevent onerous guarantee clauses which involve risks impossible to foresee being forced on electrical contractors in general. This is no new phase in the contracting world, and we suppose that a better instance could not be given than that of electric accumulators. In the struggle for orders the manufacturers of these accumulators have been induced in years past to compete the one against the other with respect to their charges for upkeep. It has, of course, been inferred by some that the manufacturer who will for the least annual sum maintain his accumulators must have in consequence the best type. Unfortunately, this has not always been the case, and it will be remembered that one large public company was seriously misled and financially ruined by acting on this supposition. In fact, contractors were induced to offer absurdly low rates for maintenance in order to secure orders with an immediate profit. In the other branch of electrical engineering referred to above—*i.e.*, cable manufacture—the conditions were becoming even worse, as manufacturers were continually asked to guarantee their cables for a long period without any annual remuneration whatever. The beginning of this was distinctly due to one firm of cable-makers offering freely a five-year guarantee. The others, in self-defence, were obliged to follow suit. In our opinion, the majority of the guarantees so given were valueless, and they certainly helped to open up endless opportunities for dispute, which does no good to either the contractors or to the electric light undertakers using the cables. It was only when this rod prepared by cable manufacturers came to be applied rigorously by certain young engineers that some defensive step had to be taken. There is no objection whatever to a manufacturer undertaking to maintain his cables, engines, dynamos, or any other electrical apparatus for a given number of years, provided that he receives remuneration for so doing. He can then ensure the users, not only against faults due to manufacture or erection, but also against the faults which arise from the working of the plant in question. The items for repairs which are found in the accounts of our electric lighting stations would thus be guaranteed at a fixed annual sum, out of which the contractor would expect to make a reasonable profit. We do not say that this course would be advisable, but it shows how unreasonable it is for engineers to expect electrical contractors to include in their original contract sum the annual repair bills which are to be expected for the next

Digitized by Google

five or ten years. These are distinctly not the risks to be included in a contract for the supply of machinery, but rather are in the nature of an insurance by which unduly heavy charges in any one year can be avoided. Another issue of the same question is that the repairs necessarily vary per year, and the engineering knowledge and organising ability of a central-station engineer largely influences the amount required to be spent each year. It is therefore unreasonable to ask the supplier of plant to take in his contract risk the repair items for a period of years, when the engineer who specifies the contract and demands the repairs as required may indirectly cause certain of them. In conclusion, it is the engineer's duty to run and maintain the works and mains after they are taken over from the contractor—and the time at which they are taken over should not be unnecessarily long—and we are glad to see that certain manufacturers are refusing to take up this duty. The engineer should in no way try to shirk his responsibility.

CORRESPONDENCE.

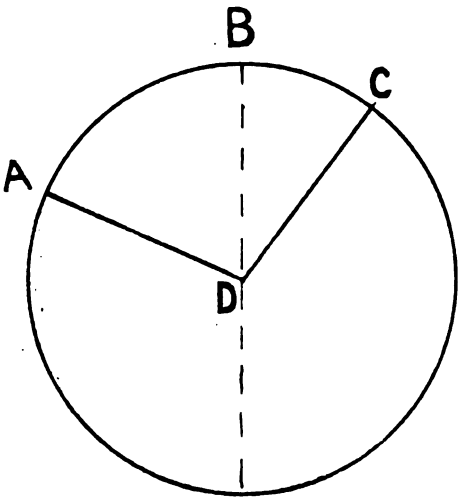
"One man's word is no man's word,
Justice needs that both be heard."

ELECTROMAGNETIC INDUCTION.

SIR,—As this letter offers experimental proofs of my contention which Mr. Johnston and others have disputed, you will probably agree to print it, although the discussion has certainly lasted too long. I have nothing more to say concerning Dr. S. P. Thompson or other authorities, except that Mr. Johnston is altogether unjustified in saying that the passage I have quoted from "Dynamo-Electric Machinery" referred solely to the case of "a closed coil moving entirely in a uniform magnetic field." Dr. Thompson neither says nor implies that this is so.

The experimental proofs I am about to offer are so obvious that it is a wonder they have not long ago occurred to myself, to Mr. Johnston, or to the editor of *Lightning*, the latter of whom severely criticises me in his journal, and refuses to let me reply. They are as follows: (1) send a current through the primary of a transformer, and you get a current in the secondary; (2) suddenly stop a current in any circuit, and you get a momentary induced current. Both these results are readily explained on the theory that ascribes induction to a variation in the magnetic field embraced by the circuit; but they are inexplicable on the popular theory which ascribes induction to a cutting of magnetic lines by the conductor. In the case of the transformer, how can there be any cutting between magnetic lines *inside* the core and conductors *outside*? And in the other case, can it reasonably be asserted that the magnetic lines set up by the original current rush across the conductor when the current is stopped, cutting it on their way and thus inducing another current? It may be well to mention that the lines of *leakage* in a transformer are prejudicial to its efficiency, so that the lines which cause the current must be those inside the core, which could not possibly be cut by the conductors that are outside.

If I may trouble you to reproduce this diagram, I shall be able to answer Mr. Johnston's challenge to explain the action of a unipolar dynamo on the *variation* theory. Let the circle be the rim of a wheel armature in a unipolar dynamo, and let A D, D C be any two spokes on opposite sides of the line B D, B and D being the points at which the sliding contacts are made. When the wheel revolves clockwise, assuming that the magnetic lines are flowing through the wheel towards the observer, the motion of D C evidently causes an increase in the number of lines in the space B D C, giving rise to a current from C to D (clockwise); and the motion of A D evidently causes a *decrease* in the number of lines in the space B A D, giving rise to current from A to D (counter clockwise). The action of the dynamo is thus perfectly explained on the theory I defend. The editor of *Lightning*, who questioned the possibility of explaining such a dynamo on this theory, declines to print the explanation just given, but tells his



readers that I have sent him a "quite erroneous explanation." This is scarcely the treatment one would expect from a scientific and fair-minded man.—Yours, etc.,

W. F. DUNTON.

THE PATH OF THE SUN.

SIR,—From a letter in your issue of the 19th inst., I conclude that Mr. Sandeman considers that I have criticised him unjustly, and attempted to discount the value of his theory as to the path of the sun on the strength of my individual opinion. Since this is by no means the case, may I claim your indulgence for a few lines?

Mr. Sandeman complains of my treating as a fallacy his statement that the revolution of the nodes of the sun produce a conical motion of the earth's axis amounting to 47deg. I did not treat his statement to this effect as a fallacy, since "it is impossible to reply to an oracular assertion." When Mr. Sandeman states that he believes "the sun to revolve round the earth in 25,800 years, that he holds the earth in a firm grasp as a consequence of the gravitational action on the protuberance, and as he progresses round the earth, takes it round with him" ("Path of the Sun," p. 85), though one may dispute his contention that "there is no evidence to show the opinion to be erroneous," we must at least admit his right to hold this or any other view if he so chooses. What I stigmatised, and still stigmatise, as a fallacy is his argument that since the revolution of the nodes of the moon produce a small motion of the earth's axis about the position it would occupy if undisturbed, *therefore* the revolution of the nodes of the sun will produce a conical motion of the earth's axis, amounting to 47deg., about an axis perpendicular to the ecliptic.

I must admit myself to be completely at a loss to understand Mr. Sandeman's contention that "a calculation cannot prove the nature of a movement," and that "to prove anything relating to a quality, condition, or attribute by figures is impossible." Any quality, condition, or attribute of a body which can be measured, and thus known quantitatively, can be made the subject of calculation. The motion of the polar axis of the earth is a case in point. I must regretfully decline the "palm of superiority" which Mr. Sandeman offers me, since a complete calculation of the precessional motion of the earth's axis has already been effected. This may be found in full in "Rigid Dynamics," by E. J. Roath, M.A., F.R.S., etc. (Macmillan and Co.).—Yours, etc.,

EDWIN EDSER.

Putney, Oct. 22, 1900.

GOSFORTH.—The Board of Trade have confirmed the Gosforth and Ponteland light railway order.

GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE SCIENTIFIC SOCIETY.

The opening meeting of the eighth session was held in the large hall of the college last Saturday, when Mr. Henry A. Mavor, M.I.C.E, M.I.E.E, past-president, occupied the chair.

Mr. DAVID HOME MORTON, M.I.C.E., M.I.M.E., delivered his presidential address on "The Standardisation of Machinery." Nature, the president said, did not standardise, inasmuch as no two creatures were exactly alike, nor in her infinite wisdom did Nature make each individual symmetrically perfect, no matter how perfect the female form might appear. In some cases man, however, found it an ever-present necessity to do what Nature declined to do, and he had reached a degree of perfection which, while in no way indicative of finality, was a striking testimonial to his mechanical genius. The object of all industrial production was gain to the producer, and the greater the margin between the prime cost and selling price the greater the gain, hence the necessity of introducing every means which could be devised in order to reduce the cost to the producer. Our American and Continental friends had in this, as in some other respects, beaten us, but for many years past our most progressive British firms had recognised the value of standardisation and acted accordingly, while even our most backward firms were now recognising the necessity of setting their house in order if they were to have any place at all in the industrial world. Complete standardisation was not possible, owing to the repairs and renewals for existing machinery, and owing to the man who, usually spending other people's money, must have something different from anything which had been made before. The man who would cultivate standards must be strong, and it would be well for him to be philosophical, for in his declining years he might see the silly gander and the donkey wandering aimlessly over his well-ordered garden. When he was no longer able to take an active interest in the management of a business, his successor might, with a view to asserting his own individuality, but more often displaying inferior mechanical skill and organising ability, depart from the established order, and set up other standards on perhaps an ill-considered basis. The man who saw his work thus ruthlessly swept away after it had probably passed through the evolutionary process associated with such work, must console himself with the reflection that, after all, the loss was not his, and that time only would prove the merit of any standards, old or new. The adoption of systems of standardisation, if success was to be won, must be accompanied by the common-sense working of the systems. Passing to details, the Whitworth standard, from which the Sellar's or United States standard for screw threads differed but little, was a step in the right direction. But even that was not ideal, giving as it did in the larger sizes a thread too coarse for the highest class work, thus pointing to the need of reconstructing the standard. There was nothing to prevent flanged connection being standardised, both time and money being saved, by the use of standard drilling templates, particularly for the smaller and more common sizes. Valves and valve-chests were full of lessons in standardisation, while plummer blocks, or chairs or pedestals lent themselves not only to standardisations of dimensions, but also to nomenclature. Many firms made a speciality of shafting and gearing, and from them it was recommended that the buyer should purchase his requirements. So, too, with many of the details. Standardisation of complete machines was simply a fuller development and the logical sequence of the standardisation of detail. Many works in the United States, and not a few in this country, had done well in producing engines, machinery, etc., in standard series, as instance Willans, Belliss, Tangyes, Robey, Babcock and Wilcox, and many others. All these firms, not content with the result of past efforts, had spent and were spending freely of their gains in order to produce results still more satisfactory, and to make their position in the commercial world as nearly impregnable as it is possible to be.

At the conclusion of Mr. Morton's address, a few remarks on the subject were made by several gentlemen present. A Japanese member of the society, in a speech made in excellent English, pointed out the difficulty which younger nations experienced from the want of international standards. He thought that a standard system of weights and measures ought to be one of the first objects of civilised countries. The metric system, he thought, was especially suited for international trade, and he hoped that some effort would be made to secure a reliable basis common to all trading countries. Britain, in the East, laboured under a serious disadvantage in this respect.

The CHAIRMAN said that not only were the machines as made in his own works standardised, but by the introduction of definite methods of shop organisation a surprising saving in the working expenses had been obtained, with an equally great improvement in the accuracy with which shop records could be kept.

At the conclusion of the proceedings Mr. Morton was awarded a hearty vote of thanks for his interesting and valuable contribution to the literature of a difficult and important subject.

THE E. L. B SYSTEM OF LIGHTING.

On Friday last the Electric Lighting Boards and Strips Company invited the Press to a private view of their system of lighting. The electrical boards in question consist of a number of copper conductors stretched in a network over a certain area, and insulated from each other by hardened asbestos. On top of the conductors is placed indiarubber, asbestos, and cork, the latter forming the surface of the board. The lamps used have a specially-prepared collar, which has two phosphor-bronze spikes as the terminals of the filament. These spikes are pressed through the layers of cork, indiarubber, etc., until they reach the conductors underneath. The spikes are set such a distance apart as that wherever they are pressed into the board two opposite poles are found. The asbestos insulation between the conductors is very thin, but is hardened so that a spike cannot enter it and thus cause a short-circuit. The conductors themselves, in order that the spikes make good contact, are formed of small bundles of wires in the same fashion as flexible wires are constructed. The system can be applied to very narrow strips for running along a room or elsewhere, and can be made as a kind of cable for decoration purposes. In order to prevent the lamps from being shaken out on wall or ceiling strips which are subjected to much vibration, the lamps are supplied with a detachable clip, which is twisted round and grips under the edges of a beading, which is run along the top and bottom of the strip. It is claimed by the company that by this system of wiring the ordinary method now used of wiring each individual point will be to a great extent superseded. There is no doubt that in some instances such a system would be of great use, but we do not think that in certain of the applications for which the company think it very suitable it will oust the present method of electric lighting by means of lamps on flexible cords. The method is claimed to be in the long run considerably cheaper than the ordinary wiring system, but it remains to be seen how a board will work after a year or two's wear. There is, we should think, a possibility of the cork surface crumbling out, and a general renewal being found necessary. For theatre signs it is claimed, and with good reason, that this system is much more convenient than the old. This would be so more particularly in the case of a provincial theatre, where a different piece is acted every week. In this case the lights could be easily shifted from forming the name of one play to form that of another. For temporary work, such as decorations on special occasions, the system should also be found very convenient. The system is also specially recommended for showcase work, and for those willing to go to the expense of fitting it would no doubt be found very convenient. Lamps connected with flexible wires could, however, in most cases give an effect which is quite as good. Another point in connection with the pushing in and pulling out the lamps is that there is great danger of

Digitized by Google

persons who do not understand the matter catching hold of the bulb of the lamp and pulling, in which case it would probably come away from the socket. There is, however, one would think, a successful future before the system, which in certain cases would undoubtedly prove more convenient than the ordinary system of wiring. The Electric Lighting Boards Company gave illustrations at their factory in Dean-street, Soho, of the various uses to which their system can be put. The offices of the company are, however, at 7, Pall-mall, S.W.

THE ELECTRICAL ENGINEERS (R.E.) VOLUNTEERS.

At the present time, when volunteers have proved to the general public that that portion of the auxiliary forces is no mere pastime for a number of men, but a very real item in the defence of Great Britain, it is interesting to electrical engineers to note that recruiting for their own special corps, the Electrical Engineers (R.E.) Volunteers, commences next Thursday, Nov. 1. The men are examined and enlisted at the headquarters of the corps on Tuesdays and Thursdays, commencing with the above date. The members of the corps have done really good and useful work out in South Africa, and their example should cause a large number of members of the electrical profession who have not joined to do so at once. As may be remembered, the object of the corps is to bring together a body of men having adequate knowledge of applied electrical science, and to train them in the application of their knowledge to the defence of their country. The principal duty will probably be to supply officers and men to assist their comrades in the regular Royal Engineers in working defence electric lights at the defended ports, but their special technical knowledge will also be used in many other ways. The conditions of service are much the same as for the Volunteer Royal Engineers, and to qualify for efficiency a man must attend a considerable number of drills and have passed a certain electrical course. In the Submarine Miners' corps, to which the conditions in Electrical Engineers' corps are very similar, a man must attend 78 submarine mining drills and have had eight days' continuous training. He must for the first year's service have passed the requisite examination. For men with over three years' service a less number of drills are required. The uniforms of the rank and file are found by the corps, but the officers have to purchase theirs. Towards this expense, however, we believe a grant is made by the War Office which almost covers the cost. When in camp the corps would receive the ordinary pay of the regular Royal Engineers, together with special working pay when engaged in following their professional work as volunteers. We would strongly recommend, now that the corps is open to take recruits, that any members of the profession who can do so should join, and the working drills and instruction given would probably prove very useful in their private occupations as well as to the corps itself. The officer commanding during the absence of Major R. E. B. Crompton is Major R. Erskine. Any information which may be required by intending recruits can be obtained by writing to the officer commanding at headquarters, 13, Victoria-street, S.W., who will be pleased to send all particulars.

THE FACTORS WHICH DETERMINE THE DESIGN OF MONOPHASE AND POLYPHASE GENERATORS.*

BY B. A. BEHREND.

The path of the designer of alternating-current machinery has been beset with extraordinary difficulties. At a time when direct-current machines could be designed with an accuracy equalling that with which the dimensions of steam-engines can be predetermined, the designer of the alternator was still groping in the dark. The invention of the asynchronous single and polyphase motor, though stimulating and enhancing the interest attached to the solution of the problem, only increased, at first, the difficulties. It was found that alternators, which gave satisfactory results when working on non-inductive loads, were utterly worthless for induction motors. To the surprise of many a designer, the drop of voltage was so immense that by no increase of the exciting current could the voltage at the terminals be raised to its proper value.

An explanation of this phenomenon was afterwards easily given, and our periodicals were rife with mathematical theories to account for the observed phenomena. I am far from thinking that such speculations are without value—they very often hasten the approach of the final solution of a controverted question—but, as they usually abound with *a priori* assumptions which are by no means justified by experiment, they are like a double-edged sword in the hands of the designer. Long deductive arguments not based on the solid ground of experiment are premature, and the energy wasted on them would far more wisely be spent in widening our knowledge of experimental facts.

There was another factor which contributed to obscure the real points at issue—viz., the frequency of the alternating current. The frequency of alternating currents has not sufficiently been dealt with from the standpoint of the designer of the alternator or motor, but only from the standpoint of the light-installing engineer. He held that the frequency, or number of complete periods per second, ought to be, for his transformers and lights, at least over 50, and frequencies of about 80 did not belong to the exceptions, but were rather the rule. Now, such high frequencies may be justified as long as the alternating current is dissipated altogether in heat or light, in which case the greater inductive drop accompanying the higher frequency, being in quadrature with the current, is not fatal. As soon, however, as inductive currents were taken from these machines with high frequency, the voltage at the terminals dropped beyond control, betraying the unsatisfactory design of the generators.

In America the designers resorted to an expedient, curing, so to say, the symptom, but not doing away with the real evil—viz., they compounded their generators—while in Switzerland and also in Germany, the only countries in Europe that took part in the development of polyphase work, other ways were chosen. We can hardly think of a country more favourable to the development and spread of so flexible a system as the polyphase current system than Switzerland. A rich country, abundant in water power, covered with villages and fine hotels, full of small industries, needing light and power over comparatively large areas, Switzerland has proved a hotbed for the growth of the polyphase currents; and it was in the Oerlikon Engineering Works in Switzerland that the author had the opportunity of investigating the principal factors which determine the design of alternating-current machinery. The following article contains some of the results at which I have arrived.

I propose to deal with the problem in the following manner: We shall first mention the factors which are necessary to predetermine the static characteristic of the alternator. We shall then turn to the methods by which the dynamic characteristic can be determined, and shall discuss them in the light of a series of experiments. The last chapter will be devoted to the influence of the frequency, of the pole-pitch, and of the air-gap on the drop. The results there attained will furnish us a simple and very useful method of designing alternating-current machines.

I.—The Static Characteristic of the Alternator.

This section may be briefly treated, as Mr. Gisbert Kapp's excellent works on the subject give all information desirable. Some points here touched upon are inserted only for the sake of completeness. The following formula gives the value of the effective E.M.F., e, which is induced in the armature possessing z active conductors:

$$100\, e = k \sim z\, F\, 10^{-6} \text{ volts} \quad . \quad . \quad (1)$$

In this formula $\sim$ stands for the frequency—that is, the number of complete periods in one second; z, as said above, is the number of conductors or wires that are cut by the lines of induction; F is the number of lines of

* From *Electrical World and Engineer* (New York).

Digitized by Google

induction emanating from each pole, in C.G.S. units; k is Mr. Kapp's coefficient, dependent upon the ratios of the width of the coil and the width of the pole to the pitch of the poles. The following table contains the value of k for different arrangements, after Kapp:

Width of coil / Pitch of pole		0	1/3	1/2	2/3	1
Width of pole / Pitch of pole	1/1	2	1·76	1 64	1 69	1·16
	2/3	2·40	2 31	2 13	1·94	1·49
	1/2	2·83	2 50	2 32	2·12	1·64
	1/3	3 46				

If the leakage at the edges of the poles—the fringe of the magnetic field—is properly taken into account, the values of k in the table give very good results for machines with revolving poles of alternately varying sign, as well as for inductor generators. There is very little difference in the determination of the static characteristic of machines with revolving poles in which each pole is excited by a single coil, and of ordinary direct-current machines; hence the great mass of experience that direct-current engineers have accumulated, can at once be utilised by the designer of this type of alternating-current machines. The so-called

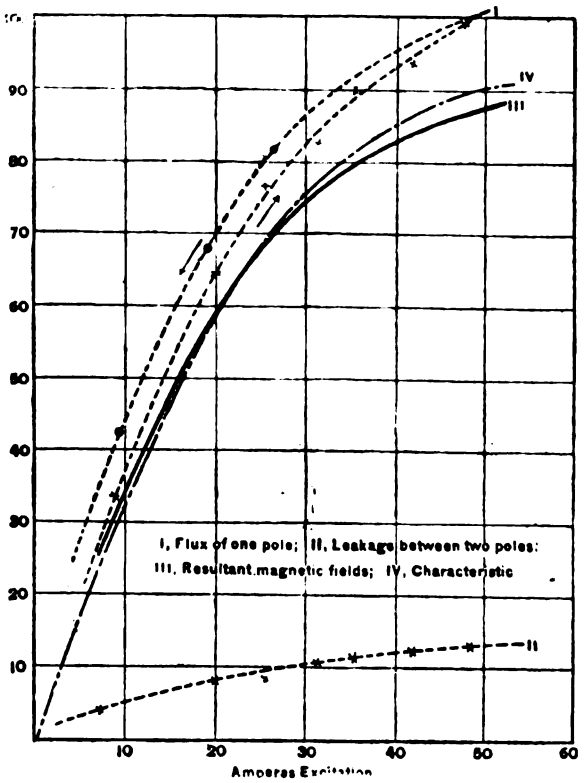

FIG. 1.—Leakage Test Curves.

Lauffen type has practically disappeared from the market because of its immense leakage and other drawbacks connected with the revolving circular coil. I need, therefore, not dwell upon the bitter experiences with this machine. I should like, however, to make some remarks about the inductor generator, which still enjoys a better reputation than it deserves.

From the standpoint of the electrician these machines are inferior to those with alternating poles on account of the leakage between two adjoining pole-horns, which conditions I shall immediately illustrate by some curves. From the standpoint of the mechanical engineer the high induction in the air-gap—which must be kept small on account of the leakage—causes even with very slight eccentricity of the revolving part such immense one-sided magnetic stress that the shaft has to be made far heavier than in the revolving-pole type, and difficulties with the bearings, if not very amply proportioned, are by no means exceptional.

I measured in 1897 the leakage in an 800-kilo-volt-ampere generator designed by Mr. Emil Kolben a year before in the Oerlikon Engineering Works. The method employed was one that Mr. Kapp had used a long time before for determining the leakage in direct-current machines. The method is based on the same principle as the instrument of the late Dr. John Hopkinson for determining the magnetic properties of iron. A coil was formed of some turns of a very thin wire which was affixed to a sheet of cardboard. The coil had the same dimensions as the armature coils, the pitch of the coil being equal to the pole-pitch. The ends of this exploring coil were connected to a ballistic galvanometer; in our case a sensitive Weston instrument was sufficient.

The air-gap of the generator was 0·5cm., the pole-pitch 23·5cm, the width of the pole 23·5cm., equal to the pole-pitch. While the inductor of the generator was standing still, the field was excited, the exploring coil was placed between a pole-horn and the armature, and then pulled out. The deflection of the galvanometer is thus proportional to the total number of lines of induction entering the armature from one pole-horn of the inductor. The coil was then placed between two adjoining pole-horns and again pulled out. The deflection measures the leakage field, which acts in an opposite direction to the main field.

The curves in Fig 1 show the result of these tests. The abscissæ of the curves represent the exciting current, the ordinates the deflection of the galvanometer. The two curves, measured as described above, are represented in broken lines, while the resultant magnetic field is represented by the full-line curve. The curve plotted thus —.—.—.—.—. is the static characteristic of the generator. The almost perfect agreement between this curve and the curve of the resultant magnetism is interesting to notice. If the resultant magnetism is set equal to 100, then the leakage field has the following values for different excitations:

Exciting current.....	10	20	30	40	50	amperes.
Leakage field	14·3	13·8	13·4	14·6	15·3	,,
Resultant field.....	100	100	100	100	100	,,

The leakage between adjoining poles is, therefore, about 15 per cent. of the resultant magnetism. In other words, the leakage field induces a counter E.M.F. in the armature coils equal to 15 per cent. of the resultant magnetism; besides, the cross-sections of the iron parts have to be proportioned for all these leakage lines. Hence, this leakage of 15 per cent. is equal to a leakage of 30 per cent. in a generator with alternately-wound magnets. It may be remarked that the leakage thus measured does not include all the leakage lines, as some are entering the frame holding the two armatures without passing through the armature coils. But this leakage field is not considerable, and may generally be neglected.

The leakage coefficient varies, of course, between certain limits in machines of the same type, but of different size. The factor is partly dependent upon the ratio of the air-gap to the width of the poles, partly dependent upon the absolute value of the pitch of the poles. I have never found the leakage factor under 20 per cent., this being the lowest value found in machines with an air-gap of $\frac{1}{16}$in. and a pole-pitch of 9in., while in generators with a pole-pitch of 5in. and an air-gap of $\frac{1}{8}$in. for slow speed, the leakage factor rose to the immense value of 45 per cent.

That the absolute value of the pole-pitch is of such paramount importance is quite clear if we bear in mind the fact that the magnetic resistance of the air-gap in direct-current dynamos with slotted armatures is hardly increased by the open slots. We cannot emphasise this point strongly enough, as a small pole-pitch has been the cause of the failure of many a generator, and as these machines chanced to be for high frequencies in the majority of cases, the failure was attributed to the high frequency, though, in fact, due to a too small pole-pitch. We shall return to this point in the section of this article discussing the short-circuit characteristic.

Fig. 2 will demonstrate the influence of a small pole-pitch on the static characteristic of the generator. Curve I. represents the characteristic of an inductor generator, running at a speed of 500 revolutions per minute and developing a three-phase current of 50 periods per second. The number of pole-horns is six on each side of the exciting coil. The pole-pitch is equal to the width of the poles—viz, 27·6cm. Curve II. represents the characteristic of a generator of the same type and size, running, however, at

Digitized by Google

a speed of 250 revolutions per minute, and being wound for 50 periods per second. The inductor has, therefore, 12 pole-horns on each side of the exciting coil, and the pole-pitch is 13·8 cm. The two characteristics ought to be alike, if the leakage in both machines were the same. The tremendous difference between the two curves is due entirely to the great leakage caused by the poles being too close together.

What has been said of the influence of the pole-pitch on the leakage in inductor generators holds good, with some qualifications, also of generators with alternating poles, though the increase of the stray field is not so immense as in the case of inductor generators, because the leakage lines do not induce a counter E.M.F. in the armature. While the leakage factor in the generator, the characteristic of which is represented by Curve II., proved to be about 45 per cent., the leakage coefficient for a generator with alternating poles and a pole-pitch of 14·1cm. was 30 per cent. for the same ampere-turns in the field. The air-gap of this generator was 0·35cm., while the air-gap in the inductor generator was only 0·3cm. These figures show clearly the superiority of the alternating-pole generator over the inductor generator.

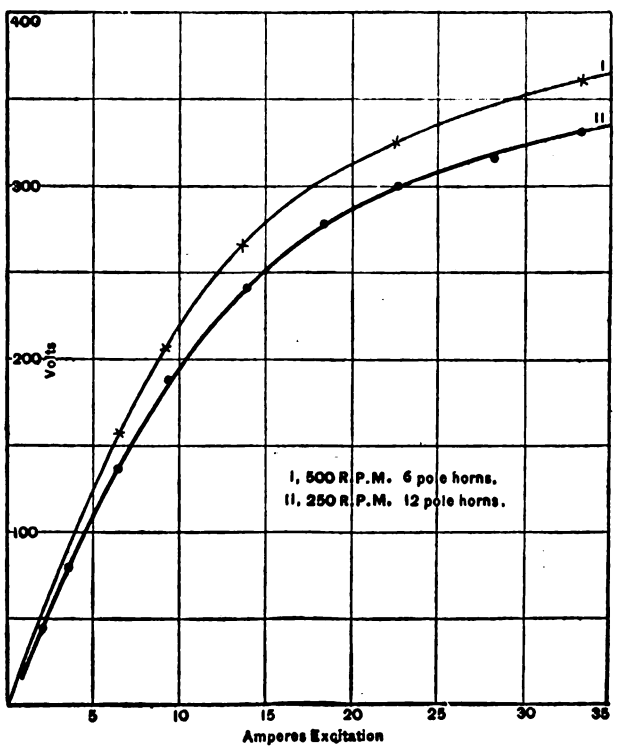

FIG. 2.—Curves showing Influence of Pole Pitch.

Thus, all our experiments in regard to the static characteristic impress upon us the paramount importance of a great pole-pitch, if we desire to keep the leakage within reasonable bounds.

II.—THE DYNAMIC CHARACTERISTIC OF THE ALTERNATOR.

That the determination of the dynamic characteristic of alternators is bound up with far greater difficulties than are met with in the determination of the static characteristic, need not be told to the designer of alternating-current machinery. Indeed, it is not very long ago that the obstacles in the way of the designer seemed almost insurmountable. To-day it must seem almost ludicrous to those who have taken active part in the evolution of alternating-current machinery, and who have eventually arrived at clear ideas, that the form of the wave of the E.M.F. was invariably made the scapegoat for mistakes in the design.

A great step toward the solution of these problems was taken when the short-circuit characteristic of the alternator was made use of, if I mistake not, first in 1895 by Dr. Behn-Eschenburg. From the theoretical standpoint his method could hardly be considered satisfactory; a great many objections might be justly urged against his theory. But as a method for determining the drop it has proved very valuable. Dr. Behn-Eschenburg had arrived at his result by treating the alternator like a transformer, in which case the method is correct. Everybody is to-day familiar with Mr. Kapp's admirable way of determining the drop of voltage in transformers. The simplicity of his method, the ease with which it explains phenomena so complex as the so-called "Ferranti effect," would make it most valuable to the designer of alternators, if it were applicable to these machines. The present author has contended for the past three years that we are justified in applying this method, in spite of its theoretical inaccuracy, to the calculation of alternators if we are only mindful of the assumptions on which the method is based. The following series of experiments will justify this position.

It is well known that the maximum drop occurs in alternating-current apparatus when the current lags behind the E.M.F. by one-quarter of a phase. Furthermore, it can easily be shown that for a power factor below 0·60 the drop is practically equal to the drop caused by a wattless current. In our investigation we shall therefore study the influence of wattless currents on the drop. A large drop is, of course, the most favourable for the verification of the theory. A small drop, as caused by currents in phase, or nearly in phase, with the E.M.F., is not suited for rendering a decision as to whether a theory which lays claim to the determination of the drop is correct or not. The use of wattless currents for the determination of the drop has the further advantage that the drop caused by the ohmic resistance of the armature may be neglected without any inaccuracy worth mentioning.

(To be continued.)

LIGHT RAILWAYS.

The Commissioners have held an enquiry into light railway schemes, one of which was promoted by the British Electric Traction Company for an extension of their order, authorised in the last session of Parliament—for the construction of light railways in the borough of Barnsley and in the townships of Monk Bretton and Worsborough—to establish a line from the terminus of that in the present order at New England, Worsborough Bridge, to follow the main road from Barnsley to Hoyland Common, passing through Worsborough Bridge and Birdwell, then turn to the left to Hoyland Nether, and to end in front of the town hall. The Great Central Railway Company opposed. The Commissioners stated they were willing to grant the order for the light railway, including the level crossing, but they thought a clause should be put in to the effect that any extra expense which the Board of Trade might put the Great Central Railway Company to in consequence of the light railway crossing their line should be thrown upon the promoters, at least to such extent as the Board of Trade thought reasonable.

The Commissioners have held an enquiry into the application of the Kidderminster and Stourport Electric Tramway Company for powers to construct a line from Kidderminster to Bewdley, with a branch to Franche. On Saturday the Kidderminster and Bewdley Corporation authorities received intimation from the secretary to the Commissioners that they would recommend the Board of Trade to sanction the construction of the line for the whole of the route for which the promoters asked powers.

At the last meeting of the Gloucestershire County Council it was resolved to contribute £15,000 towards the Witney, Burford, and Andoversford Light Railway.

The success which has already attended the Goole and Marshland Light Railway has led to an important extension scheme, which has now been completed. The Board of Trade sanctioned a branch railway from the main line from Goole to Luddington and Adlinfleet, leaving the main line at Eastoft. This has now been abandoned, and in substitution the directors have completed arrangements, by friendly agreements with the landowners, to extend the line from Luddington to Garthorpe, a populous township in both the West Riding and Lincolnshire, and not a great way from the River Trent.

The Commission held an enquiry at Swansea on Oct. 24 into the application for permission to construct the Swansea and District Light Railway, and they will resume to-day at the Royal Hotel, Cardiff, the public enquiry into the application in respect of the Rhondda Valleys Light Railway.

Mr. Nevins, the promoter of the light railway from and through Cheltenham to Cleeve Hill, has submitted to the Tramways Committee of the Corporation designs of the cars and rails proposed to be used on the line. It is hoped that the work of constructing the railroad will be commenced within the next two months. No arrangement has yet been come to with the Corporation for the supply of the electrical energy,

Digitized by Google

but the completion of the line is not likely to be delayed on this score, and the terms of supply will be readily settled under the arbitration clause should it be necessary to put it in force.

The Commissioners held an enquiry on the 25th inst. into the scheme for providing Llanelly with electric light and traction.

At a meeting of the General Purposes Committee of the Darlington Town Council on the 21st inst. objections to the recent order of the Light Railway Commissioners were considered. The order, which deviated very considerably from the conditions originally proposed, has caused a good deal of dissatisfaction amongst the members of the Council, and it was arranged that a number of objections should be formulated thereto.

THE ELECTRICAL TRANSMISSION COMPANY'S SWITCH GEARS.

We have received from the Electrical Transmission Company, Limited, of Albert Works, Hammersmith, a well-executed catalogue and price-list of their several specialities. An introductory attached explains that whilst the firm's special patent devices entitle their apparatus to consideration as being the most advantageous, electrically, offered on the market, their purpose is to only supply switch gear of a substantial character, made with the best materials and workmanship, and provided with an ample margin for contingencies of overload, etc. Amongst other patent devices of recent introduction dealt with in this catalogue may be mentioned the automatic motor-starting switches, constructed under the patents of Mr. Walter F. Jones, A.M.I.E.E., M.I.Min.E., engineer and manager to the company, which, it will be remembered, were fully described and illustrated in our issue of Sept. 14 last. As to the claim of substantiality put forward on behalf of the apparatus offered, the justification may best be judged from the accompanying illustrations taken from the catalogue. Figs. 1, 2, and 3 illustrate respectively single, double, and triple pole switches with fuses of the firm's "K" type. A price-list of these switches for voltages up to 250 is given. In the 500-volt switches the breaking distance is increased, and in the double-pole type for this voltage the two iron levers are connected by a black fibre bar, and not screwed to the handle as shown. Fig. 4 herewith illustrates a traction panel of the firm's standard make, equipped with "T" type switches. The special features claimed for these switches are as follows: They lie close to the panel both in the "on" and "off" position, so permitting

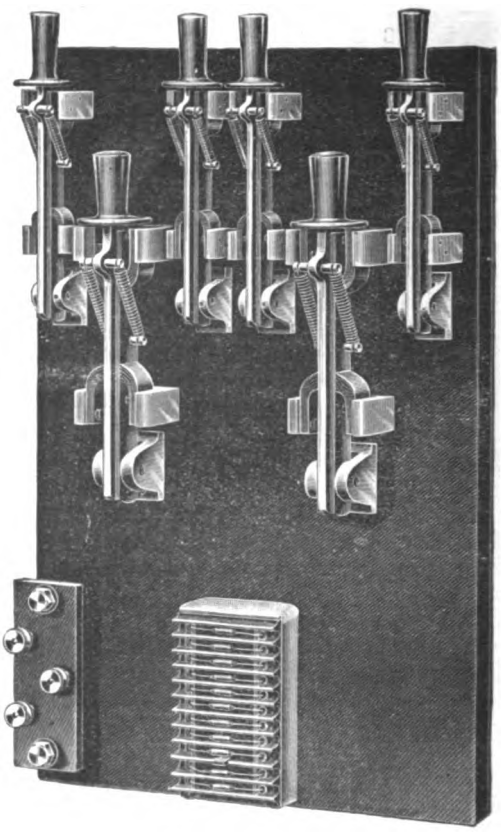

FIG. 4.—Traction Panel.

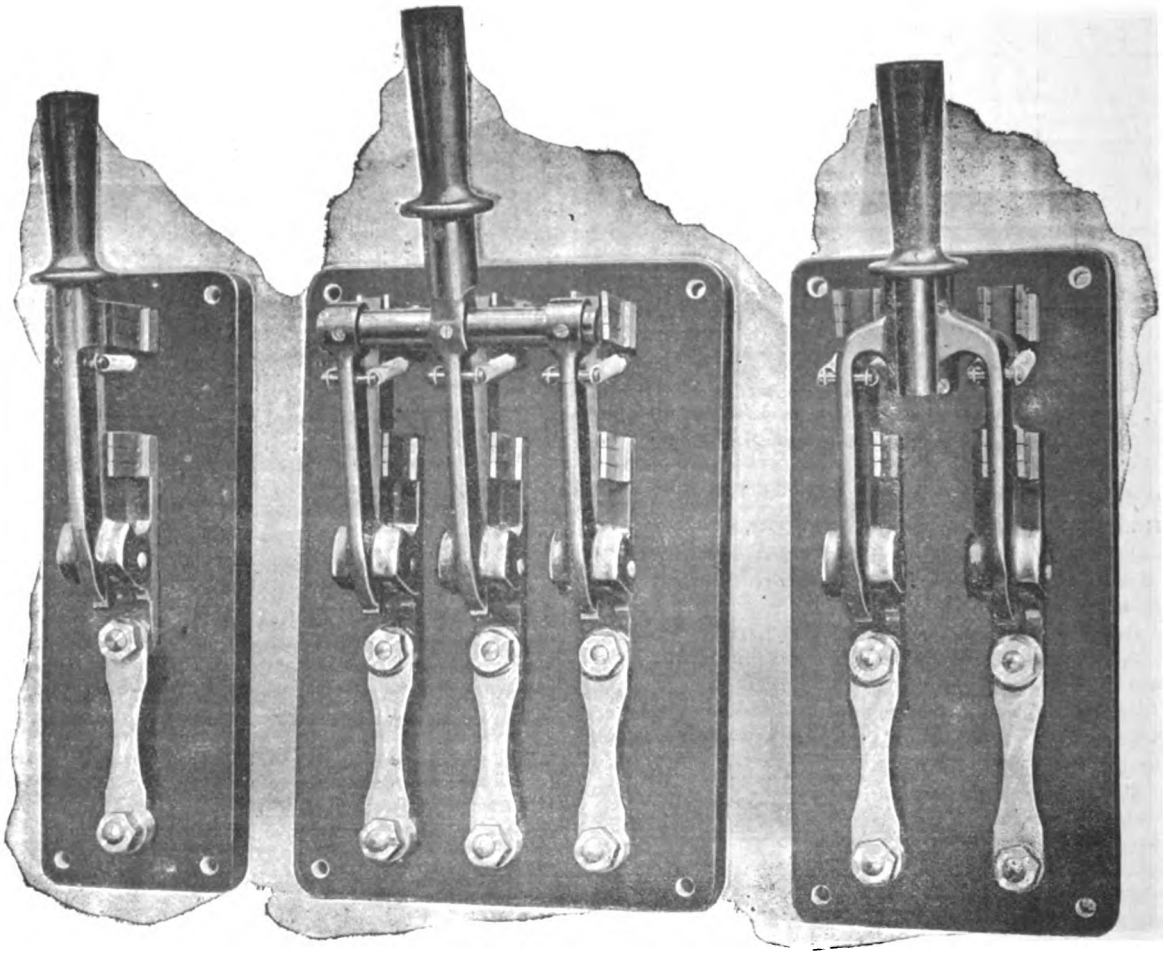

FIGS. 1, 2, AND 3.—Single, Double, and Triple Pole Switches with Fuses.

Digitized by Google

a small depth in the street section pillars; they have an excellent "quick-break' action, and are suitable for 500 to 700 volts; they are fitted with laminated copper contacts. These switches are also supplied mounted in cast-iron cases, with or without fuses, for cutting off the current from motors. Other types of switchboards and switches are described and illustrated, also arc lamps of the firm's manufacture, of which latter we understand a large stock is kept ready for immediate delivery.

ELECTRICAL HEATING FOR BUILDINGS.

The Prometheus Company, of Bockenheim, have for some time manufactured cooking apparatus and heaters of various descriptions which have met with great success both in this country and on the Continent, and their sole agents here, Messrs. O. Berend and Co., Limited, of Basinghall-avenue, London, E.C., are continually introducing new patterns of cooking apparatus and new applications of the patents owned by the Prometheus Company. Under this company's patents the electrical energy is converted to heat through resistances formed of thin films of precious metals, such as gold, platinum, etc., deposited on an insulating base of mica, enamel, or other suitable material; resistances up to 25,000 ohms can thereby easily be obtained. It is evident that the scope for the use of resistances of this description is practically unlimited where a heating effect is required, and these deposited on a mica base have lately been adopted for electric heating stoves or radiators. Although the use of electric energy for this class of heating has generally been considered too expensive, cases frequently arise where the advantages it affords far outweigh the question of cost; and where the cost of coal is high and electric energy can

FIG. 1.

be obtained cheaply, radiators of this description can be used to advantage. There is also a large class of users of electric energy to whom the question of cost is of no importance if greater comfort and convenience can be obtained; thus a mansion at Frankfort has now been fitted with these radiators throughout, and all other means of heating and warming abandoned. In hotels and other large buildings fitted with steam or hot-water circulating systems, it is often necessary to heat one or more rooms at a time when, as in spring or autumn, the main heating system is not at work. To start the whole system merely for the purpose of warming one or two rooms would be excessively inconvenient and expensive. There is in this direction a large scope for electric radiators, as the convenience of this class of heating for rooms not continually occupied, such as bedrooms, bathrooms, etc., scarcely calls for comment.

With the exception of the Dowsing luminous radiator, those now in use are cumbrous and heavy, having a large amount of metal, etc., in connection with the resistances, which absorbs a considerable amount of energy and time before they either radiate or emit heat; electric stoves or radiators should be designed to act as quickly as possible—in other words, the amount of metal and other heat-absorbing material in connection with the resistances should be reduced to a minimum. This is impracticable in the case of stoves or radiators in which the resistances are formed of wires embedded in enamel. This type requires a large mass or weight of inert material, which has to be heated before any external duty is obtained from the stove, and they are consequently very slow in producing any sensible increase in temperature. In the stoves designed by the Prometheus Company this point has received great attention, and it may be of interest to describe some of the factors on which the design has been based. A mica strip, $5\frac{5}{16}$in. long by $1\frac{3}{16}$in. broad and $\frac{4}{1000}$in. thick, coated, under the Prometheus patents, with a film of precious metal, had a resistance of 120 ohms, and at 110 volts absorbed 0 81 ampere, or 89 watts. The mass or volume of the mica is, of course, extremely small, and the resistance radiates practically 76 calories per hour immediately. An average room of 3,530 cubic feet capacity requires some 2,000 to 2,500 calories per hour to warm it, and 30 of these resistances would therefore be required. The weight of the mica strip is practically nil, and the terminals or connections can be kept very light. The combination, therefore, absorbs but little heat, and practically the whole of the energy is at once available. Compare this with similar resistances embedded in enamel and carried in metal frames and supports, and it will be seen that these strips possess great advantages as transformers of electric energy into heat energy. In practice, to ensure durability it is desirable that the temperature of the

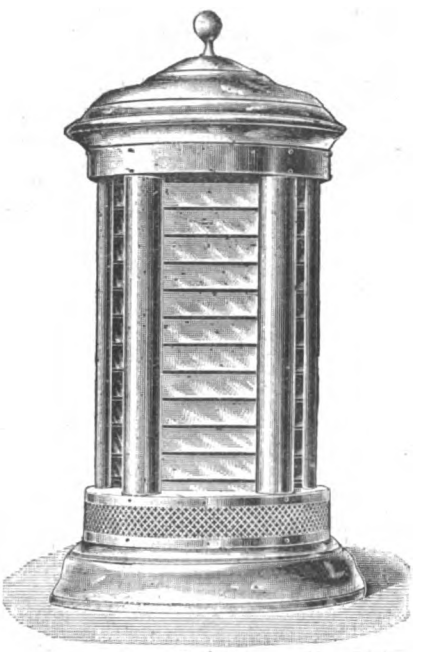

FIG. 2.

strips should not exceed 450deg. This corresponds to 70 or 75 watts per strip. At 90 to 100 watts the strips show dull red in the dark, and oxidation would then occur. As stated above, resistances up to about 24,000 ohms can be obtained on a strip measuring $5\frac{5}{16}$in. $\times 1\frac{3}{16}$in. $\times \frac{4}{1000}$in., and they can be connected in parallel in any number required to obtain the desired effect of the stove, and can be designed for any pressure of supply and for any temperature of the stove up to 400deg. C.

The stoves designed by the Prometheus Company for these strips are circular, thus affording the greatest strength for the least weight, the number of strips employed depending on the size of the stove. These strips are mounted in two rows on a frame fitting into the circular case; the outer row therefore radiate heat direct, and a continual current of air passes up and is heated between the two rows. As each strip is independent and connected to the circuit in parallel, any one can be replaced or removed without altering any connections. The smallest pattern of stove (Fig. 1) contains 12 strips, weighs 5lb, and takes six to eight amperes at 110 volts; the medium size contains 24 strips, and takes from 2 to 16 amperes at 110 volts, while the large size (Fig. 2) contains 48 strips and weighs 15lb. This and the medium size are fitted with the Prometheus regulator, enabling the stove to be used from quarter to full power in four steps. Under ordinary conditions the small size radiators will be sufficient

Digitized by Google

for heating rooms of from 700 to 900 cubic feet, the medium size for rooms of 1,400 to 1,800 cubic feet, the large size for rooms of 2,500 to 2,800 cubic feet capacity. The bases of the stoves remain quite cool, and they may therefore be used anywhere, and, as previously explained, they are practically instantaneous in their heating action when turned on. To give the stove a cheerful appearance when working, a ruby lamp is arranged behind the mica strips, and shines through and between them, shedding a cheerful light throughout the room.

Other applications for these strips, such as hot-combs for drying ladies' hair, hot-plates for use in the dining-room, foot-warmers, and the like, can easily be imagined, and they will doubtless entirely replace the existing cumbrous forms of heaters for these purposes—in fact, this invention only requires to be seen to be appreciated, and for new applications of same to be designed.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

319. Why is it not common to run compound dynamos with equalising cables coupling all series coils in parallel on town-lighting supply? Would not this be advantageous where many heavy motors were coupled to the lighting mains? Give reasons for and against.—ALEXANDER H. MCKAY.

320. In an alternate-current station where accumulators are charged by means of a direct-current dynamo driven by a synchronous alternate-current motor, what will be the increase in the cost per unit supplied due to the conversion and storage of the electrical energy and to capital charges on the additional plant?—P. T.

ANSWERS.

Question No. 313.—When testing an electric locomotive, both in the shop with a brake on the wheels and when pulling a train on the line, what are the quantities which have to be measured? In the latter case, does the draw-bar pull multiplied by the space moved over represent work comparable to the energy supplied to the motors?

Best Answer to No. 313 (*awarded* 10*s.*).—The simplest method of testing the approximate performance of an electric locomotive, and one especially useful when insufficient power is available, consists in measuring the pull exerted with the motor at rest with the full current passing through the armature and series field winding. The locomotive should be fixed down firmly, but with the wheels clear of the rails, etc., and a rope with a spring balance attached should be fastened to the rim or one of the spokes of one of the main wheels.

Let P = pull in pounds read on the spring balance;
R = effective radius at which the ropes acts, in feet;
r = radius of the tread of the locomotive wheels, in feet;
n = number of revolutions per minute of locomotive wheels;
A = current through motor when pull, P, is measured;
V = working voltage of the motor (V_a = internal armature volts);
g = gear ratio (if any) = $\frac{\text{speed of motor spindle}}{\text{speed of locomotive wheels}}$.

Then actual draw-bar pull of locomotive in pounds (per motor if more than one)

$$= \left(P \times \frac{R}{r}\right) - x,$$

where x is a certain small percentage for friction of locomotive bearings, slip between wheels and rail, and loss due to wind pressure on the locomotive. And

Actual horse-power developed at the motor spindle

$$= \frac{P \times R \times n \times 2\pi}{33{,}000} - y,$$

and

$$n = \frac{V_a \times A \times 7{\cdot}05}{P \times R \times g},$$

where y = a small allowance for core losses in the motor armature. These expressions are readily obtainable from first principles. (See S. P. Thompson's "Dynamo-Electric Machinery," fourth edition, p. 110.)

The next method of test is the ordinary brake test with the motor and car wheels running round at full speed, but the power developed being absorbed by some form of brake attached to the car wheel, instead of being allowed to draw the car along.

If P = pull in pounds read on the brake at a radius of R feet, and n = speed of car wheel in revolutions per minute. Then

Actual draw-bar pull of locomotive

$$= \left(P \times \frac{R}{r}\right) - z,$$

where z is a small amount of the pull lost due to slip between wheels and rail to wind pressure. And

Horse-power developed by motor

$$= \frac{P \times R \times n \times 2\pi}{33{,}000} + w,$$

where w is the loss in gearing (if any) and bearing friction between motor and car wheel.

The only method of test, however, which actually takes in all the conditions occurring in practice, consists in running the locomotive on a level line (or a line having a quite uniform grade) dragging a train whose weight can be adjusted as desired.

The drag of the locomotive on the train (draw-bar pull) should be measured by means of a special spring balance (whose motions are strongly damped by means of a dash-pot, or similar arrangement, so as to allow steady readings to be obtained in spite of small inequalities on the line) which forms part of the coupling between locomotive and train.

The speed of the train should be measured by means of an accurately calibrated tachometer carried on the locomotive, and also, if possible, by direct measurement with a stop watch over a measured piece of the line. The difference between these two measurements will be the slip between rails and wheels. At the same time the average input at the motors in volts and amperes should be measured.

If P = true draw-bar pull of locomotive as measured on the balance;
S = actual speed of train along the line in feet per minute;
A and V the amperes and volts respectively. Then

Actual horse-power transmitted by the locomotive to the train

$$= \frac{P \times S}{33{,}000}.$$

And actual electrical horse-power put into the motors

$$= \frac{A \times V}{746}.$$

And the ratio $\frac{\text{Actual H.P.}}{\text{E.H.P.}}$ is the true over-all efficiency of the locomotive.

The commercial efficiency of the motors themselves will be several per cent. higher than this, for to "actual horse-power transmitted to train" must be added the horse-power required to move the locomotive itself + the loss in the gearing and car bearings + loss due to slip + loss due to wind pressure. This "commercial efficiency of motor" is, however, of minor importance compared with the actual over-all efficiency of the locomotive given above.—Q.]

Question No. 314.—In working shunt-wound motors from 110-volt circuit nominal, the voltage sometimes drops to 100. If the supply of current is practically unlimited, as from a large generating station, how will the voltage drop affect the working of the motors, electrically and mechanically?

Best Answer to No. 314 *(awarded* 10*s.).*—In considering the behaviour of a motor under variations of the impressed E.M.F., the following equations are of fundamental importance:

$$T \propto C F;$$

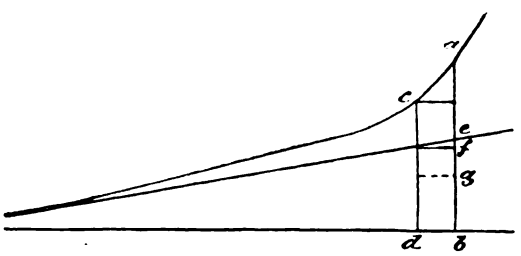
$$C = \frac{E - e}{r} \propto E - e;$$

$$e = \frac{N}{60} F \tau 10^{-8} \propto F N;$$

where T = torque;
C = armature current in absolute units;
E = impressed E.M.F.;
e = back E.M.F.;
F = total magnetic flux;
τ = turns in armature winding;
r = armature resistance;
N = revolutions per minute.

It may be supposed that the load on the motor is constant; hence the product, C F, is also constant—that is, the action of the motor under variations of impressed E.M.F. will be such as to maintain C F at its previous value.

Two cases may be considered: (*a*) when the motor has its magnets fully saturated at the normal E.M.F.; (*b*) when the magnets are excited to a point upon or below the knee in the induction curve. In case (*a*) any small variation of the exciting E.M.F. and current produces so relatively small a change of flux that it may be ignored, and a fall of the magnitude stated in the question may be taken to produce no alteration in F. On the other hand, the quantity $E - e$, and consequently the current, C, is reduced. The motor at once slows down until e is reduced by an amount equal to the fall in E, thus maintaining the value of C F. Thus a fall of $\frac{1}{n}$th in the supply volts produces a fall of $\left(\frac{1}{n} \cdot \frac{E}{e}\right)$th in both back E.M.F. and speed. In case (*b*) a fall in exciting E.M.F. reduces the flux to some value F′; the percentage fall of flux will, however, be somewhat less than the percentage drop of E.M.F. This reduction of flux brings down the back E.M.F. independently of fall in speed. As, however, it does not fall proportionally to E, and as the current must now be greater than before to keep C F constant, some drop in speed will occur. The motor is nevertheless in this case to a large extent self-regulating, and if well designed the speed reduction should be small. The action of the motor under various excitations and E.M.F.'s is clearly seen and found numerically by plotting the diagram shown. The



upper curve is the supply E.M.F. plotted with values of the total flux as abscissæ. The lower straight-line curve has the same abscissæ, and the back E.M.F. at the normal speed as ordinates. Since this E.M.F. is proportional to speed, the ordinates may to a suitable scale represent speed. If the impressed E.M.F. be $a\,b$, the back E.M.F. is $e\,b$. Let, now, the impressed E.M.F. fall to $c\,d$, then the fall in back E.M.F. due to the weaker flux is $e\,f$, and the speed drops by an amount (on the speed scale) equal to $f\,g$, the length, $e\,g$, being equal to the vertical distance between a and c. The influence of armature reaction has not been considered, but the back turns, which in a motor assist the field, tend to diminish the power of self-regulation. As regards e, it will be noted that the nearer e is to E at normal speed, the less will be the speed variation with changes in the latter. ZERO.

Answer to No. 314 *(awarded* 5*s.)*—Taking it for granted that the average load of the motor remains unchanged whatever the pressure of supply, the probable effect of a drop in voltage upon a shunt-wound motor will be as follows: (1) weaker field magnets; (2) increase in the current passing through the armature and a possible heating up of the machine in consequence; (3) probable decrease in the speed of the motor; (4) increased tendency to spark at the brushes.

1. The motor being shunt wound, we may consider its field coils as connected directly across the mains; so that if V = voltage of supply, r = resistance of shunt, S = number of coils in series, then $\frac{V}{r} \times S$ = magnetising ampere-turns on field magnets. Any reduction, therefore, in V reduces the exciting current and consequently the strength of field. Just what reduction takes place in this respect depends upon the magnetisation curve of the material used in the field magnets and upon the degree of saturation normally obtained. With soft iron highly magnetised, the drop may be comparatively small; with steel under the same circumstances, rather more; but a large reduction will probably take place if the field magnets were originally under-magnetised.

Upon the assumption that the nature of the load is the same throughout, the torque required in the armature with the reduced E.M.F. will be the same as before. If i_a = current in armature, N = magnetic flux, C = number of conductors in armature, T = torque, then $T = i_a \frac{CN}{2\pi}$ in certain units; or $i_a = \frac{2\pi T}{CN}$, from which it will be seen that any reduction in N will necessitate a corresponding increase in i_a if we are to maintain the torque constant; but we previously pointed out that N is reduced under the lower voltage, therefore we shall have a greater current flowing through the armature (2).

This current flowing through armature $= \frac{V - v}{R}$, where v = back E.M.F. of motor, and R = resistance of armature; v varies as n C N, where n = speed of motor, other things remaining constant; therefore if V is reduced, v must be reduced in like manner in order that $\frac{V - v}{R}$ may remain unaltered; and if N remains constant, n must be reduced in order to bring v down to this lower value. It was pointed out that a greater current was needed in the armature with the reduced voltage than before—*i.e.*, $\frac{V - v}{R}$ must have a higher value, and in order to obtain this, v, and consequently n, must be still further reduced. In other words, the drop in voltage independently tends to lower the speed of motor, and the consequent increase of current necessary tends still further to lower it—this is upon the assumption that N remains constant. We have shown, however, that N does not remain constant, but suffers a reduction, which reduction tends to oppose the lowering of the speed, consequently you have the two factors before mentioned tending to lower the speed, and one (the weaker field) tending to increase it—the net result will probably be a slight reduction in the number of revolutions per second with the reduced voltage (3).

The fact as to whether a motor will run sparklessly or not, depends upon whether the local field is strong enough to reverse the direction of the current in the coil which is short-circuited under the brushes previously to its becoming one of the series on the other side of the brush through which the current is running in this reverse direction; the stronger the current flowing, the greater the field necessary for conversion. Now we have, as results of the reduced voltage, a weaker field and a larger armature current, both of which tend to oppose sparkless running; and we have still further the field due to the armature stronger relatively to that of the field magnet, and this

Digitized by Google

means an increased distortion of field and a probable weakening of the same just at the point where it is most required to reverse the current in the short-circuited coil. The increased current also has an increased demagnetising effect upon the field magnets, and any movement of the brushes backward in order to obtain a sparkless position tends to increase this demagnetising effect and still further weaken the field; so that the effect of the reduction in voltage may be to make it impossible to get the motor to run sparklessly (4).

In conclusion, if the motor is well designed and has relatively very strong field magnets, normally highly magnetised, the tendency to spark under the reduced voltage will be reduced to a minimum, and it may be quite possible at periods when the pressure is low to insert a resistance in the field circuit, thus counteracting any fall in speed within certain limits. The armature conductors will, however, need to be designed upon a liberal scale in order to carry the increased current without undue heating. The motor will not be so efficient, however, as when running at the voltage for which it was designed, because, among other things, the $C^2 R$ losses will be increased without a corresponding increase in the work performed.—W. G. M.

Answer to No. 314 (*awarded* 5*s.*).—A method of examining the effect of running shunt motors at a lower speed than designed for will be to assume a motor of, say, 6 h.p. built for 110 volts, and which may afterwards be required to work at 100 volts. Supposing efficiency to be 87 per cent., it would require an input of 5,140 watts. At 110 volts this = 46·75 amperes; at 100 volts this = 51·4 amperes.

Let armature resistance be ·06 ohm. The copper loss of armature at 110 volts = 124 watts; the copper loss of armature at 100 volts = 150 watts (probably the latter figure would be increased owing to increase of resistance through higher temperature rise). These figures show an increase of temperature of about 12 per cent. when working at 100 volts. (The slight gain, through the hysteresis loss being a little lower at 100 volts, is practically negligible.)

Beside the heating effect, there is another important point to consider—viz., sparking. In the case under consideration the cross ampere turns are increased by about 10 per cent. at the lower E.M.F., the gap density being also slightly lower. Both these results would, of course, tend to increase the sparking. In a well-designed machine, however, neither the sparking or heating should be very much increased, at any rate to an injurious extent, by a reduction of voltage as required in present instance.

As regards alteration of speed, if the excitation was the same for both voltages it would be lower at the 100 volts in the ratio of

$$\frac{110 - (46\,75 \times \cdot 06) = 107\cdot2}{100 - (51\cdot4 \times 06) = 96\,9} = \text{approx. 11 per cent.}$$

but being excited at 100 volts the percentage of variation of speed would not be so great as this. To obtain difference of speed through variation of shunt voltage, we should find it necessary to refer to a magnetisation curve of each of the motors, as the alteration of speed through weaker field depends a great deal on the portion of curve at which motor is designed for. If we are working off the "flat" of the curve, or, in other words, if the magnets are approaching saturation at 110 volts, we should have but a slight increase of speed when lowered to 100 volts; but, on the other hand, if the line density in magnets is comparatively low at the higher voltage, we should find a much greater variation of speed.—J. W. B

Answer to No. 314 (*awarded* 5*s.*).—Firstly, this drop in voltage would reduce the field exciting ampere-turns by 10 per cent., and this would reduce the flux through the armature by from 4 to 8 per cent., according to the state of saturation of the magnet iron. If the volts across the armature remained unchanged, this would cause a corresponding rise of 4 to 8 per cent. in the speed, but since these volts also drop 10 per cent., the net result on the speed will be a drop of from (10 − 4) = 6 per cent. to (10 − 8) = 2 per cent.

Secondly, there would be a certain change (usually an increase) in current to enable the motor to continue to give out the necessary power at the lower voltage. The actual change in current depends on the nature of the load on the motor. If this load consists of a lathe or similar machine, in which, at least for small changes in speed, the horse-power required is almost exactly proportional to the speed, the current will increase by something less than 10 per cent.—*e.g.*, if the 10 per cent. drop in voltage reduced the speed 6 per cent., the current would increase only 10 − 6 = 4 per cent. If, on the other hand, the load consists of, say, a centrifugal pump or fan, in which the power required falls off much more rapidly than in proportion to the speed, there will probably be no increase in current, and may even be a drop. If desired, the speed could, of course, be kept constant by inserting a small amount of resistance in the shunt at 100 volts, and in this case the current through the armature would always be 10 per cent. higher at 100 than at 110 volts. This small increase in current should not cause any difficulty with a properly designed motor, though the temperature rise of the armature would be slightly increased. If, however, the motor is one designed with very little margin, the weakening of the field, occurring at the same time as an increase in the armature current, might cause sparking at the brushes, though not to any serious extent.—Q.

LEEDS ELECTRICITY ACCOUNTS.

The accounts of the Leeds electricity works for the year ended March 25, 1900, just issued, show a total expenditure on capital account of £307,522. Abstracts of the revenue account and general balance-sheet are appended:

BALANCE SHEET.

LEGAL INTELLIGENCE.

NATIONAL TELEPHONE COMPANY v. THE EXCHANGE TELEGRAPH COMPANY.

In the Queen's Bench Division on Wednesday, before Justices Lawrance and Kennedy, on the motion of Mr. Roskill, their Lordships directed that this action should not be in the paper before Dec. 1, both sides consenting to the postponement.

CLAIM BY THE LONDON ELECTRIC SUPPLY CORPORATION.

n the Westminster County Court on Tuesday, his Honour Judge Lumley Smith, Q C., heard the case of the London Electric Supply Corporation *v.* Butler, in which the plaintiff company sought to recover payment in respect of electric light supplied to the defendant, a florist carrying on business at Westmoreland-road, Walworth.

Plaintiffs' representatives said the light was supplied to the order of the defendant when he was carrying on business on his own account, but he had since sold the place to his son, and had made no attempt to pay the plaintiffs' claim, although he was in a good position to do so, and judgment had been obtained against him.

His Honour made an order committing the defendant to prison for 12 days in default of the amount due being paid within a month.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY v. FISHER.

This was an application by the plaintiff company to enforce payment of an account in respect of electric light supplied to the defendant, a restaurant keeper carrying on business at Broad-street, Golden-square.

Evidence was given to the effect that the light was supplied to the order of the defendant, and that when application was made for payment he put the matter off with various excuses.

The **Defendant** appeared, and said he was not in a position to pay.

His Honour said it was ridiculous for people to indulge in the luxury of electric light, and then find out that they could not pay for it. There would be an order of committal for 12 days in default of payment by Dec. 1.

DUNDEE TRAMWAY AND CARRIAGE COMPANY.

The First Division of the Court of Session (Glasgow) have granted the petition of the Dundee Tramway and Carriage Company for confirmation of resolutions altering their memorandum of association. The Corporation of Dundee having purchased the tramway plant, the company ceased to operate the tramways in the city. The company had, in connection with their tramway business, conducted and still conduct an omnibus business and hiring business and the carriage of goods, and own large premises in Dundee and Downfield for the carrying on of these businesses. It is in order to carry on these businesses more effectually that the alterations sought to be confirmed were required. The petition was remitted to Mr. J. Smith Clark, S.S C., Edinburgh, for report, and in granting the petition the Court gave effect to certain amendments of the new articles proposed by the reporter.—*Glasgow Herald.*

COMPANIES' MEETINGS AND REPORTS.

CUBA SUBMARINE TELEGRAPH.

The half-yearly meeting was held on Wednesday at the offices, 58, Old Broad-street, Mr. Charles W. Parish presiding. The report showed that the traffic receipts for the first half of this year had fallen to £13 177, from £18,823 in the corresponding period of 1899, due partly to the cessation of the war, and partly to competition and subsequent low rates. In addition to the actual traffic earnings, £2,158 had been received as interest on investments, etc., making the total revenue £15,336. A sum of £2,000 had been carried to the reserve fund, the dividend on the preference shares required £3 000, and from the balance the Board were able to propose a dividend at the rate of 5 per cent. per annum on the ordinary share capital, leaving £5,204 to be carried forward, as compared with £5,165 brought forward from Dec. 31 last. The item of £8,174 for repairs to the cables damaged during the Spanish-American war was still outstanding.

The **Chairman** said that the negotiations which her Majesty's Ambassador was carrying on on the Company's behalf with the United States were still proceeding, but he was afraid that until the American elections were over and the President elected, they could not hope for any definite news The lawsuit between this Company and the West India and Panama Company in regard to the construction of part of their agreement was still before the courts. The result of the trial in the High Court was completely in this Company's favour, but the West India and Panama Company had given notice of appeal, which would probably be heard at the end of this year or early next year.

Mr. George Keith seconded the motion, which was agreed to, and the proposed dividends, at the rates of 10 and 5 per cent. on the preference and ordinary shares respectively, were confirmed.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MANUFACTURING.

At the meeting at Winchester House on the 24th inst. Mr. H. F. Jackson presided.

Mr. Fitzgerald, the late chairman, strongly criticised the balance sheet, and proposed that the report be referred back with the request that the accounts should be made up in the same way as formerly, and submitted to an adjourned meeting to be held one month hence.

Mr. A. H. Baker seconded the amendment.

After a long discussion, the amendment was lost by a very large majority, and the report adopted. A poll was demanded.

We note some correspondence in the financial papers on the subject. Want of space, however, prevents us from going into the matter at present.

WESTERN TELEGRAPH.

The directors' report for the half-year ended June 30 shows revenue of £230,434 and working expenses of £80,579. After providing £11,031 for debenture interest and sinking fund and £3,210 for income tax, a balance remains of £135 613. To this is added the sum of £6,790 brought forward from Dec. 31 last, making a total of £142 404. A quarterly interim dividend, amounting to £31,189, has been paid and £50,000 transferred to the reserve fund. The directors recommend the declaration of a final dividend of 3s. per share, making, with the interim dividends, a total dividend of 6 per cent. for the year, and also the payment of a bonus of 2s. per share—both free of income tax—leaving a balance of £8,571 to be carried forward. The Company having acquired an interest in the capital of the River Plate Telegraph Company, Limited, the Western directors will join the Board of the River Plate Company. Four per cent. debenture stock has been constituted to the amount of £400,000. Of this amount £348,777 has been allotted to the late holders of the same amount of 4 per cent. debenture stock of the Western and Brazilian Telegraph Company in lieu of their being paid off at par. The balance remains at present unissued. Additional cables have been successfully submerged between Para and Rio de Janeiro, and are being continued from the latter city to Monte Video.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Shoreditch.—The Vestry are inviting tenders for various plant. Tenders by Nov. 20. Details in our advertisement columns.

St. Albans.—The Corporation invite offers for their electric lighting provisional order. Details in our advertisement columns.

Lowestoft.—The Corporation invite tenders for wiring the town hall. Tenders by Nov. 2. Details in our advertisement columns.

Heywood —The Corporation invite tenders for wiring premises in Heywood. Tenders by Oct. 31. Details in our advertisement columns.

Belfast.—The Gas and Electric Committee invite tenders for various plant. Tenders by Nov. 23. Details in our advertisement columns.

London County Council.—The Council invite tenders for the supply, for one year from Jan. 1 next, of engineers' goods and electrical stores. Tenders by Oct. 29.

Palma —The Municipality of this town, in the province of Baleares, Spain, invite tenders for the installation and maintenance of 60 arc lamps. Tenders by Oct. 30.

Swansea.—The Corporation invite tenders for the supply of electricity meters, demand indicators, and main fuses. Tenders by Oct. 29. Details in our advertisement columns.

Breslau.—The Harbour Authorities invite tenders for electric cranes. Specifications are to be obtained from and tenders addressed to Hafenbauamt, Breslau, Germany, by Nov. 2.

Ayr.—The Corporation invite designs, specifications, and tenders for electric tramway cars, with trucks and complete electrical equipments. Tenders by Nov. 1. Details in our advertisement columns.

Pemberton —The Council invite tenders for boilers (preferably Lancashire), engines and dynamos, battery, switchboard, crane, and conductors. Tenders by Nov. 8. Details in our advertisement columns.

Digitized by Google

Dundee.—The Combination Parish Council invite tenders for the wiring for electric lighting of new offices at West Bell-street. Plans, etc., may be obtained from Mr. William Alexander, city architect, Dundee. Tenders by Oct. 27.

Grantown-on-Spey.—The Commissioners of the burgh invite tenders from electric light companies to supply electric light for public and private consumption within the burgh. Tenders by Nov. 6. Details in our advertisement columns.

Stavanger (Norway).—Tenders are invited for an electric installation for the supply of energy from the Alterig Waterfalls, which are about 25 miles from the town. Tenders may be addressed to the Municipal Authorities by Jan. 2, 1901.

Wolverhampton.—The Tramways Committee invite tenders for erection of car depôt, paint and repair shops, etc., at Cleveland-road. Plans, etc., may be seen at the office of Mr. J. W. Bradley, C.E., M.I.M.E., borough engineer, Wolverhampton. Tenders by Nov. 19.

Glasgow.—The Executive Committee invite tenders for the wiring for arc and incandescent lighting and electric motors at the Glasgow International Exhibition, 1901. Full particulars can be had on application to Mr. Thomas Young, the engineer, 4, West Regent-street, Glasgow.

Lowestoft.—The Corporation invite tenders for the supply and erection of two water-tube boilers and fittings, economiser, etc., pipework, etc., in engine and boiler house, and one 250-kw. steam dynamo (vertical enclosed high-speed engine). Tenders by Nov. 2. Details in our advertisement columns.

Leeds.—The Leeds Tradesmen's Benevolent Institute invite tenders for the installation of electric light required in alterations and additions to 41, Park-square, together with three shops and business premises, Park-lane, Leeds. Plans, etc., can be obtained from Messrs. Butler, Wilson, and Oglesby, architects, 12, East-parade, Leeds.

Devonport.—The Corporation invite tenders for the erection of electricity works buildings and works in connection with the new buildings to be erected on Newport Quay, Newport-street, East Stonehouse. Drawings, etc., may be seen on application to the Borough Electrical Engineer, Technical Schools, Devonport. Tenders by Nov. 2.

London (City).—The Streets Committee of the Corporation invite tenders for the hiring of a mechanically-driven dust-cart for collecting and removing the dust, trade refuse, and street sweepings from the City to the Corporation's depôt at Lett's Wharf, Commercial-road, Lambeth, S.E. Tenders by Nov. 10. Details in our advertisement columns.

Kendal.—The Corporation invite tenders for building engine-house, boiler-house, accumulator-house, chimney shaft, offices, etc., in connection with the electric lighting station to be erected at the gasworks, Kendal. Specification, etc., may be seen at the office of the engineer, Mr. T. N. Ritson, A.M.I.C.E., Gas Offices, Parkside-road, Kendal. Tenders by Oct. 29.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul-General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Alterig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

RESULTS OF TENDERS.

Killarney.—The Council have accepted the tender of Mr. Santry for the installation of 10 lamps at £52. 12s. 5d., and for lighting, etc., £2. 17s. 6d. per lamp per year.

Aberdeen.—The Tramways Committee have accepted tenders for 12 double-deck cars for the Beach and Woodside electric routes at a total cost of about £9,000, or £625 per car.

Barnsley.—The Corporation have placed with D. Bruce Peebles and Co. an order for a 600 h.p. generating set of their P.P.P. combined lighting and traction type. This will consist of one of that firm's machines direct coupled to a Willans engine.

Aberdeen.—The Town Council have accepted the tender of J. Leith, jun., 3, Cattofield-place, at £9,904. 15s., for the supply of materials and the construction of works in connection with the laying down of the permanent way of new electric tramways.

Middleton (Lancs.).—The Corporation have received the following tenders for the buildings required for electricity station: R. Partington and Son, The Lodge, Middleton (accepted); F. Cable, Durnford-street, Middleton; W. Pollitt, Burton street, Middleton; T. Jackson and Sons, Manchester Old-road, Middleton; J. Parker, Peter-street Sawmills, Blackburn; J. Tinline, Parker-street Sawmills, Bury; A. Coward, Tonge Moor-road, Bolton; J. and D. Blunn, Limited, Villa-road, Bury.

Southampton.—The Harbour Board have received the following tenders for a 30cwt. portable electric crane:

J. Booth and Bros., Limited, Leeds	£1,325
Chatteris Engineering Works Company, Chatteris	1,150
Bow, McLachlan, and Co., Paisley	1,100
Fullerton, Hodgart, and Barclay, Limited, Paisley	970
Stothert and Pitt, Limited, Bath	950
Southgate Engineering Company, Limited, New Southgate	798
Clayton Engineering and Electrical, etc., Company, Limited, Newton, Hyde (accepted)	735

Brighton.—The Corporation have received the following tenders for the supply and delivery of the following—viz.: (1) 2 000 tons steel girder tramrails (including curve rails), 78 tons of steel fish-plates, and 90 tons of steel joists; (2) 25 electric motorcars (in three sections):

1.—Steel rails, &c.

E. Le Bas and Co., 18, Billiter-street, London	£15,718 0 0
Westfalisch Stahlwerkes, Bochum, Westphalia	16 975 18 0
Witting Bros., 49, Cannon-street, London, E.C.	16,941 13 0
Bolckow, Vaughan, and Co., 16, Philpot-lane, London, E.C. (accepted)	18,397 0 0
Barrow Hematite Company, Barrow-in-Furness	18,564 0 0
R. White and Sons, Widnes, Lancashire	18,564 10 0
Leeds Steelworks, Hunslet, Leeds	18,970 0 0
W. David, Swansea	19,700 0 0

Note.—Of above tenders, only those of Bolckow, Vaughan, and Co. and W. David comply strictly with the specification.

2.—Motorcars—57-passenger car.

British Westinghouse Company, 5, Norfolk-street, Strand, W.C. (each)	630 0 0
British Thomson-Houston Company, 83, Cannon-street, E.C.	647 17 0
British Schuckert Company, Clun House, Surrey-street, Strand, W.C.	685 0 0
Witting Bros., Limited, 49, Cannon-street, E.C.	765 0 0
Dick, Kerr, and Co., 110, Cannon-street, E.C.	724 0 0
Brush Electrical Engineering Company, 49, Queen Victoria-street, E.C.	728 0 0

50-passenger car.

British Westinghouse Company (each) (accepted)	619 10 0
British Thomson-Houston Company	637 7 0
British Schuckert Company	675 0 0
Witting Bros., Limited	689 0 0
Dick, Kerr, and Co.	696 0 0

London, N.E.—The Electric Lighting Commitee of the Hackney Vestry have recommended the following tenders for acceptance:

Cole, Marchant, and Morley, Limited, condensing plant	£4,749 0 0
Klein Engineering Company, Limited, cooling apparatus	1,960 0 0
Alton and Co., pipework and valves	5 065 0 0
Worthington Pumping Engine Company, feed pumps	753 0 0
S. Z. de Ferranti, Limited, switchboard and instruments, boosters and motors, etc. (Part 1)	2 976 10 0
Johnson and Phillips, ditto (Parts 2 to 5)	2,160 0 0
Johnson and Phillips, public arc lamps and switchboard	5,248 18 6
Chamberlain and Hookham, Limited, house meters	3,632 10 0
Higginbottom and Mannock, overhead travelling crane	638 0 0
Easterbrook, Allcard, and Co., workshop equipment	772 2 4
W. T. Allen and Co., 132, Queen Victoria-street, E.C., arc lamp pillars (per pillar)	13 5 0

London, N.E.—The Hackney Vestry have received the following tenders for electricity mains:

Trenching.

Siemens Bros. and Co., Limited	£12,899 6 8
British Insulated Wire Company, Limited*	14,339 0 0
Western Electric Company	14,982 0 0
Callender's Cable and Construction Company	15 202 0 0
Henley's Telegraph Works	18,536 16 8
W. T. Glover and Co.	11,073 6 8
Callender's Cable and Construction Company (alternative without lead)	15,202 0 0

Troughing.

Melton (Suffolk).—The Visiting Committee of the Suffolk County Asylum have received the following tenders in connection with the wiring and fittings for the electric lighting of the asylum at Melton:

Baily, Grundy, and Barrett, Limited, Cambridge	£5,900	5	5
J. E. Lester, Leicester	5 834	0	0
A. Emanuel and Sons, Limited, Manchester-square, W.	4 860	0	0
T. H. Wathes, Leicester	4 285	2	6
Lighting Corporation, Limited, Bloomsbury	4,252	18	0
F. Suter and Co., Limited, Berners-street, W.	3 853	6	0
F. Troy and Co., Finchley	3 648	6	6
Hall and Hackblock, Ipswich	3,633	15	4
Dawson, Roberts, and Co., Stalybridge	3,609	9	5
Maple and Co., Tottenham Court road	3,432	17	6
Anglian Engineering Company, Limited, Stowmarket	3 417	7	6
J. Finlay and Co., Limited, Glasgow	3,375	16	7
Walsall Electric Company, Limited, Walsall	3,337	14	2
T. Scott Anderson, Sheffield	3,300	0	0
Shalders and Davis, Southampton	3,255	13	2
National Electric Wiring Company, Limited, Newington-butts	2 867	0	0
W. J. Fryer and Co., Limited, Sloane square, S.W.	2,824	14	8
G. N. C. Mann and Co., Norwich (accepted)	2,740	18	9

BUSINESS NOTES.

LIGHTING AND GENERAL.

Ilford.—The Urban District Council will shortly invite tenders for free wiring.

Leominster.—Telegraphic communication is being made between Leominster and Hatfield.

Worcester.—The Town Council have adopted a proposal to build an additional electricity generating station.

Removal.—The Sturtevant Engineering Company, Limited, have removed their offices to 147, Queen Victoria-street, E.C.

Wisbech.—The Town Council intend to apply for a provisional order under the Electric Lighting Acts. Advertisements are being prepared.

Sevenoaks.—The Urban District Council have approved a draft supplemental agreement with the Electrical Power Distribution Company, Limited.

Beckenham.—The Urban District Council have passed a resolution authorising the clerk to sign agreements with householders in respect of electric wiring.

Lichfield.—The Council will at a meeting on the 9th prox. discuss the advisability of applying for a provisional order under the Electric Lighting Acts.

Northfleet.—The District Council have decided to take the necessary steps to obtain a provisional order for the electric lighting of the district in the ensuing session of Parliament.

Sleaford.—Mr. M. K. North has held a public enquiry at Sleaford with reference to the borrowing of £7,000 by the Sleaford Urban District Council for an installation of the electric light.

Calcutta Electric Supply Co.—The directors have declared an interim dividend on the share capital of the Company at the rate of 3 per cent. per annum for the half-year ending June 30 last.

Eccles.—Colonel J. T. Marsh, R.E., has held an enquiry into an application for power to borrow £5,308 for purposes of electric lighting, being money expended in excess of the original estimate.

Earsdon.—The Seaton Delaval Co-operative Society have offered to supply electric light and lay the plant from the Seaton Delaval boundary to Holywell Bank Top. They would lay down the plant for £180.

H. A. C. Barracks.—The headquarters of the Honourable Artillery Company have been wired for the electric light by Messrs. Donnison, Berlyn, Sillem, and Co., of London and Liverpool.

Huddersfield.—The last report to the Electricity Committee shows an increase of 25,998 in the units metered in August and September, or 27½ per cent. more than in the corresponding months of last year.

Ashton-in-Makerfield.—Application is to be made for an electric lighting provisional order to authorise the Urban District Council to supply electrical energy for public and private purposes within their district.

Kingsburgh Motor Construction Co.—This Company has been registered at Edinburgh with a capital of £50,000 in £5 shares, the object being to acquire and carry on the Madelvic Motor-Carriage Works at Granton, etc.

Boston.—At the meeting of the Paving and Lighting Committee on Monday the question of the lighting of the town by electricity was discussed, and it was decided that an expert should be invited to visit the town and make a report.

Frome.—The Urban District Council have adopted a report of Mr. F. H. Medhurst as to the establishment of electric lighting works in the town, and have decided to proceed with the matter and obtain the necessary provisional order.

Melksham.—A number of workmen are now at work laying the electric cable through the principal streets under the supervision of an electrical expert, Mr. Poolley, of the firm of Messrs. Glover and Co., cable manufacturers, Manchester.

Bournemouth.—With regard to the proposed purchase of the electric light undertaking, a conference has been arranged between representatives of the Town Council and of the Bournemouth and Poole Electricity Supply Company, Limited.

Alnwick.—Arrangements have been completed between the Postmaster-General and the Urban District Council for the making of the telephone trunk line to Alnwick. The refuse destructor and electric lighting questions are still undecided.

Castner-Kellner Alkali Co.—The directors announce an interim dividend on the original capital, as well as on the new capital allotted to the shareholders of the Aluminium Company, at the rate of 8 per cent. per annum for the six months ended 30th ult.

Chester.—The distributing main for supplying energy for public and private lighting in Gladstone avenue, Whipcord lane, Charlotte-street, Catherine street, and Cambrian-view is to be extended, and the existing gas lamps converted, etc., at an estimated cost of £280.

Stratford-on-Avon.—Alderman Hawkes, Messrs. Holtom, Park, Flower, and North have been appointed an Electric Lighting Committee, the Council having decided to apply for a provisional order to supply electricity for lighting and traction purposes within the borough.

Normanton (Yorks).—A special meeting of the Council has been convened for an early date in November to finally decide whether to seek an electric lighting order provisional. Some of the other West Riding councils are awaiting the result of this meeting before taking action.

Edinburgh.—At the last meeting of the Electric Lighting Committee of the Town Council, it was reported that there had been applied for from Oct. 4 to 18 2,337 8 c.p. lamps for lighting purposes and 112 h.p. motors, equal to 2,928 8 c.p. lamps, making a total of 5,625 8-c.p. lamps.

Aylesbury.—At the last quarterly meeting of the Bucks Standing Joint Committee letters from the General Post Office and the National Telephone Company, Limited, as to the terms of connecting police stations were submitted, but the terms offered were not entertained by the committee.

Eastbourne.—Application is to be made to the Local Government Board for power to borrow the sum of £31,912 for the erection of a new electric light station at Roselands, new transformers, mains, etc., as set forth in Scheme 2 of Mr. Hawtayne's report, dated April 9, 1900, and adopted by the Council on May 3, 1900.

Brighton.—In order that the Corporation may be in a position to place their exchange wires underground, it will be necessary, in accordance with the Telegraph Act, 1892, for the Postmaster-General to delegate to them his statutory powers of constructing telegraphic works. The Council are asking the Postmaster-General to do so.

Colwyn Bay Electric Light and Power Co.—This Company has been registered with a capital of £3,000 in £1 shares (1,000 preference), the object being to adopt an agreement with T. S. Jones and R. H. Jones, and to carry on at Colwyn Bay the business of electric light and power producers, manufacturers, and fitters of electrical appliances, etc.

Royton.—At a special meeting of the District Council held on Monday it was decided to apply in the next session of Parliament for provisional orders enabling the Council to supply electricity for all public and private purposes within and throughout the whole or any part of the district, and also empowering the Council to take over and work tramways.

Barry.—The District Council intend to proceed with their application for an electric lighting provisional order. The application received from the Penarth Electric Lighting Company to provide the Barry district with electric power has been rejected, the Council being of opinion that such power, for the purposes of the town, should be provided by the local authority itself.

Mansfield.—The Town Council on Friday passed a resolution to the effect that it was desirable to promote a Bill in Parliament excluding the loans for the purposes of the water and electric light undertakings from the sanitary loans, and containing provisions as to moneys to be raised for water and electric light purposes, and also modern and financial provisions with reference to loans.

Woking.—The price of the current has now been reduced as follows: for any number of units up to 20, 8d. per unit; and for each unit over 20, 7d. In addition to the above reduction, the Woking Electric Supply Company offers a discount to consumers whose consumption exceeds 150 units per quarter of ¼d. per unit; 250 units per quarter of ½d. per unit; 375 units per quarter of 1d. per unit.

Appointments Vacant.—The Corporation of Darlington are prepared to appoint an assistant engineer and a junior assistant engineer.—The Electric Lighting Committee of Bury invite applications for an assistant engineer at their generating works. Particulars of these and other vacancies relating to switchboard attendants, wiremen, and electricians will be found in our advertisement columns.

Castleford.—At a special meeting of the Council on Tuesday it was decided to support the scheme of the United Kingdom Tramway Light Railway, and Electric Lighting Syndicate. This is a scheme for electric lighting, with power for industrial purposes and for tramways, applicable to Castleford and the districts around, including Pontefract, Normanton, Whitwood, Featherstone, and Knottingley.

Digitized by Google

Evolution of Switch Gears.—Messrs. Johnson and Phillips have written to us referring to Mr. E. Warrilow's interesting articles, stating that they are the sole makers of the Proctor-Blaikie patent plug, which is mentioned as having been fixed on the Bristol Corporation switchboard. They add that they find no difficulty in keeping the size of the plug within quite moderate dimensions for very large currents.

Wormit.—Last week a meeting of householders was called by the directors of the Tayside Electric and Gaslight Company, Limited. Extracts were read from Mr. Tittensor's report upon the electric lighting plant at Wormit, presently the property of Mr. Alex. Stewart, builder, which it was proposed the company should acquire. A former proposal was referred to, and a committee was appointed to confer with the directors and report to a later meeting.

Pateley Bridge.—At a meeting held in the District Council-room, Pately Bridge, on Friday evening, for the purpose of discussing the advisability of introducing electricity for lighting purposes into the town, Mr. Boord occupying the chair, it was stated that there was sufficient surplus power at Mr. Wood's corn mill to supply the motive power, and to supply 750 8 c.p. incandescent lights. Mr. Harrison, of Ripon, estimated the cost at £2 000. Discussion followed, and a resolution favourable to the introduction of the electric light was passed.

West Bromwich.—On Thursday night a meeting of the West Bromwich Tradesmen's Association was held to consider the best and cheapest method of applying the electric light to the shops and offices of the borough. The Mayor (Alderman S. Pitt) explained the scheme, and said it was the intention of the Council to light the principal streets with electricity, and probably the electric tramcars would be running in about 12 months' time. A resolution approving of the scheme, and recommending the tradesmen to adopt electric lighting, was carried.

New Issue.—An issue of 19,900 6 per cent. cumulative preference shares of £5 each is being made by the Electric and General Investment Company, Limited, which has an authorised share capital of £200,000, divided in 20 000 ordinary, 19,900 preference, and 100 founders' shares, all of £5 each. The net profits of the company, which was formed in May, 1890, to promote and develop undertakings, are certified in the prospectus to have averaged £14 713 per annum for the last 10 years The net profits for 1897-98, 1898 99, and 1899 1900 were respectively £27,719, £27,450, and £16,711.

Society of Arts.—We have received the syllabus of the course of four Cantor lectures to be delivered by Prof. J. A. Fleming on "Electric Oscillations and Electric Waves," at the Society of Arts on Monday evenings, Nov. 26, Dec. 3 10 and 17. The first lecture will deal with "Electric Oscillations," their production, the factors determining their frequency and energy, secondary oscillations, and magnetic and other effects produced by electric oscillations. Lecture II will deal with "Electric Resonance," the third lecture with "The Electromagnetic Medium," and the fourth with "Electric Waves."

Bermondsey.—Mr. William H. Vincent, M.I E E., borough electrical engineer at Ashton-under-Lyne, and formerly assistant engineer to the Metropolitan Electric Supply Corporation, has been appointed resident electrical engineer. There were 46 applications for the appointment. Tenders will be shortly invited for the supply of columns and arc lamps for the lighting of the public streets. The Vestry have decided to apply to the London County Council for a loan of £12,723 for the purpose of erecting the electric lighting buildings and the dust destructor, the tender for which was accepted by the Vestry at a recent meeting.

"General Electrical Progress."—The General Electric Company, Limited, have just issued No. 29 of this catalogue. It contains a new "loop-in" ceiling rose specially designed for the looping-in system of wiring, suitable for 220-volt circuits; a new B.C. adaptor with fuse terminals; a portable medical battery, comprising six No. 3 sack cells in varnished pine box and cell-selecting switch, enabling the current to be increased by the addition of one cell at a time, or correspondingly decreased; and a slide rheostat suitable for use with accumulators or primary batteries, any kind of which may also be used for small medical lamps on 100 volt circuits.

Pontefract.—A scheme by the United Kingdom Tramway, Light Railways, and Electric Syndicate, Limited, to supply electrical energy, through one power station, for lighting, tramways, and power purposes for the districts of Glasshoughton, Brotherton, Ferrybridge, and Fryston, will come before the District Council at their next meeting. The District Council have invited the engineers, Messrs. Richardson and Lemaitre, of Leeds, to meet the Council and explain the details of the scheme. The syndicate propose to erect the works, giving the Council the option of purchase at the end of each recurring seven years. They would supply light at 5d. per unit for private purposes, and 4d. per unit for public; and power at 4d. per unit for the first hour and 1d. per unit for each succeeding hour.

Worthing.—The Council have authorised the Electric Lighting Committee to proceed with the erection of a generating station and alterations to existing buildings in connection with the electric lighting station, and have engaged Mr. Davison, of Worthing, as general foreman on the works. Tenders will be invited for cartage work and for the supply of 160,000 bricks, etc. With reference to the communication received from Mr. W. A. Taylor on the subject of the provision of effective smoke-consuming apparatus in connection with the generating station, after consulting the engineers thereon, the Electric Lighting Committee report that they are satisfied that adequate provision will be made for the due and proper consumption of smoke at the works when the same are in operation.

London Gazette.—The estate of E. L Joseph, 109, Brondesbury-villas, Brondesbury, has been released from trusteeship. Notices of intention to apply for provisional orders under the Electric Lighting Acts, 1882 and 1890, have appeared from the Wisbech Corporation and the Gainsborough Urban District Council. The East Stonehouse Urban District Council have notified their intention to transfer their order to the Devonport Corporation The North Metropolitan Electricity Supply Company have notified that the necessary arrangements are being made for the supply of electricity (*a*) to the authority for lighting streets and bridges or public places, (*b*) to all local authorities, persons, or companies being authorised undertakers under the statutory powers within the districts of the poor-law unions of Hendon, Barnet, Edmonton, Ware, Hertford, Welwyn, St. Albans, and Chingford.

Stock Exchange.—The Stock Exchange Committee have appointed Nov. 13 as a special settling day for Telegraph Manufacturing Company, Limited, further issue of 5 000 shares of £5 each, fully paid, Nos. 20,001 to 25,000. The committee have also ordered the undermentioned securities to be quoted in the official list: Folkestone Electricity Supply Company, Limited, 10,000 ordinary shares of £5 each, fully paid, Nos 1 to 10,000; National Telephone Company, Limited, £500,000 4 per cent. debenture stock; and Telegraph Manufacturing Company, Limited, further issue of 5,000 shares of £5 each, fully paid, Nos. 20,001 to 25,000. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to British Electric Traction Company, Limited, further issue of 10,000 6 per cent. cumulative preference shares of £10 each, fully paid; and 15,000 ordinary shares of £10 each, fully paid.

Institution of Engineers and Shipbuilders in Scotland.—From the report of the council on the session 1899 1900, submitted at Tuesday's meeting, we note that the membership of the institution continues to increase. Eight meetings were held during the session, at which the following papers, among others, were read and discussed: "Lighthouse Engineering at Home and Abroad," by Mr. John A. Purves, D.Sc., F.R.S.E; "The Electric Wiring of Buildings," by Mr. W. A. Chamen; and "The Action of Electric Tramway Currents on Submarine Telegraph Cables and other Electric Circuits," by Prof Andrew Jamieson, F.R.S.E. The council is arranging an international engineering congress, under the presidency of Lord Kelvin, in connection with the Glasgow International Exhibition of 1901. The leading engineering and kindred societies have already accorded their hearty support to the congress. An influential London committee has been formed, and the congress gives every promise of being a perfect success.

"Manual of Electrical Undertakings."—The fifth edition of Garcke's "Manual of Electrical Undertakings" will be published about Nov. 1 next. It will contain general information and particulars relating to over 1,250 electrical undertakings, including, where possible, copy of latest accounts and comparative tables showing progress. The manual is divided into six sections—viz, (1) telegraph, (2) telephone, (3) supply. (4) traction, (5) manufacturing, and (6) miscellaneous. In addition there is a directory of over 4,000 names and addresses of chairmen, directors, managers, secretaries, engineers, solicitors, bankers, and auditors of the undertakings given in the manual. The following are issued as supplements to the manual: (1) coloured diagram showing comparative results of 118 electricity supply undertakings; (2) analysis of the revenue accounts of electricity supply undertakings, showing the details of working expenses, revenue, profit or loss before providing for depreciation, reserve, debenture and other interest, which are stated separately, year of working, and number of units sold; (3) map of the electrical railways in London authorised and constructed. The price is 12s. 6d. net, and the work can be obtained from the publishing offices, Donington House, Norfolk-street, Strand, W.C., or from the offices of the *Electrical Engineer*, 139 140, Salisbury-court, Fleet-street, E.C.

Catalogues.—We have received from the Morley Engineering Company, Limited, of Leeds, a copy of their price-list of dynamos and motors. The list is very neatly and concisely drawn up, and contains information respecting 14 different dynamos and motors of the Morley D.B. type.—We have also received from the Campbell Gas Engine Company, Limited, of Halifax, a copy of their new catalogue and price-list of gas-engines. In this list considerable alterations have been made, both in the powers of the engines and in the prices, and the company state that they have entirely revised the whole of their gas-engine designs and patterns. The list is well illustrated and contains information concerning a large number of the gas-engines manufactured by the Campbell Gas Engine Company. A supplementary list is also given of horizontal engines, and horizontal engines specially adapted for electric lighting work.—We have received from the British Thomson-Houston Company, Limited, pamphlets Nos. 75 and 76. The former deals with electrically-operated cranes, and illustrates these cranes at use in various towns and for various purposes. At the end of the pamphlet the data required when ordering an electric crane is given. Pamphlet No. 76 deals with rheostats manufactured by the above company for generators and motors. The rheostats described are of three types—packed card, spiral wire, and iron grid—and they are made with a wide range of capacities. A number of drawings and illustrations of the rheostats are given in the pamphlet.—The British Westinghouse Company have just published their circular No. 1,032, which deals with their No. 56 tramway motor. A good description of this motor is given, sectional illustrations and diagrams being shown.

Digitized by Google

Blairgowrie.—On Monday a special meeting of the Blairgowrie Police Commission was held in the clerk's office to confer with Mr. Hawtayne, M.I.E.E., regarding the proposal to apply for a provisional order to give powers to light the burgh with electricity. Mr. Hawtayne was strongly of opinion that electricity could be supplied at half the price of gas. He was not impressed with the water power of the Ericht, and if the electricity were generated at Craigmill the size and length of cable necessary to carry it to the town would be so great that it would more than meet any gain to be derived from water power. He rather favoured the use of coal for generation by steam power at a centre in the burgh, and estimated that the cost of coal for lighting the burgh with electricity would be ½d. per unit. The Commissioners thought their best plan was to get the order in their own name, and afterwards transfer their powers to a company, as had been done in several places. If an order were granted to a company, the town could not take over the works for 42 years.

Paisley.—The burgh auditor, Mr. J. Balderston Whyte, has issued a report pointing out that while the electric works and installation were originally estimated to cost £33,750, they have cost £95,000, being £14,000 over the Council's powers. The buildings, originally estimated at £5,500, have cost £20,562. The machinery and plant, originally estimated at £18,200, have cost till date £33,277. As in the case of the buildings, when the estimates and contracts were accepted for the machinery and plant the amount was increased from the original sum to £28,573 and the excess expenditure in machinery and plant over the accepted estimates is thus only £4,704. For the high and low tension mains and distributors, also mains for arc lamps, the estimated original cost was £5,050, but this amount was increased when the estimates were accepted to £9,860, but the total cost now up till date is £20,725. A sum of £1 100 was estimated as the cost of transformers and sub-stations, which sum was subsequently increased to £2,548, whereas up till date the amount expended is £9,416, an increase of £6 868 over the accepted estimates. There was also an excess over the amounts estimated for arc lamps, pillars, etc. The report also shows that in 1896 the cost of the works and installation was originally estimated at £33,750 for 10,000 lights, or £65. 10s. per kilowatt. Taking the capital expended at £95,000, and the kilowatt capacity at 1,100, the cost of the installation was about £86 per kilowatt. With the extensions to mains, etc., required to take up the current still in reserve, the ultimate cost will probably be from £90 to £95 per kilowatt.

Taunton.—The following report of the Electric Lighting Committee was adopted on the 22nd inst.: "The British Electric Traction Company having applied to the Council to supply electric power for the company's proposed trams in the borough, your committee have ascertained that the company would be prepared to agree to the following terms: Terms of supply of electrical energy—for any quantity up to 60,000 units per annum, 2d. per unit; for any excess quantity up to 120,000 units per annum, 1½d. per unit; for any excess quantity from this figure up to 180,000 units per annum, 1½d. per unit. Guarantee by the company to take or pay for 60,000 units per annum, also that if the company cease to work within seven years they will pay one-half of the cost of laying down plant. Your committee present the following estimate of the cost of the plant which the Council would have to lay down for the purpose of supplying current to the company: 75-kw. direct-current generator, £600; 75 kw. direct current engine and generator, £1,200; alterations and additions to Willans engine, £200; 33-kw. motor-alternator, £370; switchboard and cables, £300; foundations and trenchings, £75; steam and exhaust piping, £175; contingencies, £150; engineers' fees, etc., £150—total, £3,220. Your committee recommend the Council to enter into the before-mentioned arrangement with the British Traction Company, and to authorise your committee—on the due execution of an agreement embodying the said terms—to obtain tenders for and proceed with the laying down of the said plant. Your committee recommend the Council to apply to the Local Government Board to sanction the raising by the Corporation of a loan of £3,220 to be expended on plant according to the above estimate."

Oban.—The following is the report by a committee appointed to consider and report on the question of introducing electric lighting within the borough, for which we are indebted to the *Oban Times*: "The committee, in accordance with the remit to them, visited Rothesay, Edinburgh, Leith, and Stirling, in which towns there are electric lighting installations in operation. At these places the committee had the privilege of meeting with the conveners or other representatives and the officials of the electric light departments of the corporations, and of being shown over the stations. The committee derived considerable profit and satisfaction from their visits, every opportunity being given them of making themselves generally acquainted with the working of the installations, and a great deal of valuable information being afforded them. The committee desire to put on record an acknowledgment of the great kindness shown to them by the representatives of the several burghs visited, and their thanks for the information so willingly given. The committee having given their best consideration to the matter remitted to them beg to report as follows—viz: (1) Public lighting.—At present Oban is poorly lighted, the illuminant being gas, and the cost thereof being 7s. 6d. per 1,000 cubic feet. The public lamps are 220 in number, and the total cost for lighting the burgh, including gas and wages for lighting and cleaning the lamps, amounts to £540 per annum. The committee believe that there is a general desire on the part of the community that Oban, as a tourist resort, should be much better lighted than it is at present, and the only satisfactory way to do so, in keeping with modern ideas, is by means of electric lighting. They desire to point out that in any such new scheme of lighting it is absolutely necessary to increase the amount of light in the principal thoroughfares, and that to do this, quite irrespective of the comparative cost of gas and electric light, would mean a somewhat increased charge for this purpose. The committee are of opinion that it would require at least 30 arc lamps, being about the number erected on Rothesay esplanade, to do this satisfactorily and with credit to the burgh. They found that the cost of lighting, etc., the arc lamps in the places visited was as follows: Edinburgh (where the installation has been a great success and the price is very low), £13 per lamp; Stirling, £17; Leith, £20; and Rothesay, £24; and they consider that a charge of not less than £20 per each arc lamp per annum, which would mean £600 per annum, would be necessary. From this, however, there would fall to be deducted the cost of the gas lamps rendered unnecessary, say 67 at an average cost of £2. 10s. 6d. each, being £170 per annum. (2) Private lighting.—If the foregoing suggestions were approved of, the committee are of opinion that electric lighting could be supplied to private consumers at the rate of 6d. per unit, which is reckoned to be equal to gas at 3s. 6d. per 1,000 cubic feet. The committee are also of opinion that a considerable supply of electrical energy could be sold for power, which would materially help to reduce the cost of private lighting. The committee accordingly recommend that application be made by the Commissioners of the burgh for power to introduce an electric lighting scheme within the burgh on the lines above set forth. The committee have further carefully considered the question of professional advice, and they have come to the conclusion that, to ensure success, it is necessary that an engineer of great experience should be consulted, and accordingly they recommend that application be made to Dr. A. B. Kennedy, London, who was engineer, amongst other schemes, for that of the Edinburgh installation, which has been from the start a very great success."

TRACTION.

Netherton.—The cars on the Dudley, Netherton, and Cradley Tramways have resumed running.

Berlin.—The electric railway from Saalburg to Homburg is to be continued as far as Frankfort-on-the-Maine.

Derby.—The last horse car route has now disappeared, and the first electric cars to West Derby were run on Sunday. They met with considerable patronage.

Smethwick.—The Town Council are about to promote a Bill with regard to the purchase of the tramways and for effecting public improvements in the borough.

Automobile Race.—The Automobile Club de France have agreed to a proposal to organise a Paris to Berlin race next year. The Kaiser intends to give £2 000 in prizes.

Llandudno.—The Urban District Council have appointed a committee to consider the advisability of constructing an electric tramway around the Great Orme's Head.

Littleborough.—The District Council have decided to apply in the next session of Parliament for a provisional order authorising them to take over and work the tramways at the expiration of the tramway company's lease.

Overcrowding.—The Imperial Tramway Company were recently fined 20s. and costs for overcrowding their tramcars during the Stockton race days. The defence was that the officials were unable to prevent the crowds overloading the cars.

Lowestoft.—The National Electric Traction Company have agreed to the proposals of the Council. A letter referring to the suggested leasing to them of the tramway and the suggested new agreement with the company has been referred to the Joint General Purposes Committee and the Legal and Parliamentary Committee.

City and South London Railway Co.—We learn that in consequence of the illness of one of the leading counsel in the case, the arbitration between the Ecclesiastical Commissioners, the rector and churchwardens of St. Mary Woolnoth Church, and the City and South London Railway, which was to have commenced to day, has been postponed for the present.

Ipswich.—The Joint Committee of the Corporation and the Dock Commission have recommended the latter to proceed with the works for which it has power for improving the tramway accommodation around the dock. The Joint Committee propose to continue its deliberations, and to formulate at no distant time a scheme for the further development of the port.

Kingswinford.—Colonel Von Donop and Mr. Trotter are about to inspect the electric tramway, which diverges from the Dudley and Stourbridge tramway at Holly Hall, runs to Kingswinford, and then, turning south, runs through Wordsley to Brettell-lane, where it connects again with the Dudley and Stourbridge line. Trial trips of the cars took place a few weeks ago.

Bradford.—A trial trip was made on the 23rd inst. on the new electric tramway between Thornbury and Stanningley, which has been constructed by the Bradford Corporation. The committee hope to have a regular service of cars running in two or three weeks. The cause of the delay is the want of a depôt at Thornbury, where a huge shed is to be erected capable of holding 100 cars.

Manchester.—At the meeting of the Tramways Committee on the 23rd inst. it was reported that the Board of Trade have intimated their approval of the proposal to lay a double line of tramways in Corporation-street. It was also stated that there are now nearly 500 men engaged on the work of relaying the permanent way. Progress is being made at the rate of about a mile a week.

Digitized by Google

Protection Guards.—A protection guard for tramway cars is just being tested in connection with the new electric tramways at Dundee. The guard, which was invented by Mr. J. Dewar, Dundee, differs from the guard commonly in use in respect that it is movable. A wooden bar stretches along the front of the car, and on its being struck the guard falls down close to the ground and the body rolls on to it. The tests are, according to the *Scotsman*, considered very successful.

Maidstone.—The Corporation have decided to promote a Bill for the following purposes: to authorise the Corporation (1) to construct and work tramways along certain streets and roads; (2) to widen certain streets and roads along which the tramways will pass; (3) to supply electrical fittings, to alter the date for making up the electrical accounts, and to make further provision in regard to the electric lighting undertaking, etc.

London County Council.—At Tuesday's meeting the Parliamentary Committee recommended that they should be instructed to renew in the next session of Parliament applications for powers (1) to reconstruct as a double line for electrical traction the existing single tramway line from Camberwell green to Vauxhall as mentioned in the Council's resolutions of July 25 and Oct. 17 1899. The proposed route along the Embankment has been abandoned.

Dundee.—The electric cars have been started on the Lochee-road. Eight cars are available, by which a 7½ minutes' service, beginning at 7 30 a.m., will be maintained, while the steam cars will be employed before that hour for the workmen's service. The Town Council have decided upon the promotion of a Parliamentary Bill for two tramway extensions—one a new line from the centre of the city to the north end *v d* a steep incline on the west of the Royal Infirmary buildings, and the other a new line at the east end. The estimated cost is considerably over £30,000.

Rowley Regis.—At the last meeting of the District Council it was stated that the Midland Electric Corporation for Power Distribution had given notice of works to be undertaken in Tipton-road, Tividale, thence past the Hange Colliery through city, Turner's-hill, Gadd's-green, Tippity-green Dudley-road, Dog-lane, Cox's-lane, Reddall Hill road, Spinner's End, High-street, Crad'ey Heath, Lomey Town, to the Quarry Bank boundary, Hales-owen-road. The committee have requested the clerk to examine the company's provisional order and inform them what (if any) powers the Council had for buying the works and supplying electricity themselves.

Kingston.—At the meeting of the Town Council on Tuesday, the Tramways Special Committee presented a report embodying some correspondence with the London United Tramways, Limited, a report from the tramways expert, Mr. J. Edward Waller, and a letter from the parliamentary agents, Messrs. Rees and Frere. The committee recommended that the Bill to be promoted in the next session should include, besides certain specified routes, all in the borough, one from the borough boundary in Maple-road to the Surbiton Station, in the Surbiton Council's district; another extending a short distance from the boundary on Kingston-hill into Coombe; and a third across Kingston Bridge to High-street, Hampton Wick.

Electric Street Car Manufacturing Syndicate.—At an extraordinary general meeting on Thursday a resolution was adopted ratifying an agreement made between the Company of the one part and the Electric Tramway Maintenance and Construction Company, Limited, of the other part, for the sale of the Company's business. This business was established about three years ago for the manufacture of motorcars, electric tramcars, and tramway appliances. It is reported that the Tramway Maintenance Company, who are a London syndicate, will buy 20 acres of land at Wednesfield for the purpose of extending the works. Mr. Thomas Parker, who was chairman of the Electric Street Car Syndicate, will join the Electric Tramway Maintenance Company.

Burnley.—Notices have been served upon the tramway company requiring them to sell their undertaking to the adjacent local authorities, and also upon the Corporation of Nelson, the Urban District Councils of Brierfield and Padiham, and the Reedley Hallows Parish Council, requiring them to state within three months whether they intended to construct the new lines within their own district or allow the Corporation to do the work. A very satisfactory report has been received from Major Cardew upon the plans and specifications for the reconstruction of the tramways prepared by the borough surveyor and the borough electrical engineer, and arrangements will be made for Major Cardew to inspect the line and meet the Tramways Committee at an early date.

Taunton.—At a special meeting of the Town Council on the 22nd inst. the Streets and Highways and Electric Lighting Joint Committees reported that they had received a communication from the British Electric Traction Company intimating that that company had arranged to take over from the local company the Taunton Tramways Order, 1900, and to at once start the work of laying the tramways if the Council would consent to the company (1) abandoning the proposed tramway in St. James's-street and substituting a line up Grays road and along Blake-street, as an approach to the company's proposed depôt; (2) substituting tar macadam for wood block between the rails. The committees duly considered the proposed variations in consultation with the company's engineer, and with a view to the Council adopting other proposals they recommended the Council to rescind the resolution passed at a meeting of the Council held Feb. 13, 1900, so far as it required wood blocks or paving to be laid by the tramways company between and on either side of their tramrails in the streets of the borough authorised by the tramways provisional order. The committee also recommended the Council to consent to the company's first request for the abandonment of the tramway in St. James's street and the substitution of a line up Grays road and Blake street. As to the second request of the company, they recommended the Council to require a single line of setts (dog-toothed) to be laid on either side of the metals or rails of the tramways, and to require the space between the metals to be made up with macadam, except opposite and for a sufficient distance on either side of the hospital, where wood blocks should be used. A long and animated discussion took place, and the committee's recommendations were eventually agreed to by a majority of 17 to 3.

Maryport.—The representatives of the Council appointed to attend conferences at Carlisle and Workington respecting the proposal to construct an electric tramway starting at Cleator Moor and passing through Whitehaven and Workington to Maryport, have made a report on the suggestions as to alterations of the route which were made and which are still being considered. The probable cost is put at £2,000 to £2,500 per mile where waste or spare land is available on the roadside, up to £6,000 per mile in other place, and in towns, including equipment, £10,000 to £12,000. The conditions named by the promoters are as follows: (*a*) The scheme to be carried out by a company, the company to have the tramways for 50 years, then the authorities to be compelled to buy on the following terms: the original cost to the company of the undertaking and all additions, with interest at the rate of 5 per cent. per annum on the share capital of the company to be guaranteed by the authorities. All the profits above and over the profit of 5 per cent. during the 50 years to belong to the company. Or, in the alternative (*b*) the option at the end of 21 years of purchase on the basis of a going concern price—*i.e.*, taking into consideration the past and prospective earnings of the company, with other details, and in addition 10 per cent. on the price so arrived at for compulsory sale. The promoters will not undertake to go on unless they are able to guarantee those who find money the full amount invested, with 5 per cent. interest for 50 years. Further consideration led the promoters to say that possibly the compulsory purchase at the end of 50 years might be changed to an optional purchase then or subsequently at agreed periods. At the second conference, when representatives of Workington, Whitehaven, and Maryport authorities were present, it was unanimously agreed that the terms proposed were not such as could be recommended for acceptance.

Bournemouth.—The County Borough Council have adopted the following report of the Tramways Committee: "Tramways extension.—The borough engineer reported that it would be advisable to construct a tramway from the proposed depôt in Southcote-road along Church-road and Palmerston-road, for the better working of the traffic, and that it would be necessary for this purpose to take powers to widen Church-road. Generating station and tramways extension.—The town clerk reported (verbally) that he was advised that it would be necessary to promote a Bill to obtain compulsory powers to purchase the freehold reversion of the Cumberland Estate in Southcote-road, also to obtain powers to construct tramways outside the borough. Recommended that the Council promote a Bill in the next session of Parliament for, amongst other things (*a*) obtaining compulsory powers for the purchase of the Cumberland Estate; (*b*) the purchase of the lands necessary for street widening; (*c*) the construction of the tramways extensions already resolved upon by the Council, including the extension and widening mentioned in Clause 1 of the report; and (*d*) for power to use the Southcote-road depôt as a generating station. Winton.—A letter (dated Sept. 21) from Mr. T. E. Gosling, clerk to the Urban District Council of Winton, was read, stating that his Council would consent to the proposals of the Corporation, provided the line of tramways were extended to the old boys' school at Moordown Scheme (General).—Loan (342-2): A letter (dated Oct. 1) from the secretary of the Board of Trade was read, stating that the Board would hold a local enquiry on the subject of the Council's application, and asking for particulars as to the debt, etc. The town clerk reported (verbally) that these had been forwarded. Alteration of Tramways.—A letter (dated Oct. 4) from the secretary of the Board of Trade was read, stating that the Board saw no objection to the proposed doubling of certain tramways authorised as single lines by the order, providing that no rail should be laid in connection with these alterations within 9ft. 6in. of the edge of the footpath, except in accordance with Section 13 of the order."

Sheffield.—The tramways department of the Corporation continues to push on its work effectively. The next district to be provided with cars will be Heeley, which is practically ready. We quote the following interesting particulars from the *Sheffield Daily Telegraph*: "The old difficulty of want of power still faces the department, but not nearly so acutely as in the past. The energies of the 500-kw. engine started this year are now almost absorbed by the demands of the various sections, and there is very little spare power available in the case of a breakdown. However, the second 500-kw. engine, which is capable of driving 50 cars, is rapidly nearing completion, and there is every hope that it will be ready for work by Nov. 10, the date given to the contractor. The first section to feel the benefit of its running will be Brightside. The equipment of this route is practically completed. Only a few odds and ends of things require finishing off, and the section will be ready for the cars as soon as power can be obtained, or very soon after. Walkley also requires attention. An early step will be the placing of three double-deck cars on this route to run as far as Harcourt-road. The cables are being laid now. The deliveries of cars have

Digitized by Google

been very good lately, and, in addition to the 65 now running, there are upwards of 30 in reserve at Tinsley and Queen's-road. Besides which, the Corporation carmaker's hammer rings merrily at the Nether Edge workshop, where the framework of the first of six cars has been laid down. There need be no fear of deficiency in this respect for some time to come. The laying of the lines on the Darnall and Crookes sections has made capital progress, and the fixing of the poles, which has now been started, will go on as rapidly as possible. On the Owlerton route, too, work is being pressed forward very rapidly. Another six months, and great things will have been accomplished. Kelham Island must always be remembered. Engines and boilers must be provided, or the extension of lines will be of little use. And so the committee is not stopping short at the new 500 kw. set. The present building is still large enough to accommodate two sets each of 1,000 kw. power, and the specifications for one of these have already gone out."

Hull.—At the last meeting of the Corporation Works Committee Mr. Barnard (electrical engineer) reported on the breakdowns in the electric tram service, and advised the committee to appoint a linesman, with a labourer, to examine the whole of the overhead wires every fortnight. The recommendation was adopted. At a meeting of the Corporation Works Committee held on the 19th inst. a recommendation of the Tramways Sub-Committee was adopted to request the town clerk to insert in the proposed Bill powers for extending the present tramways in Prince's-avenue along Queen's-road and Newland-avenue to Cottingham road. It was also resolved to insert powers to run the tramways from Whitefriarsgate Bridge, down the new street, and along Lowgate to the pier. The electrical engineer submitted a report as to what steps he would recommend should be taken to remedy any existing defects in the tramways equipment. With regard to the wear and tear on the car equipments (all types) he considered that it was necessary to provide for the complete overhauling of the cars one by one, and for that it would be necessary to set on an additional fitter and two labourers who would work on that alone. With regard to the breakages of the overhead lines, which he admitted had become much more frequent of late, he said that many of the breakages had been due to faulty workmanship, and had been repaired by the contractors at their own expense. Other cases were due to carelessness on the part of the Corporation employés, and still more were due to fair wear and tear. The two first causes were now giving rise to fewer breakages, and would probably soon cease, but the wear and tear of the line was, of course, steadily increasing. It should be remembered, in comparing the Hull system with other towns, that, owing to the quick service over short lines, the car miles run on any one piece of line were very heavy indeed, and the wear and tear was correspondingly great. During last year, with seven miles of track in use, the car miles run were approximately 15,100 per week, or each fixture on the overhead line had 2,157 trolleys running over it every week. The only way to avoid accidents from wear and tear, therefore, was to adopt a rigid system of inspection of the lines, every hanger and fitting being gone over at least once a fortnight. Messrs. Siemens Bros. and Co. had been doing that on their own behalf to a certain extent, but the electrical engineer considered it was now time that the Corporation undertook the work, and he suggested the employment of a competent linesman and labourer to maintain the trolley wires and mains, and that arrangements should be made to hire a horse and driver to take the tower wagon over the lines every Sunday morning. He did not consider that the Hull system could be called seriously defective, and the number of accidents from defects on the electrical equipment were certainly not more in proportion to the car miles run in Hull than in other towns. He had, therefore, rather suggested the means of avoiding accidents in the future than the remedying of defects. With regard to Messrs. Siemens's controllers and trolley heads, the firm had submitted new designs, which they undertook to fit on all their 15 cars. The report and the recommendations contained therein were adopted.

PROVISIONAL PATENTS, 1900.

OCTOBER 15.

18298. Improvements in electric couplings. Charles Bell Walker, 2, Ormonde-terrace, Regent's Park, London.

18337. Improvements in electrical fuses or cut-outs, and indicating carriers for same. William Henry Wood, 32, Warwick-road, Birmingham.

18345. Improvement in telegraphic codes. Adolphus Washington Greely, 19, Holborn-viaduct, London.

18347. Switch apparatus for electrically-propelled vehicles. Victor Isidore Feeny, 60, Queen Victoria-street, London. (Allgemeine Elektricitäts-Gesellschaft, Germany.) Complete specification.)

18357. Improvements in and in apparatus for taping insulated conductors. George Edward Heyl-Dia, 6, Lord-street, Liverpool.

18372. An operating device for the regulating mechanism of the electric ignition of explosion motors. Louis Schreiner and Gratien Elie Nicolas Michaux, 18, Buckingham-street, Strand, London.

18376. Improvements in or relating to trolley poles for electric traction and power purposes. Robert Price Strachan, 70, Chancery-lane, London.

OCTOBER 16.

18397. Improvements in the electrolytic decomposition of metallic salts and in the apparatus employed therefor. James Dick Gilmour, 115, St. Vincent-street, Glasgow.

18434. Improvements in or relating to the feeding mechanism of arc lamps. Charles Oliver, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

18451. Circuit controller for electric street railway cars and other uses. William Andrew McCallum, 322, High Holborn, London. (Complete specification.)

18471. Improvements in electric arc lamps. William Edward Pugsley, Henry Mitchell Descher, Violette Lucilda Douglas, and William John Robinson, 18, Buckingham-street, Strand, London. (Complete specification.)

OCTOBER 17.

18497 Improvements in coin-freed apparatus chiefly for telephone instruments. John Davis Miller, 62, St. Vincent-street, Glasgow.

18498. Improvements in automatic guards or protecters for electric or other tramway cars William Dewar, 41, Reform-street, Dundee.

18529. Improved electric heat generator. Louis Schramm, Heim-Ruh, Anerly-road, Westcliffe-on-Sea.

18534 Improvements relating to electrically-operated clocks. Hjalmar Emanuel Andersson, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

OCTOBER 18.

18557. Improvements in and connected with lightning arresters and high-voltage guards or heating coils for telephonic purposes. Hermann Oppenheimer, 55, Redcross-street, Barbican, London.

18613. Improvements in rectifiers for periodic electric currents The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Alexander D. Lunt, United States.) (Complete specification.)

18614. Improvements in end play devices for rotary electrical machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Henry Geisenhoner, United States.) (Complete specification.)

18615. Improvements in electromagnetic blow-outs or fuse boxes. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett, United States.) (Complete specification.)

18616. Improvements in electric controllers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Frank E. Case, United States.) (Complete specification.)

18617. Improvements in high-potential electric circuit breakers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett, United States.) (Complete specification.)

18618. Improvements in electrical indicating and measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Lewis T. Robinson, United States.) (Complete specification)

18642. Improvements in low-pressure incandescence lighting. Paul Greyson de Schodt, 322, High Holborn, London.

18645. Improvements in electric furnaces. Arthur Parker, 6, Bank-street, Manchester.

18649. Improvements in or connected with apparatus for making tubes of lead or the like, and for sheathing electric cables with lead or the like. Henry Edmunds, 47, Lincoln's-inn-fields, London.

18656. Improvements in commutator brush-holders. Harry Bishop, 53, Chancery-lane, London.

18658. A new or improved system of and apparatus for secret electric transmission. Pierre de Chimkévitch, 18, Buckingham-street, Strand, London.

OCTOBER 19.

18661. Improvements in wireless telegraphy. Sidney George Brown, 9, Putney hill, Putney, London.

18681 Improvements in electric fire-alarms. Henry Simpson and Robert Tomlinson, 34, Castle street, Liverpool.

18706. Improvements relating to electrically heated laundry irons and like appliances. Julius Hayem, 45, Southampton-buildings, Chancery-lane, London.

18707. Improvements relating to micro-telephonic apparatus. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (The Telephon-Fabrik Actiengellschafs, vorm. J. Berliner, Germany.)

18718. Improvements in magneto-electric ignition devices. Willy Seck, 111, Hatton-garden, London. (Complete specification.)

18729. Improvements in or connected with the generation of electricity. John George Lemon and George Pirie, 53, Chancery-lane, London.

OCTOBER 20.

18741. Improvements in those systems of electric tramways and railways in which current is collected from two insulated conductors (positive and negative), such improvements being in connection with crossings and turn-outs. John Johnston, 53, Bothwell-street, Glasgow.

Digitized by Google

18742. Improvements in electric lampholders. Christopher Thomas Briscoe, Penny Bank-chambers, Halifax.

18757. Improvements in safety devices for the trolley poles of electric cars. Charles Revill Bellamy, William John Turner, and Daniel Richard Wallwork Hardman, 34, Castle-street, Liverpool.

18762. Improvements in wireless telegraphy. Sidney George Brown, 9, Putney-hill, Putney, London.

18779. Improvements in electrical circuit-closers, particularly adapted for use with the indicators of railway signals. Charles Cheal and Henry John Millner, 55, Chancery-lane, London.

18789. Improvements in and relating to electricity meters. Friederich Ludwig Catenhusen, 27, Chancery-lane, London.

18793. Improvements in or relating to electric railways operated on the conduit system. William Chapman, Westinghouse-building, Norfolk-street, Strand, London.

18794. Improvements in insulators. William Chapman, Westinghouse-building, Norfolk-street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Nov. 10.

1899.

20493. Electrical signalling systems for railroads. Berry.

21650. Systems of control for electrically-propelled vehicles and trains. British Thomson-Houston Company, Limited. (Potter and Case.)

21655. Systems of controlling electric motors. British Thomson-Houston Company, Limited. (Garfield.)

21660. Electric circuit breakers. British Thomson-Houston Company, Limited. (Buck.)

21662. Electric arc lamps and magnets therefor. British Thomson-Houston Company, Limited. (Stevens.)

24594. Automatic electrical cut-outs. Greenstreet and Selby.

25746. Alternating-current electric meters. British Thomson-Houston Company, Limited. (Steinmetz.)

1900.

10273. Controller regulators for electric motors. Haddan. (Garton Daniels Company.)

10312. Wireless telegraphy. Wilson.

10312a. Electric wireless signalling. Wilson. (Date claimed under Patents Rule 19, June 5, 1900.)

10751. Electrical generators and electrical motors. Willatt.

12249. Thermo-electric cells. Lake. (Langville.)

12950. Apparatus for the electrolysis of water. Garuti and Pompili.

13415. Manufacture of electric insulators. Y. López.

NOTES.

Camera Club.—At an ordinary meeting of the Camera Club to be held this evening, Mr. Jas. Cadett will read a paper on "The Latest in X-Rays."

Smoking Concert.—A smoking concert in connection with the Faradian Club is, we learn, to take place on Friday evening, Nov. 9, at St. James's Restaurant. The Regent Saloon is to be used on the occasion, the concert commencing at 8 p.m.

Institution of Electrical Engineers.—We are informed that the twelfth annual dinner of the Institution of Electrical Engineers will be held in the grand hall of the Hotel Cecil on Monday, Dec. 2. The Commander-in-Chief, Lord Wolseley, is, we understand, among the guests who have already accepted.

Russian Telegraphs.—The postal telegraph system between Russia in Europe and Siberia have proved so deficient and unsatisfactory that steps have had to be taken with a view to the improvement of it. Thus the first telegraph wires were laid in July last, and skilled linesmen and telegraphists hurried to the spot. Great progress has, we learn, been made since July, and the way in which the operations are being conducted are being favourably commented upon in the quarters interested.

Extra Current. — The following abstract, which appears in the *Electrical World*, is of a paper contributed by Mr. Johnson to *L'Eclairage Electrique* on the subject of the extra current due to breaking a circuit which contains an induction coil, a cell, an interrupter, and a condenser in shunt with the interrupter. He supposes that the discharge of the condenser is oscillating, and calculates the maximum potential difference between the plates of the condenser. The formula found shows that this maximum potential difference is the smaller, the greater the capacity of the condenser. The greater the capacity, the smaller is the liability to sparking when the circuit is broken; this is in agreement with experiments. When a spark occurs, the phenomenon becomes very complicated.

"The Street Railway Review."—The *Street Railway Review* for Oct. 15 is a special number, which commemorates the holding of the nineteenth annual meeting of the American Street Railway Association and the fourth convention of the Street Railway Accountants' Association of America. In this number a history of the rise of Kansas City, in which the convention was held, is given, after which comes a history of the street railway system of Kansas City. With respect to this latter article, a large number of illustrations are given showing the track in course of construction, views in the power stations, cars car-sheds, etc. Information is also given in this number concerning the Kansas electric light undertaking, and also of the various local men connected with the convention.

Electricity on the Congo.—What promises to be the first electricity station in the Congo district is, we learn, soon to be started at the Roman Catholic Mission of Luluabourg, which is situated on the River Lubia, a tributary of the Kaosas River, which is itself a tributary of the Congo. The head of the mission, Father Gambier, who has for several years been in Luluabourg, is now proceeding there again, taking with him a dynamo, turbine, lamps, cables, wires, etc. He proposes to obtain the necessary power from a waterfall, the fall being some 28ft. high. The dynamo will light 150 lamps, and it is proposed to instal 100 incandescent lamps and three arc lamps. The dynamo was manufactured by a firm in Charleroi, and the turbine is of French construction. We hope, however, to hear further of this pioneering effort in the Belgian Congo district, and trust that when fitted the installation will work successfully.

Institution of Electrical Engineers (Glasgow Section).—The opening meeting of the Glasgow section of the Institution of Electrical Engineers is, as we announced in our last issue, to take place on Nov. 14. On that occasion a paper on "Electrical Supply" is to be read by Mr. W. A. Chamen, the Corporation electrical engineer of Glasgow, and a paper written by such an authority should be well worth hearing and considering. We are glad to learn that sufficient papers have been promised already for this section to provide important and interesting discussions for the whole of the session. Mr. E. G. Tidd, the hon. secretary, also announces that any member wishing to take part in any discussion can, a short time previously, obtain advance copies of the papers by applying to him at 25, Gordon-street, Glasgow.

American Electrical Exports.—The Treasury Department, in recently issued returns, gives some figures relating to the exports of electrical machinery and apparatus from the United States during the first eight months of the present year. For this period the exports of electrical machinery reached the sum of about £718,000, as against a value of £305,600 for the corresponding period of last year. The value of the exports of instruments and apparatus for scientific purposes, including telegraph, telephone, and other electrical apparatus, increased from £722,000 during the eight months of 1899 to £834,000 for the corresponding period of 1900. In speaking of these figures, the *Western Electrician* warns electrical manufacturers against over-production, and thinks that foreign markets should be assiduously cultivated in order to provide an outlet for the large amount of electrical machinery, etc, manufactured in America.

Liverpool Tramways. — A serious breakdown occurred on Monday last on the Liverpool electric tramway system, when the cars running in some of the most important streets in Liverpool had to stop running. The accident which caused the suspension of service was the breaking of a span wire on the Pierhead route. The span which collapsed was fixed to the Pierhead buildings, and the result of it breaking was that two trolley lines fell, thus completely blocking the whole system, but fortunately no injury was occasioned either to individuals or to the cars. One explanation which is given as to the cause of the occurrence was that a trolley on one of the cars came off the wire and struck the span, but this the conductor concerned denies, he stating that the breaking of the span threw his trolley off the wire. Mr. Bellamy's staff were kept hard at work trying to replace the wires, and about an hour after the accident, which happened at a quarter past three, managed to restart the service.

Electrical Treatment of Rheumatism (?)—Sir Jas. Grant, M.D., of Ottawa, has, says the *Electrical World*, for some time been making experiments as to the treatment of human ailments by means of electricity. Thus for many years he has been in the habit of treating cases of supposed muscular rheumatism by the insertion of small steel needles, the number varying according to the area affected. The needles remain stuck in the muscles for one or two minutes, and the previous hard, tense condition, approximating one of tetany, relaxes, and the patient is able at once to use the muscles. Experiments point to an abnormal storage of electricity in the tissues. It may be stored as a result of sudden draughts and cold. When the inserted steel needles are touched, the electrical

Digitized by Google

accumulation is discharged, passing through the body of the operator without any serious result. There is almost immediate relief in lumbago from this acu-puncture. While the treatment may give relief, we are not believers in Sir J. Grant's explanation that it is due to electrical phenomena.

Novel Drying Lines.—Mr. G. A. Wiese, who has recently returned from China, to which country he went to instal the electric light in the city of Canton, gives in *Electricity* of New York some of his experiences with the inhabitants of the Flowery Land. Thus he states that in many places the streets of Canton were too narrow for poles. For this reason he had to get permission of the authorities to cut holes in the walls of the buildings, and into these holes modern cross-arms were inserted. After the cross-arms had been placed and the wires strung a tour of inspection was made, and the inspectors were astonished to find that the wires were loaded with laundry work that had been hung out to dry. A current of 1,000 volts was running through the wires at the time, but luckily no one had been killed. When the Chinese were warned of their danger they only laughed, and said that the electricity dried their clothes much quicker than the sun, so they refused to move their wash. Mr. Wiese finally had to report the matter to the authorities, who detailed a guard of 40 soldiers to go with him and put an end to the clothes-drying.

Platinum-Silicium Resistances.—A short article in the *Elektrotechnische Zeitschrift* by Mr. Victor Rodt describes some experiments conducted with a view to ascertaining the chemical resisting qualities of platinum-silicium resistances. Resistances consisting of a thin film of the alloy fused on to porcelain rods have been recently introduced by a German firm, we are told. The rods have a length of 2·83in. to 4·75in., and a diameter of about 0·2in. Although originally intended for use in connection with electrical heating apparatus, it is concluded by the writer that these resistances are also eminently adapted for work where chemical action has to be guarded against. However, the suitability of the resistances for making accurate measurements has not yet been determined, nor do the methods hitherto employed of connecting the platinum-silicium with the conductor exclude the possibility of slight fluctuations of the current density. On the other hand, the resistance offered against overloading, not to mention chemical and thermal influences, confers upon this form of resistance such advantages for certain classes of work that its use deserves consideration.

The Cable-Ship "Orizaba."—We noted recently that the Pacific Coast Steamship Company's vessel "Orizaba" was wrecked on Rock Point Reef, St. Michael's Island, on Sept. 20, while engaged in laying a cable across the Behring Sea. At the time it was thought that the vessel could be saved, but it is now reported that she is a total loss. The captain lays all the blame upon the United States Hydrographic Bureau, stating that the wreck was due to three large uncharted rocks in a place in which the charts showed 36ft. of water. On finding it impossible to get the ship off the rocks, efforts were directed to getting out the cable, and this was accomplished on Sept. 23, the cable being quite uninjured. Mr. G. F. Porter, who was with the expedition and in charge of the kerite cable, hoped to have laid the entire cable by the middle of October and before the Sound freezes. The undertaking is attended with great danger on account of the swiftness with which the ice moves, great bergs appearing without warning in such numbers as to make it impossible for a ship so trapped to escape, and once caught in the floes or heavy drift ice the unfortunate vessel, if not crushed like an eggshell, would be compelled to remain a prisoner all winter. It may be possible to run only the shorter cable, but it was thought at the cable office that Mr. Porter would probably succeed in laying both lines.

A Distortionless Commutator.—The General Electric Company of America has taken out a patent for a commutator which will be free from distortion under centrifugal and other strains, thus tending to keep the bars of the commutator in perfect alignment during the entire service of the machine. The device consists in locking the several bars of the commutator together, so that no one of them can slip with relation to the others, by means of a key passing through the several bars, but insulated therefrom. The key is formed sectional, each segment supporting and locking a number of contiguous commutator segments. A keyway is preferably provided at or near the middle of the length of the bar, so as to bind the latter down against the supporting drum for the commutator bars. In assembling the commutator, the keys, with their segments, are set successively in place and fastened by bolts on the inside of the cylindrical support. The keys are carefully insulated from the commutator segments by a lining of mica on the inner walls of the keyway. The last segment inserted after the balance of the commutator has been assembled, may be insulated by strips of mica or similar material fastened over the end walls of the key segment, and its commutator segments and the combined parts slipped into place and bolted fast, after the fashion of the balance of the segments.

Connecting Alternators in Parallel.—Mr. Perot recently read before the French Academie des Sciences a paper concerning the connecting of alternators in parallel. The paper is abstracted in the *Electrical World* digest as follows: "The author first considers two alternators connected in parallel, which have E.M.F.'s with identical fundamental waves and identical higher harmonics, the only difference being that the wave of one alternator has a special higher harmonic which is missed in the wave of the other alternator; he calculates the current which is due to this special higher harmonic, and the E.M.F. at the terminals of the two alternators. This is proportional to the ratio of self-induction of the alternator, which has not that special higher harmonics and the sum of the self-inductions of both alternators. He then deduces the results for more than two alternators in parallel. He considers an alternator, the wave of which has higher harmonics, and supplies current to a synchronous motor of small power and of small self-induction compared with that of the alternator; the motor may be supposed to be normally excited and unloaded; it behaves like a machine with a sine wave coupled to the alternator, so that the formula mentioned above can be applied; it follows that the E.M.F. at the terminals of the alternator, due to the higher harmonics of the alternator, is decreased in the ratio of the self-induction of the motor to the sum of the self-inductions of motor and alternator, which ratio was supposed to be very small, in other words, the E.M.F. at the terminals of the alternator becomes nearly a pure sine wave.

St. Pancras Vestry.—We have received from Mr. C. H. T. Barrett, the clerk to the St. Pancras Vestry, an interesting retrospect of the work done by the Vestry of St. Pancras by its predecessors for the period extending from 1718 to the present year. The retrospect in question was prepared by Mr. E. A. Brown, of the Burials Department of the Vestry, from the information in the books and records in the Vestry's strong-room. To any one interested in the various methods of local government

Digitized by Google

which have been tried during the past two centuries in London areas, this retrospect will be most valuable. We gather that the open vestries, which were established in the early part of the eighteenth century, used to hold their meetings in alehouses, and conducted their business more in the interests of the large landowners than of the ordinary inhabitants. The open vestry was followed by what was known as the select vestry, which was a self-electing body, and hence could in no way claim to represent the various people whose interest it ought to have served. The Select Vestry of St. Pancras held its first meeting in June, 1819, and it was not until 1832 that the ratepayers had any part in electing their representatives. It was in 1853 that the present Vestry commenced to meet, and it has a long list of improvements to its credit. The author, however, expresses the opinion that the Vestry meets too often and talks too much, and that personalities are introduced more than need be. With this conclusion most people will agree, and we trust that the reduction of the number of representatives on the new borough councils will tend towards more businesslike procedure.

Institution of Junior Engineers.—The annual general meeting of this institution was held on Saturday last at the Westminster Palace Hotel, the retiring chairman (Mr. Basil H. Joy) presiding. There was a large attendance of the members. After the usual business, the council's report on the work of the past year was presented and adopted. It stated the net increase in membership had been 30, the membership roll now numbering nearly 600. M. Gustave Canet, of Paris, and Prof. W. E. Dalby, of London, had been elected honorary members. The institution premium for the best paper read by members during the session had been awarded to Mr. E. W. Porter, A.M.I.C.E., for his paper on "A Comparison of Railway Bridge Structures of Moderate Dimensions, and of Methods of Determining their Working Loads." Seven meetings had been held and eleven visits paid to works, apart from the visits arranged in connection with the summer meeting at Newcastle-upon-Tyne and Sunderland. Reference was also made to the fifteenth anniversary dinner and to the conversazione. The institution had been represented at the receptions given last June by the Socié é des Ingenieurs Civils de France in connection with the Paris Exhibition. The scrutineers reported the election of the following officers and members of council: chairman, Mr. Percival Marshall; vice-chairman, Mr. Ernest King; hon. librarian, Mr. Lewis Rugg; hon. auditors, Messrs. Adam Hunter and A. W. Marshall; and secretary, Mr. W. T. Dunn. The members of council were Messrs. Louis F. Awde, W. Rushworth Beckton, H. Norman Gray, and W. G. Wernham. A vote of thanks was accorded the retiring officers and council, and was acknowledged by Mr. Joy, who inducted his successor into the chair.

A New Battery Switch.—Some of our German contemporaries describe a new type of accumulator switch which is designed to avoid the necessity of employing a booster to furnish the extra voltage for charging when the charging dynamo is required to provide current at the normal voltage for other purposes at the same time. The new switch effects this end by enabling two-thirds of the total number of cells contained in the battery to be always charged together. It is pointed out that for a battery having a capacity of 100 amperes at 110 volts terminal pressure, 60 elements are necessary. The mean charging pressure required per element is 2·4 volts. When charging the battery in parallel halves, there are 30 elements in each half, for the charging of which $2{\cdot}4 \times 30 = 72$ volts mean charging pressure is necessary. But since the line pressure is 110 volts, $110 - 72 = 38$ volts, with a current of 100 amperes per half—that is to say, a total of $2 \times 100 \times 38 = 7{,}600$ watts, or about 11·7 h.p. must be choked back by means of resistances. The driving engine is called upon to furnish about 34 h.p. for the charging process alone. If, on the other hand, we charge two-thirds of the total number of cells—that is to say, 40 elements, which require $40 \times 2{\cdot}4 = 96$ volts—there will be only $110 - 96 = 14$ volts to choke by means of resistances, which with 100 amperes represents about 22 h.p., while the driving engine is called upon for only 17 h.p. Extensive application of this method of charging has been prevented hitherto by the absence of a switch which would enable the individual thirds of the battery to be switched together as desired without the possibility of error. But this difficulty is claimed to have been satisfactorily overcome by the new switch introduced by the well-known Berlin company associated with Dr. Paul Meyer.

Wind Power.—The utilisation of wind power for the generation of electricity continues to receive attention in Germany, and we learn from the *Elektrotechnische Zeitschrift* that Mr. Gustave Couz, of the Gustave Couz Elektricitäts Gesellschaft, in Hamburg, has been experimenting in this direction with promising results. A wind motor has been erected at the works of the company in question, which has a diameter of 40ft. and an effective sail surface of 1,070 square feet. The motor works at the rate of about 11 revolutions per minute, which speed is regulated by the automatic modification of the direction of the sails to the wind. With this motor an output of 1 h p. to 30 h.p. and more may be obtained, according to the force of the wind, which power is transmitted to a 30-h.p. shunt-wound iron-clad dynamo, designed to give 120 amperes at 160 volts terminal pressure when running at 700 revolutions per minute. The current generated by this machine is conducted to a switchboard and thence to a battery of accumulators having a capacity of 66,000 watt-hours, or may be delivered to electromotors. So soon as the wind has attained a velocity of 8ft. per second, the dynamo may be brought up to its full terminal pressure. With an increasing wind force the charging of the battery may be commenced. Automatic cut-outs for the dynamo were proved unnecessary with the arrangement adopted. The electromagnets of the dynamo are permanently excited by the battery, the + pole being connected with the battery, while the − pole is connected to the charging switch. By this arrangement automatic regulation of the dynamo voltage is secured. An automatic battery-discharging switch serves to maintain the line tension of 110 volts constant, both during the charging process and when discharging. Small motors are connected up to the lighting circuits, but larger ones are supplied by separate circuits branched off from the terminals of the generator.

Electricity on the Metropolitan and District Railways.—The announcement that the two companies controlling the most of the underground lines in London have invited tenders for the complete conversion of these lines to electric working is good, and also the statement that the offers from the selected firms must be in by Dec. 1. As is known, there are absolutely no engineering difficulties of any moment to be overcome in the conversion of these lines, and we do not doubt that any one of those firms selected will be able to carry out the change in such a way as to give an enormous saving of the running expenses. There would also be an increase in the traffic returns owing to the higher speed and greater convenience and comfort, which would be most acceptable to the companies. Behind all this, however, there is the unpleasant

Digitized by Google

fact that the board of directors must have additional capital, and that this new capital can hardly be provided unless reasonable returns on it can be guaranteed. For instance, one company has not paid any dividends on its ordinary stock for years, and the stock in question stands at a very low figure in consequence. It is not, therefore, to be expected that the new capital to be found will rank with this old stock. We have heard rumours that the difficulty is to be got over by leasing the undertaking to a new company, which would provide the cost of conversion. According to the *Daily Mail*, Mr. Alexander Siemens offered the companies terms somwhat similar to these 10 years ago. In his offer, however, the company would not have gained much beyond the increase in the traffic returns, as the running charges calculated out per train mile were to have been paid to the electrical contractors providing the electrical equipment. In other words, the cost per train mile would have been the same, but the revenue would have increased. More definite news as to the proposals of the contractors will be awaited with interest, and we trust that there will not be any great delay in deciding on the acceptance of the tenders to be submitted in December. We note by the way that Mr. T. Parker, of Wolverhampton, has been added to the list of consulting engineers advising on the question of the conversion.

German Enterprise.—Through their London house—*i.e.*, the Electrical Company, Limited—we have received from the Allgemeine Elektricitäts-Gesellschaft, of Berlin, two interesting pamphlets. One of these describes in German the firm's exhibits at the Paris Exhibition, and, besides some instructive matter relating to the Nernst lamp and other special attractions to be found in the A. E. G. pavilion, contains some beautifully-executed illustrations. We have already on previous occasions remarked upon the high artistic merit characterising the catalogues issued by this enterprising firm; the samples now under notice certainly betray no retrogression in this respect. In fact, we again have to acknowledge super-excellence of design and execution. But as the exhibits of the company at Paris have been fully dealt with in our columns, we will pass on to the second catalogue, which contains many excellent illustrations of the firm's works and productions, not to mention some interesting data relative to the continued growth of their immense business. Incidentally we learn that the capital invested in the parent and affiliated companies amounts to the enormous sum of £15,000,000. The share capital fully paid up in the parent company is now £3,000,000. From 1890 to 1894 the share capital stood at a round million, but has since undergone a rapid increase, notwithstanding which the dividend-earning capacity of the concern has been more than maintained, a steady 15 per cent. per annum having been paid since 1896. Upwards of 14,000 workpeople are employed at the company's Berlin works, which cover an area of 57 acres. For the year 1898 9 the output in dynamos and motors from these works totalled 12,000, representing an aggregate capacity of 163,000,000 watts. The separate system of driving by means of three-phase motors is in vogue at the works. The various departments, each huge in itself, are illustrated in the catalogue. In the incandescent lamp department a yearly output of 10,000,000 lamps has been reached, which is equal, we are told, to one-half the annual consumption in all Europe. The productions of the works may be said to include practically every article required in the electrical industry, but it is quite beyond the scope of a note to give data relative to all, so we must refer the reader to the pamphlet itself for further information.

The Hunting in Rotary Converters.—Mr. C. P. Steinmetz continues his interesting articles in the *Electrical Review* of New York on "The Systems and Apparatus for Light and Power Distribution." Amongst the points taken up in the last article which we have read in the series is that of the hunting which occurs in the rotary converters for changing alternating current into direct current. Mr. Steinmetz points out that to understand the phenomenon of hunting it is well to take the simplest case, of a generator of absolutely steady and constant E.M F. feeding a converter or synchronous motor over a circuit of certain resistance and self-induction or reactance, with a constant load on the converter. The usual theory of the text-books then shows that the counter E.M.F. of the converter adjusts itself to a definite phase relation with regard to the generator E M.F., depending upon the load and the excitation. Closer investigation shows, however, that the phase of the counter E M.F. of the converter, and thus its speed, and in consequence thereof the current, can pulsate around a mean position, and the power supplied by the generator pulsates correspondingly with a period depending upon the E.M.F.'s, the impedance, the momentum of the moving masses, and several other constants, but usually of a magnitude of somewhere near one cycle per second. During the time of acceleration the generator supplies an excess of power, which is stored by the moving masses and returned during retardation, where the generator supplies less power than the load on the converter represents. This period is entirely definite and independent of wave shape or engine pulsation, although the latter may start the oscillation. He continues by stating that several of the constants upon which hunting depends are beyond the control of the designer of electrical machinery, and consequently it is well to prevent hunting by using damping devices to prevent the surgings which occur. The oscillation of the armature reactions which cause a considerable amount of the hunting can best be prevented by using low-resistance closed circuits of copper in and around the field poles. Another point taken up in this article is the fact that in the design of engines for driving alternate-current machinery for the transmission of energy, the uniformity of speed is not so important as even turning moment. In fact, in order to get the load properly distributed between a number of steam-driven sets, an appreciable fall of speed between no load and full load is advantageous. It is most essential, however, that there should be no hunting from the governors, and Mr. Steinmetz points out that a heavy flywheel does not prevent hunting, but rather takes the opposite direction, and tends to increase it.

The Commercial Value of Electromobiles.—In articles contributed by Mr. R. A Fliess to the *Electrical World*, the author deals with the electric automobile when used for commercial purposes, and gives a number of tests which he has carried out both in good and bad weather. From the fair-weather tests on level asphalte, he concludes that an ordinary light delivery wagon fitted with friction-reducing devices requires about 90 watt-hours per ton-mile. Without such friction-reducing mechanism 95 watt-hours per ton-mile were needed. The vehicles required about the same watt-hours per ton-mile whether loaded or empty. Tests made with pneumatic tyres and solid tyres showed that vehicles fitted with pneumatic tyres indicated a slightly increased rate of power consumption over those fitted with solid tyres. When travelling over a macadam road surface, the rate of power consumption was nearly 116 watt-hours per ton-mile. Tests were also made with a light electrical postal wagon under very adverse weather conditions. In this case tests were made just after a very severe snowstorm, the snow in some places being 4in. or

Digitized by Google

5in. deep, and the roads rather badly paved with macadam. Under circumstances described as the worst such a vehicle would be likely to encounter, the vehicle required only an average rate of consumption per ton-mile of 114 watt-hours, the average watt-hours per car mile being 193. The total distance covered was 13·4 miles, this taking 1 hour 37 minutes, the average speed being 8¼ miles per hour. The open-circuit voltage at the end of the journey had dropped from 96 to 89 volts, and the running voltage from 91 to 86½ volts. In conclusion, the author gives a table which is a *résumé* of 12 separate tests with four different vehicles. In this case the watt-hours per ton-mile vary from 68·79 to 89·42, the average being about 80. The average speeds of the vehicles varied from 9·68 to 11·31 miles per hour. He concludes that from these tests it would seem as though electric vehicles designed for use in light delivery service can be expected to cover at least 22 miles on one charge of battery at an average speed while in motion of at least 8·5 miles per hour under ordinary service conditions when carrying the average load required of vehicles in this class of service. This they can be expected to do with an average rate of power consumption seldom exceeding 115 watt-hours per ton-mile, and with an average battery efficiency not often less than 70 per cent. if the running voltage is not often allowed to drop below 1·75 volts per cell on a trip—this when the vehicle is equipped with solid rubber tyres. Under adverse conditions, however, the range of such electric vehicles would seem to be not more than about 11 miles for one charge.

High-Voltage Cables.—An article in *Cassier's Magazine* for November, by Mr. Wm. Mavor, jun., on "High Tension Electric Cables as used in the United States," is somewhat disappointing from a technical point of view to the reader who knows anything of cable manufacture. This is so because the author, instead of assuming a certain amount of knowledge on the part of his readers, gives a vast amount of well-known information which crowds out the expert description of the high-tension cables which we should like to have seen. We gather, however, from the article that both indiarubber and paper are used by cable manufacturers in the States. The use of indiarubber has practically ceased in this country for cables under our streets, and it is doubtful if ever any large contracts will again be given in England for rubber-covered cables. The next point we notice is that for distribution work the Americans favour three-core cables. Each of the three cores is independently insulated with either paper or indiarubber, and when laid up together the space between the three insulated cores is filled up with jute to form a circular section. In a number of cases an insulating jacket of indiarubber or paper is then put round the cable, after which comes the lead covering. As an example, the author gives the following particulars of a cable which is to be used in New York with 6,600 volts. The cross-section of each of the three conductors was half a square inch. The conductors are formed of 37 wires stranded together, and the thickness of the indiarubber insulation round each of the coils is $\frac{5}{32}$in. The insulation put round the cable outside of the three cores is also of the same thickness and material, so that there is always $\frac{5}{16}$in. of indiarubber between any pair of the cores or between any core and the lead. We are surprised to find, however, that the lead covering of the cable is only ⅛in. thick, which, with a total diameter of 2·56in., seems to us to be too thin. A glance at a section of the cable also shows what an advantage would be gained by using segment-shaped cores, as is done by one of our prominent English manufacturers for such work. The author also gives some particulars of a cable to be used for 25,000 volts. Here again indiarubber is used, but the thickness is increased from $\frac{5}{32}$in. to $\frac{7}{32}$in. Although the author states in the heading of his article that he will deal with the testing of these high-voltage cables, there is very little information given as to the way in which this testing is carried out. It is, of course, simple to say that on a 10,000-volt cable an alternating pressure of 15,000 volts is applied for one hour, but, as is well known, the details of how the voltage is turned on have a very great deal to do with the actual stresses set up in insulation. For instance, when 15,000 volts is switched on to a cable, it frequently occurs that an arc will start on a spark-gap which will not discharge under 30,000 volts.

The Manchester Electricity Supply.—We have had brought to our notice some criticisms by Mr. S. Norbury Williams, one of the elected auditors of the city of Manchester, on the working of the Manchester Electricity Committee. These criticisms were published in last week's issue of the *Manchester City News*, and we regret to find that they are largely aimed against the chairman of the committee, Mr. Lloyd Higginbottom. We do not propose here to deal with Mr. Norbury Williams's personal remarks, but there is one point which makes one gravely doubt his capabilities to hold the office of auditor in such an important city as Manchester. This is contained in the twenty-first clause of the so-called remarkable disclosures, and reads as follows: "'Electricity sold under cost price.' You will perhaps be surprised to hear that the Electricity Committee is at present selling electricity to users of motors at less than half the price which you have paid to make it. This may seem astounding. It is time you looked into it carefully. Examine the figures. The cost of production and management, including interest and sinking fund, is 2·87d. per unit. We sell it to the motor people at 1·25d.—that is, 1¼d. In other words, we sell £100 worth of electricity for £43. This works unjustly in many ways. Take one. I know a man who is giving up his gas-engine. Why? He says they make him pay full price for the gas he uses, a price which the Corporation make a profit out of. But he finds he can get electricity for his motor at less than half its cost price, and he takes out of the citizens' pockets the other half. He says the gas-engine makers must look after themselves; he prefers a motor which will run largely at your expense. The figures are striking. In the last financial year, we supplied to consumers, at the 5d. rate, 1,993,000 units, which brought us an income of £41,500; whereas, to the motor users at the 1¼d. rate, we supplied 479,000 units and received only £2,500. One result of this low price is that the demand for motors is constantly increasing. Another singular feature of the matter is this, that when I refer to the book in which are entered the applications for electric power for these motors I find, under the heading 'Fitter's Name,' that the name of the firm of Higginbottom and Mannock stands opposite 23 motors. This does not include the cases in which this firm is the sub-contractor." This criticism shows that Mr. Williams has no idea that the cost of electricity supplied to motors may be less than that supplied to electric lamps. That this is so is well known to all electrical engineers, as the cost of supply to any particular class of consumer is largely influenced by the number of hours during which that consumer takes his electrical energy. So much has been written on this subject that we need hardly go into figures again, but we must strongly dissent from Mr. Wilson's criticisms of the action of the Manchester Electricity Committee on this head. It would be well if he had taken the trouble to enquire from Mr. Wordingham as to this point before making such unwarrantable charges as he has done.

BURY ST. EDMUNDS ELECTRICITY WORKS.

The history of the town of Bury St. Edmunds goes back as far as that of any place in England. Thus, according to Camden, in the time of the Romans the name of this place was Villa Faustini, which in Saxon times was changed to Bederick-gueord, or Bederick's Court. In the early days of the introduction of Christianity, King Sigebert built a religious house here; but when King Edmund was killed by the Danes and translated here, and a large church built in honour of him, it began to be called St. Edmundsbury—and, for

THE MAYOR OF BURY ST. EDMUNDS
MR. T. SHILLITOE.

shortness, Bury. Canute built the church anew, enriched it, brought in the monks and their abbot, whence it became an established monastery. The history of the monastery till the dissolution is the history of the town. As one would

MR. CHARLES OLIVER, CHAIRMAN OF ELECTRIC LIGHTING COMMITTEE.

accordingly expect, there are numberless relics of this old monastery, illustrations of some of which we give herewith. The history and legends connected with the founding of this monastery, and with St. Edmund himself, are numerous and of great interest to the antiquarian. The story goes that when he was killed by the invaders of England, his head was cut off by them, and that his people only succeeded in finding the head again through the assistance of a wolf.

The position of Bury St. Edmunds leaves nothing to be desired. As Leland says: "A city more neatly seated, the sun never saw, it hangs so curiously upon a gentle descent, with a little river upon the east side; nor a monastery more great and stately, whether one consider the endowments, largeness, or unparalleled magnificence. One might even think the monastery itself were a city, so many gates has it (some whereof are of brass), so many towers, and a church than which nothing can be more magnificent; as appendages to which there are three more, of admirable beauty and workmanship, in the same churchyard."

At the present time the population of Bury St. Edmunds is about 18,000. The business of the town is almost entirely connected with the agricultural interests of the district in which it stands, together with certain brewing establish-

MR. FRANCIS HASTINGS MEDHURST, THE CONSULTING ELECTRICAL ENGINEER.

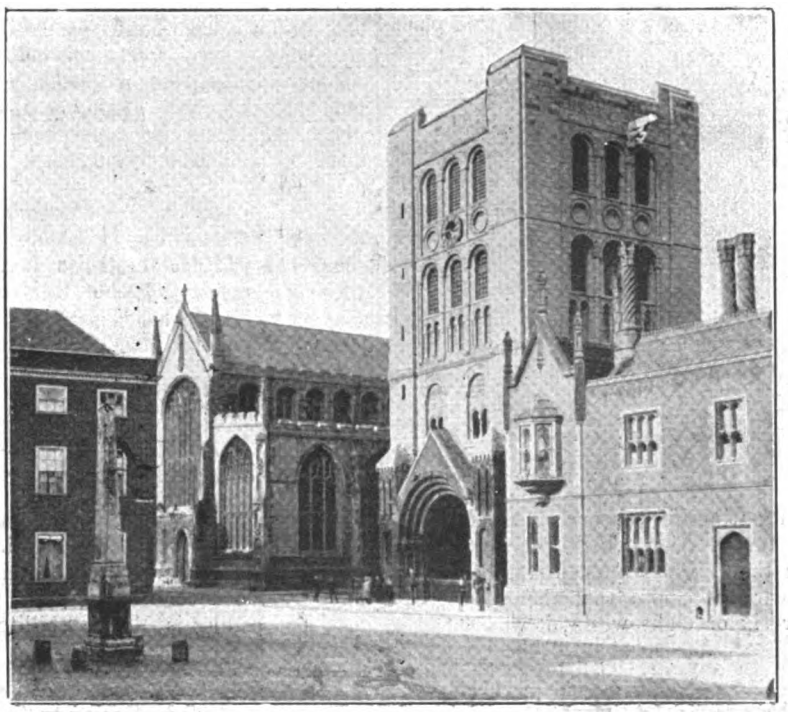
ments and one large agricultural engineering works in the town, where about 400 hands are employed. In consequence of the great age of the various buildings, the jerry wireman will not find things so easy as he would like in the town; thus, we are informed that it is no unusual thing to find that the floor of the room has been raised by additional oak floors, and the unhappy contractor often finds that three thicknesses of solid oak floorboards, not to mention joists, intervene between the floor of one room and the ceiling of

MR. A. H. ROE, BOROUGH ELECTRICAL ENGINEER.

Digitized by Google

the other. Although the population has not been greatly on the increase during recent years, the town is a prosperous one, and is, we believe, noted for the healthiness of the inhabitants. This healthiness also, as is not unusual in small towns, is evidenced by a combative nature, in consequence of which the electric lighting has been seriously delayed. The

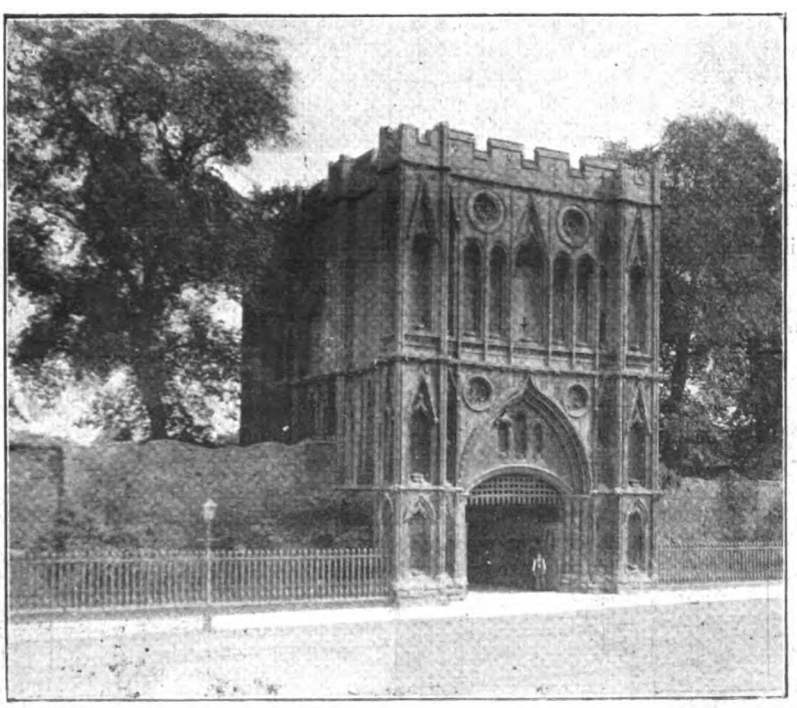
but a brief reference to one of the most curious reasons for the delay will be of interest. In years past the gas company at Bury St. Edmunds were not in the prosperous condition which they enjoy at the present time, and the question even arose as to whether they might not suspend operations, and by so doing put the public streets in darkness. In order



THE NORMAN TOWER.

Council, however, are to be congratulated on the sound policy adopted, by which they are now in possession of an electric lighting undertaking which bids fair to be not only a boon to the town, but also a good financial success. It it noteworthy that the surrounding towns of Cambridge, Newmarket, and Norwich have allowed their electric lighting arrangements to get into the hands of companies.

that this should not be the case, the Corporation were advised to advance to the gas company £2,000 free of interest on the consideration that the then existing gas lamps were always lighted by the gas company at cost price. The other curious provision in connection with this loan was that it could only be returned on the joint consent of both the gas company and the Corporation. We believe that the wording



THE ABBEY GATE.

The supporters of the municipal electric lighting, amongst whom the present chairman of the Electric Lighting Committee, Councillor C. Oliver, is one of the foremost, have had a very hard fight in order to carry their views as to the best course to be adopted in the town. Now that they have been successful it is not well to rake up old sores,

of the agreement also was rather vague and indeterminate, so that the exact meaning of the term "existing gas lamps" even could not be absolutely fixed. It seems, however, to have been assumed that if the Corporation put down an electric lighting plant and lit the streets themselves, the gas company would have to return the loan, as the gas lamps in

Digitized by Google

question would not be used. Apart from this, there were many townsmen who used the whole weight of their influence against the municipal electric lighting scheme. The outcome of the whole matter was that Mr. F. Hastings Medhurst had his report adopted, and on the enquiry by the Local Government Board succeeded in getting his scheme carried through with the exception of that portion which dealt with the street lighting. Seeing that Mr. Medhurst first reported in the beginning of the year 1896, and that the station has only been supplying for six or eight weeks, it will be seen that the obstructionists have been successful in retarding very considerably the introduction of the electric light to Bury St. Edmunds. Still, all is well that ends well, and we are sure that the townspeople will find that even if they are gas shareholders, their interests have been well served in the success of the efforts of the Electric Lighting Committee and their consulting electrical engineer.

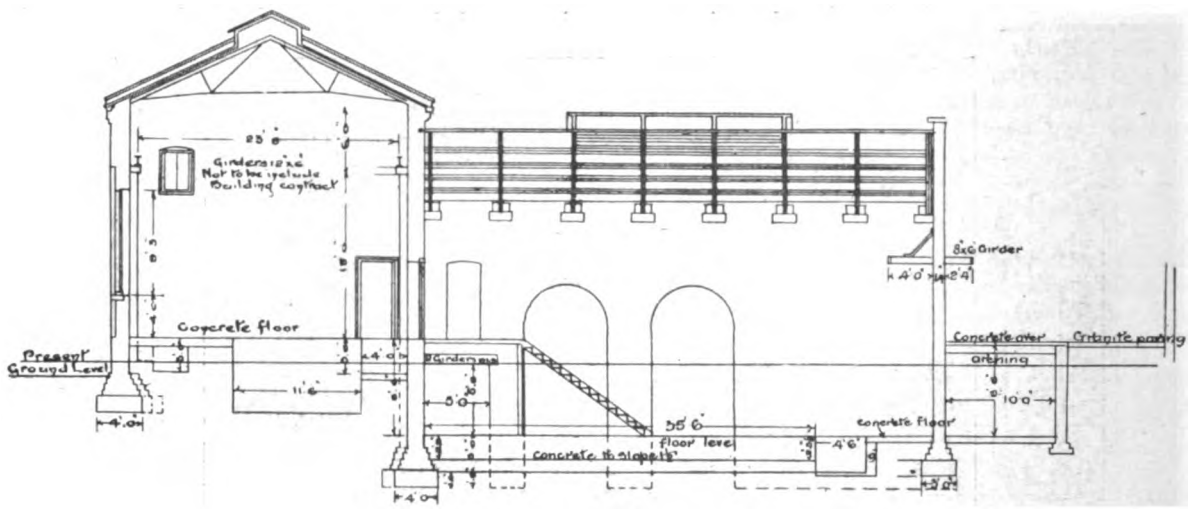


FIG. 1.—Section of the Electricity Works Buildings.

The present composition of the Electric Lighting Committee is as follows: Councillor C. Oliver (chairman), Alderman E. W. Lake, Councillor John G. Oliver, Councillor J. Gough, Councillor W. Jaggard, Councillor T. Shillitoe (mayor), Councillor E. E. Hunter, Councillor W. D. Paine. Of these gentlemen, Mr. Charles Oliver, the chairman, has occupied that position for two years, and much of the success of the undertaking is due to his exertions. He was the first to introduce electricity into the town, having put down a gas-driven plant in 1895 at his business premises. The Corporation is fortunate in obtaining the services of a chairman for the Electric Light Committee who has made a special study of electrical matters. The Mayor, who for the year just ending is Mr. T. Shillitoe, was elected a member of the Council in 1892, taking the seat rendered vacant by the death of his father, who represented the same ward for several years. The Mayor by business, trading under the title of Messrs. Shillitoe and Son, is a contractor, and has carried out many very important public and other works,

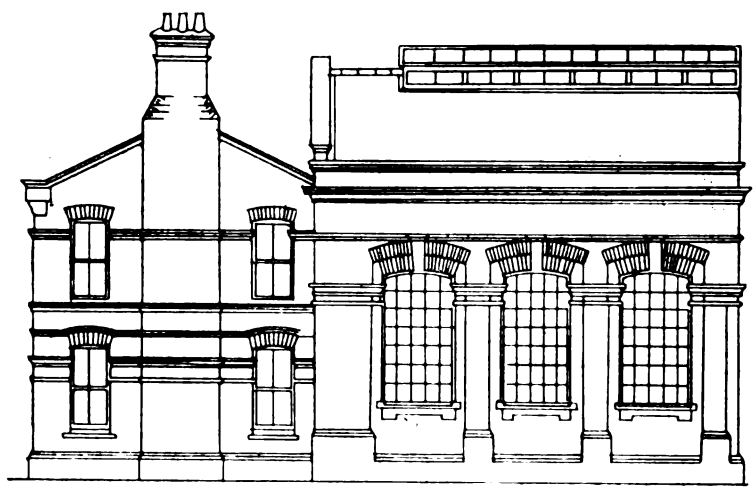

FIG. 2.—Front Elevation.

FIG. 3.—Side Elevation.

amongst which are the first block of the new Admiralty Offices, the National Portrait Gallery, the new head offices of the Metropolitan Asylums Board, the Grand Hotel at Clacton, and is still engaged on the Westminster Cathedral and the West Ham Infirmary. With all this work he has not missed a meeting of the Council, and has attended most of

Digitized by Google

the various committee meetings, and his practical common sense has been of great value to the Electric Lighting Committee in carrying out their work.

When it was decided to erect the works, the question of the most suitable site was naturally one of the first consi-

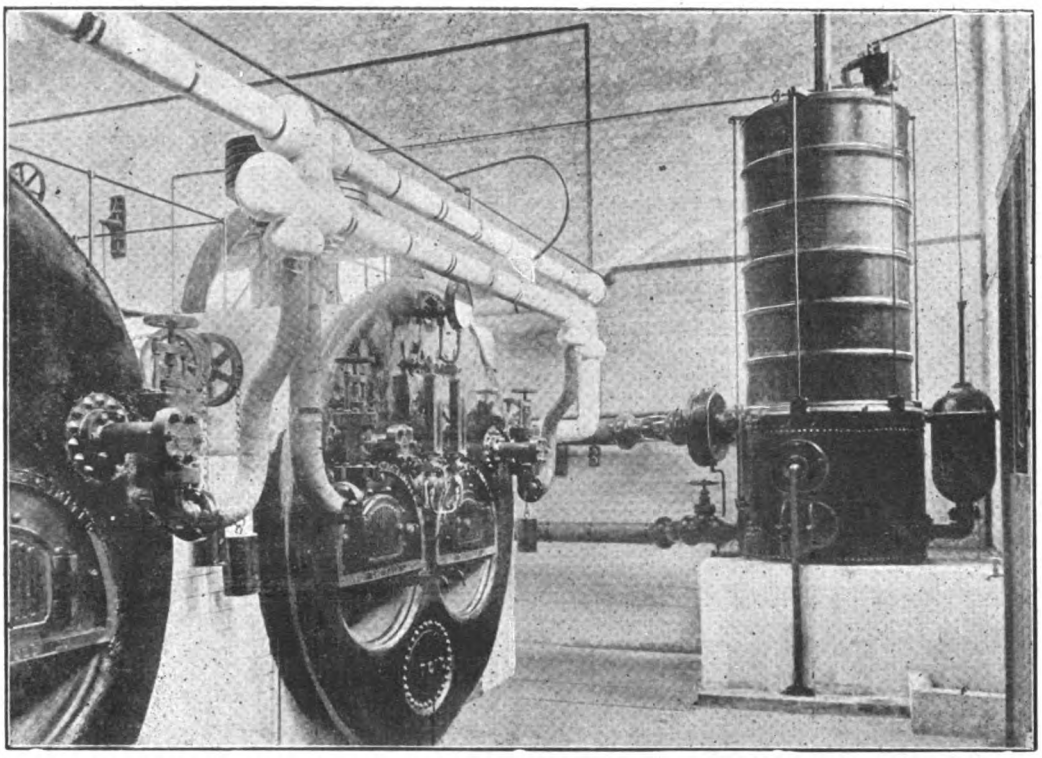

FIG. 4.—View of the Boiler Fronts and Feed Heater.

derations to which Mr. Medhurst had to give his attention. After considering the relative advantages of land to be had in various parts of the town, it was decided that it would be best to establish the works on a large piece of Corporation land at the back of the markets. A portion of this land was already occupied by the buildings of the Corporation waterworks department, and the electricity station has been erected next to these. The site is very central, and consequently the length of feeders is very small, the only drawback to the site being that all coal has to be carted from the railway station, a distance of three-quarters of a mile. Ample room is available for extensions, and temporary ends have been left on both the boiler-house and engine-room for this purpose.

The close proximity of the waterworks to the electricity works is of advantage, and it goes without saying that the Corporation are using the electric light at the present time in their other departments on the same site. It is also likely that in the near future the pumps in connection with the waterworks will be partly driven by electric motors, so that it will not be necessary to keep two sets of boilers under steam in the daytime. The buildings which are now erected on this site were designed by Mr. Medhurst, and are shown in section in Fig. 1, while Figs. 2 and 3 give elevations and sections of the same, from which some idea of the type of building can be obtained. The engineer's office, test room, and accumulator room are placed on the first floor, and in

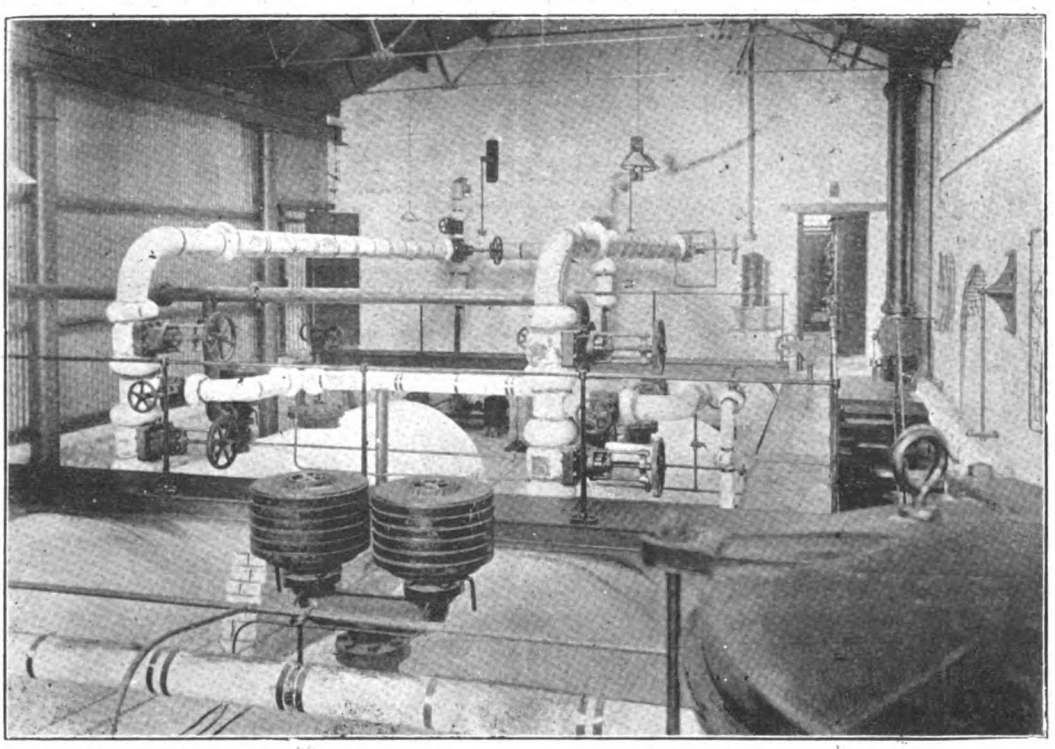

FIG. 5.—The Boiler Tops, showing arrangement of Steam Pipes and Platforms.

Digitized by Google

this way the ground space covered has been saved. The engine and boiler house are provided with temporary ends for ease in extension, and we think from the load already obtained in Bury St. Edmunds that it will be necessary in the near future, probably next year, to extend the building in order to provide room for more machinery.

The Steam-Raising Plant.

The most striking feature about the arrangement of these buildings, and one which cannot be too highly recommended, is the arrangement of the boilers. It will be seen from the drawing that a large excavation was made to receive these boilers, so that they are at a much lower level than the engine-house. The advantages are twofold. Perhaps the greatest is that the coal which is brought in carts to the station can be thrown directly down into the bunkers situated at the back of the firing floor. These bunkers hold a very considerable quantity of coal, which is readily accessible to the firemen, and there is no question of raising coal until it is actually to be thrown into the furnace by the firemen. In Fig. 4 a view is given of the firing floor, the bunker doors being at the extreme right hand of the picture, while the feed-water heater is seen directly in front. The actual cross-section of the coal bunker is 8ft. 6in. high by 10ft. wide. Another advantage of sinking the boilers is that the platform over the same is at exactly the same level as the floor of the engine-room. This platform can be seen in Fig. 5, which was taken from a doorway just above the feed heater. The open door seen at the end of the platform leads direct into the engine-room. It will be seen from these illustrations that all the valves in the steam-pipe range are accessible from this platform, and that they can be quickly got at by the engine attendant in case of need. The iron stairs seen just over the feed heater lead down to the firing floor.

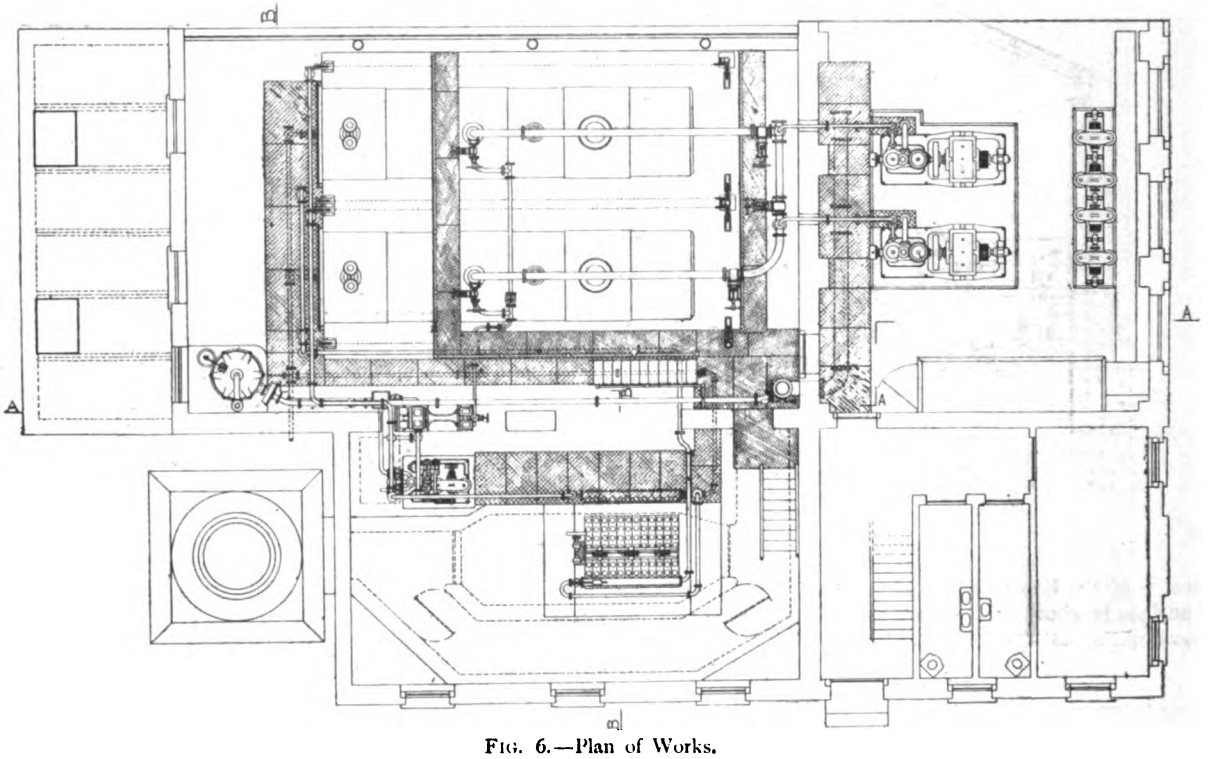

Fig. 6.—Plan of Works.

There are at present two boilers fixed, each 28ft. long by 7ft. in diameter. These are supplied by Messrs. Davy Bros., of Sheffield, and are designed to work at a boiler pressure of 150lb. per square inch. They have each two flues 2ft. 9in. in diameter. The whole of the material used in the construction of these boilers is Siemens-Martin's steel. The boiler mountings supplied can be seen in Fig. 5, from which it will be gathered that there are the usual number. They are practically all of Hopkinson's make. The position of these boilers in the main building can be seen from Figs. 6, 7, and 8. Fig. 6 gives a plan of the whole

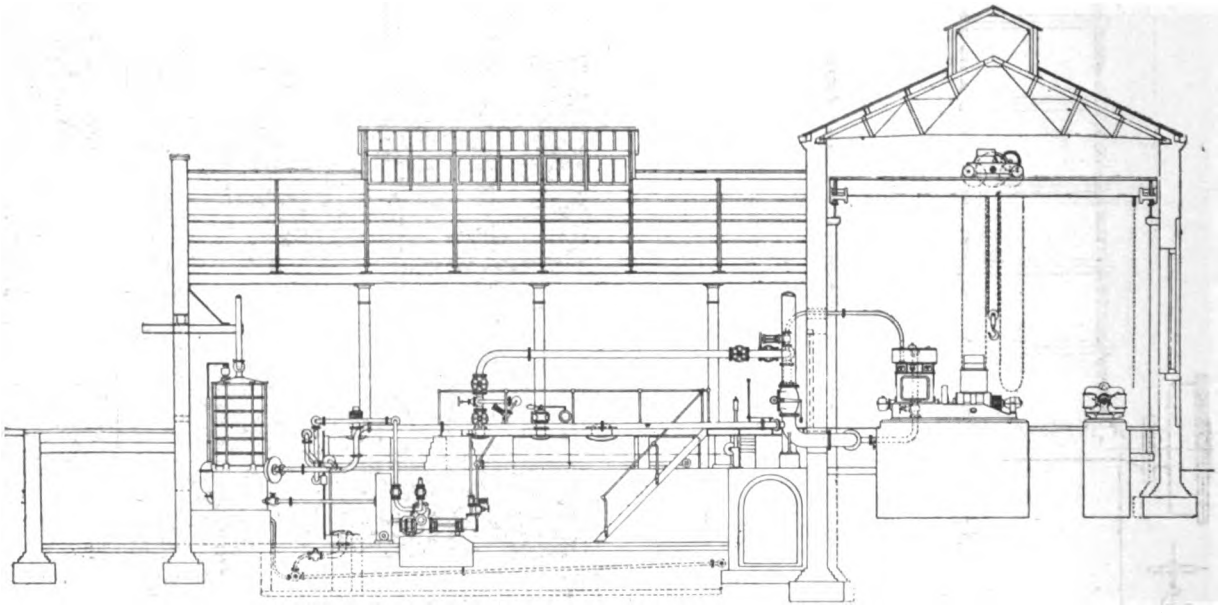

Fig. 7.—Sectional Elevation through the Works.

Digitized by Google

works, Fig. 7 is an elevation which shows a section through the station, and Fig. 8 is a front elevation and section in order to show the boiler fronts and the economiser. This

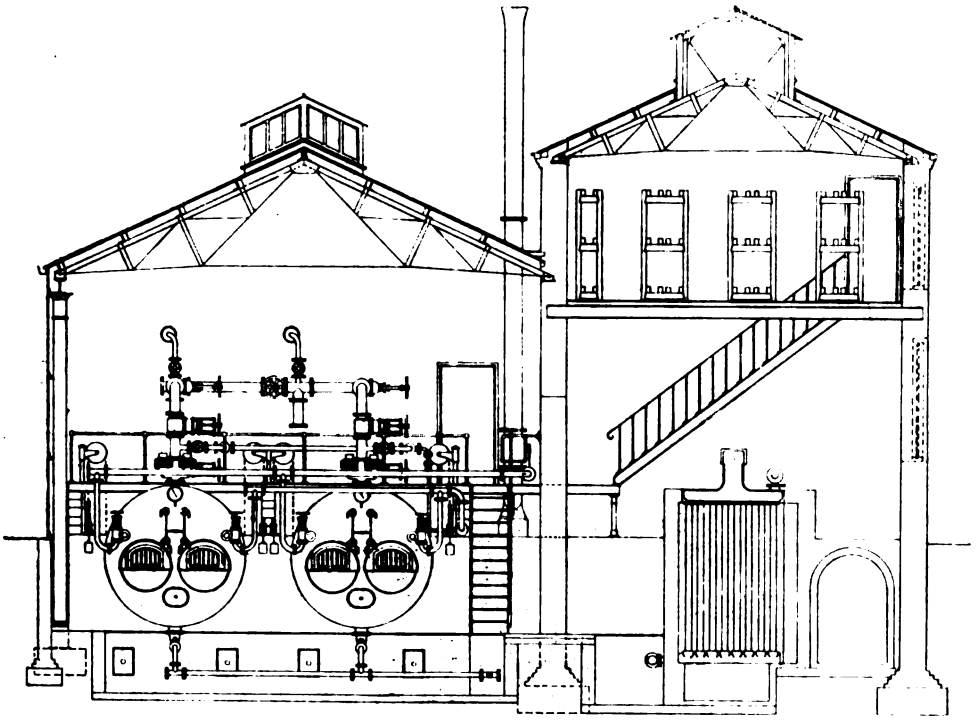

FIG. 8.—Boilers and Economiser.

economiser is of the Green type, and contains 96 tubes. The heating surface is about 720 square feet. The construction of the economiser is specially adapted for working at high

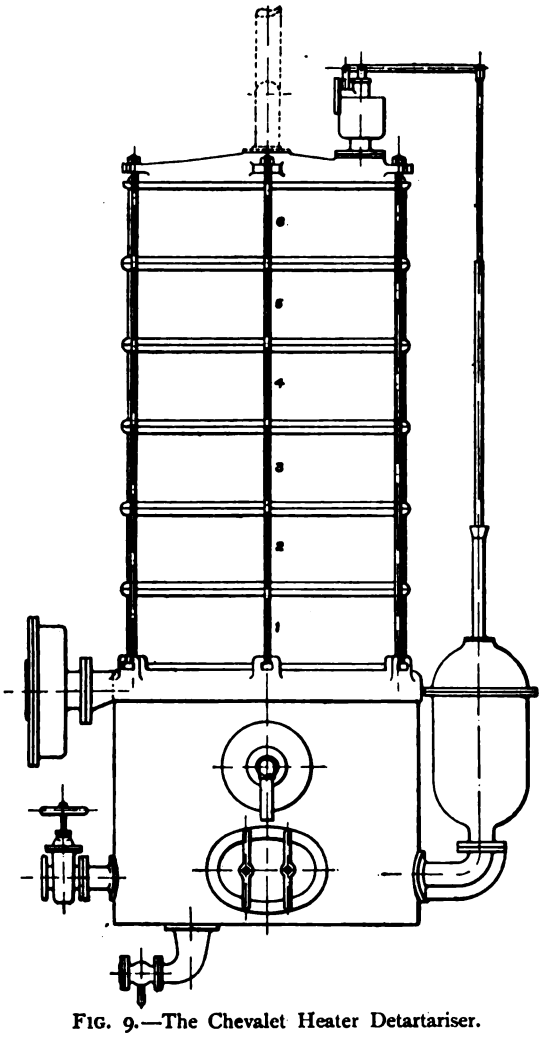

FIG. 9.—The Chevalet Heater Detartariser.

pressures. The economiser is fitted with internal lids on the top boxes, and also with patent access pipes at the bottom to facilitate the cleaning out.

The steam and exhaust pipes were all supplied by Messrs. J. Fowler and Co., of Leeds, who are to be congratulated on the high character of the work carried out. The branches to each boiler from each steam-pipe, as well as the steam-pipes themselves, are 6in. diameter. The connections from the engines to the main steam-pipe are 3in. diameter. The exhaust is of cast iron, 12in. in diameter, having an automatic relief valve to atmosphere, with a branch to the

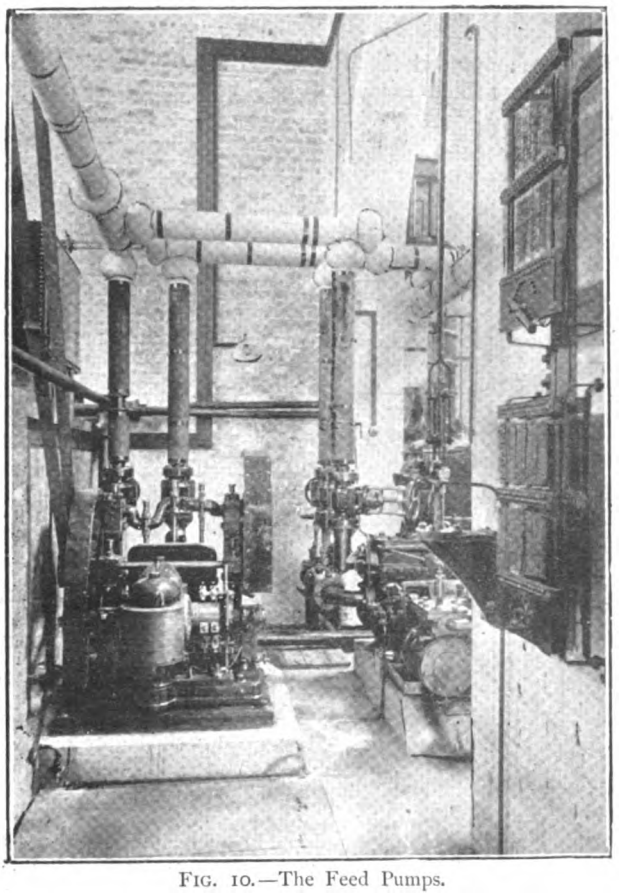

FIG. 10.—The Feed Pumps.

heater. This heater, which is of the Boby type, is well seen in Fig. 4, but is shown more in detail in Fig. 9. The name of the apparatus is the Chevalet heater detartariser. This consists of a series of trays placed one above the other, through which the water trickles. The outlet from one tray to another is by means of a tube covered over by a

Digitized by Google

movable cap of larger diameter. The water-level thus gives a slight seal. The exhaust steam from the engines is admitted into the lower tray and mixes with the water as it ascends through these various tubes and under the edges of the inverted caps. In this way the water is heated up to the boiling point, and the hard matter which would have been deposited in the boilers is thrown down in the trays. Owing to it not being subjected to any high temperature, as is the case when the heat passes through it in a boiler to get to the water, this deposit is not difficult to remove from the heater, as it is quite soft. The heater in question is capable of delivering 540 gallons of water per hour heated up to boiling point. The feed pumps are in duplicate, as can be seen in Fig. 10. The one consists of an electrically-driven feed pump, the motor of which also drives the scrapers of the economiser. This electrical feed pump is able to deliver 1,000 gallons of water per hour against the boiler pressure. The duplex steam-pump, also seen in the illustration, is able to deliver 2,500 gallons per hour. The whole of the steam-pipes, the exhaust pipe in the engine-room, feed pipes, the boilers and boiler fronts, have been most carefully covered with non-conducting material to prevent loss of heat, the covering used being of the magnesia type. It was found that until the boiler fronts were covered the temperature of the stokehole was excessive, owing to there being no through draught.

The Engine-Room.

The engine-room is 25ft. broad by 35ft. long, and, as we mentioned above, we think that the length will have to be extended in the near future. The whole of the plant contained in this engine-room was supplied and erected by Messrs. J. Fowler and Co., of Leeds. As will be seen from the plan, and also from the photograph, Fig. 11, the switch-boards occupy one end of this engine-room. The balancing and boosting dynamos are placed near the window at the left hand in the illustration, while the two steam dynamos are on the right-hand side. These machines are each of 60 kw. capacity. The engines were made by Messrs. Belliss and Morcom, and are of the usual high-speed type manufactured by that firm. One of these engines is shown in end and side elevation in Figs. 12 and 13. The dynamos coupled to these engines were made by Messrs. J. Fowler and Co., and are each capable of giving 130 amperes at 460 volts. The normal speed of the sets is 500 revolutions per minute. They can provide an emergency load of 66 kw. for two con-

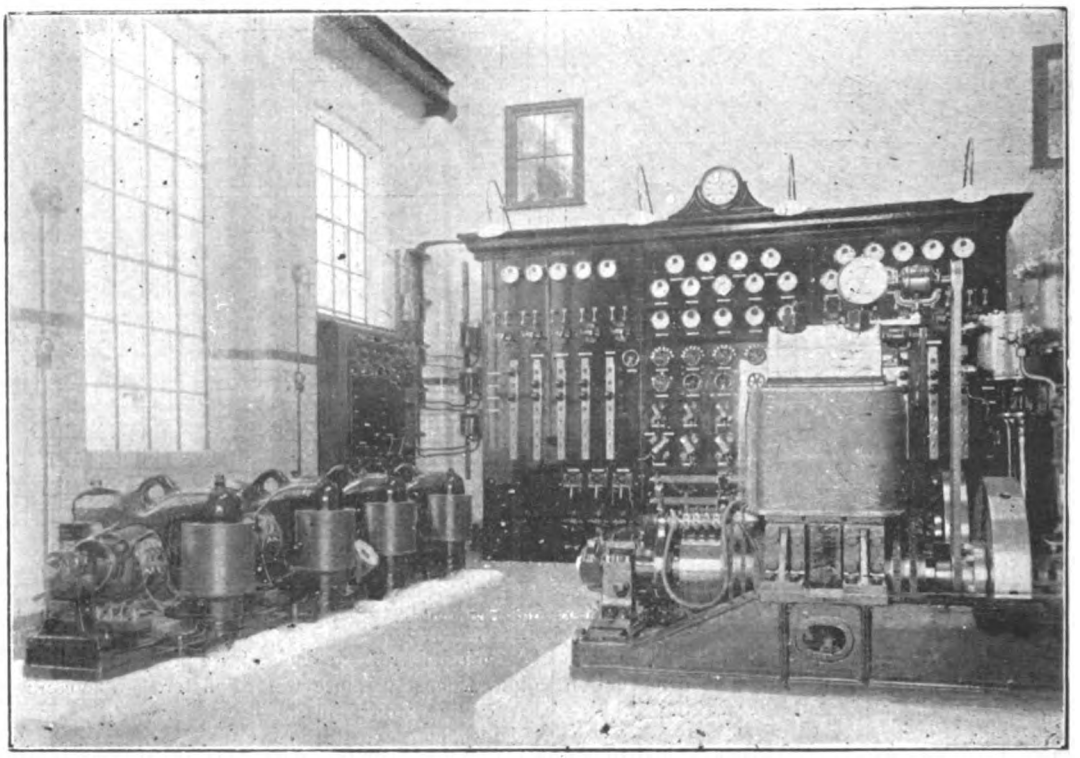

Fig. 11.—View in the Engine-Room at Bury St. Edmunds.

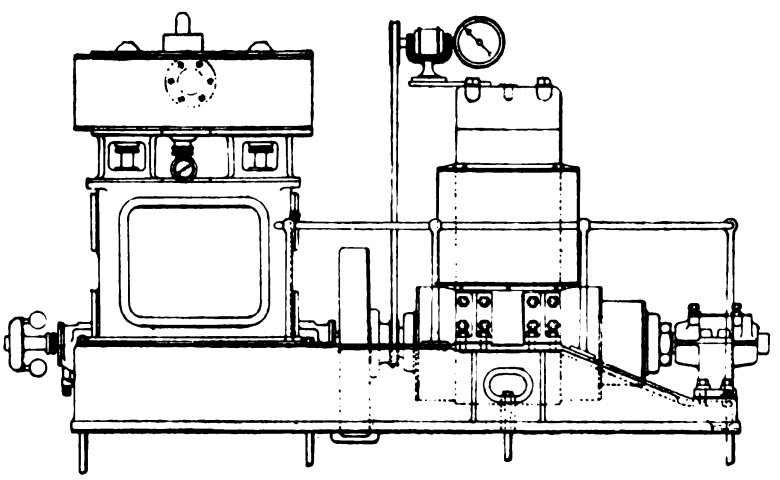

Fig. 12.—The Belliss-Fowler Steam Dynamo.

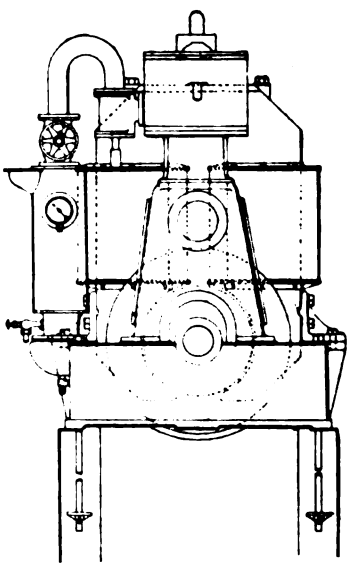

Fig. 13.

Digitized by Google

secutive hours with 10 per cent. extra steam pressure. The balancing and boosting dynamos are, as is usually the case, connected on a continuous shaft, the two balancing machines for the three-wire network being in the middle and one booster at each end. Each of these boosters is capable of giving 100 volts when taking the charging current of the battery. A good view of the two steam dynamos is shown in Fig 14.

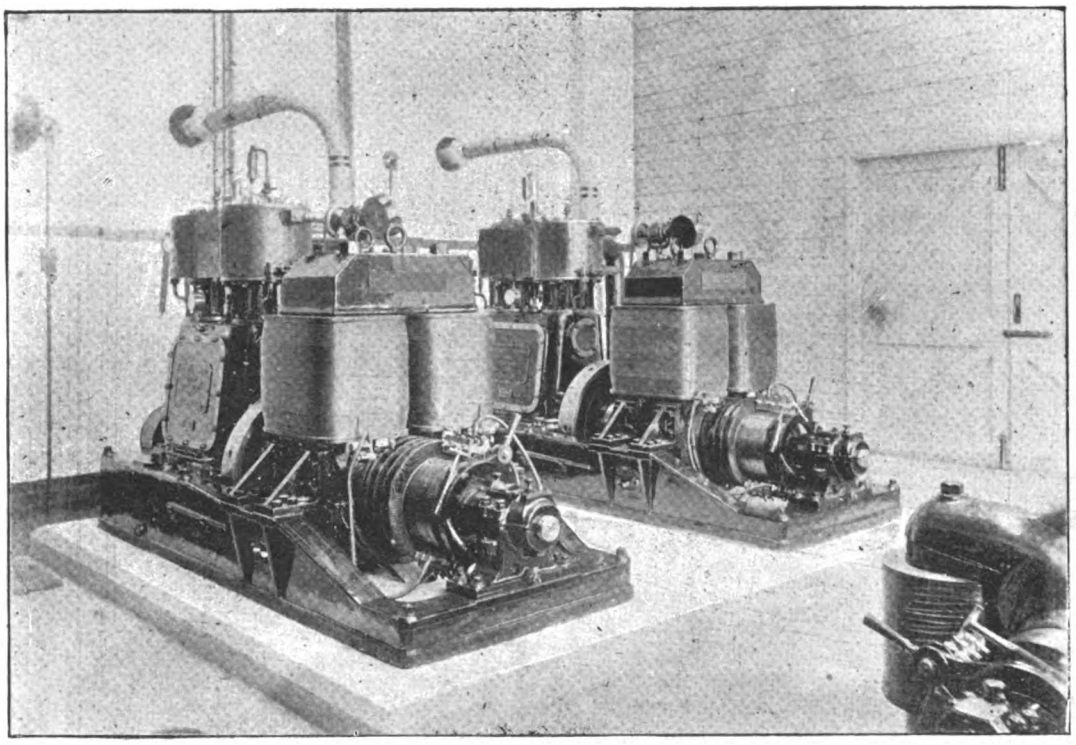

FIG. 14.—View of the Two Steam Dynamos.

THE SWITCHBOARD.

The switchboard is of the plug type, and is of larger and handsomer design than is usual for a station of this size. It consists of three panels, the centre one containing the regulators, instruments, and switches for the balancers, boosters, and battery, the other two arranged as positive and negative, containing the feeder and dynamo bars, instruments, and switches. There is also a switchboard on the left-hand side of the main board, which deals with the station circuits and with the supply of other departments on the same site. The diagram of connections used with the switchboard is shown in Fig. 15, while Fig. 16 is from a photograph taken behind the switchboard. Mr. A. H. Roe, the resident engineer, has arranged his mains at the back of the switchboard in a very neat way in order that there may be a free floor space. With this end the floor is made hollow and bridged over with York stones, which can be easily lifted by means of handles. These handles are of the usual T section, and are arranged to slip back into a recess in the stone when they are not being used. It will be seen from the last illustration that certain of the regulating switches are not mounted on the board itself, but on the wall at the back. In this case the spindle of the switch handle is carried right to this back wall, as can be seen in the photograph.

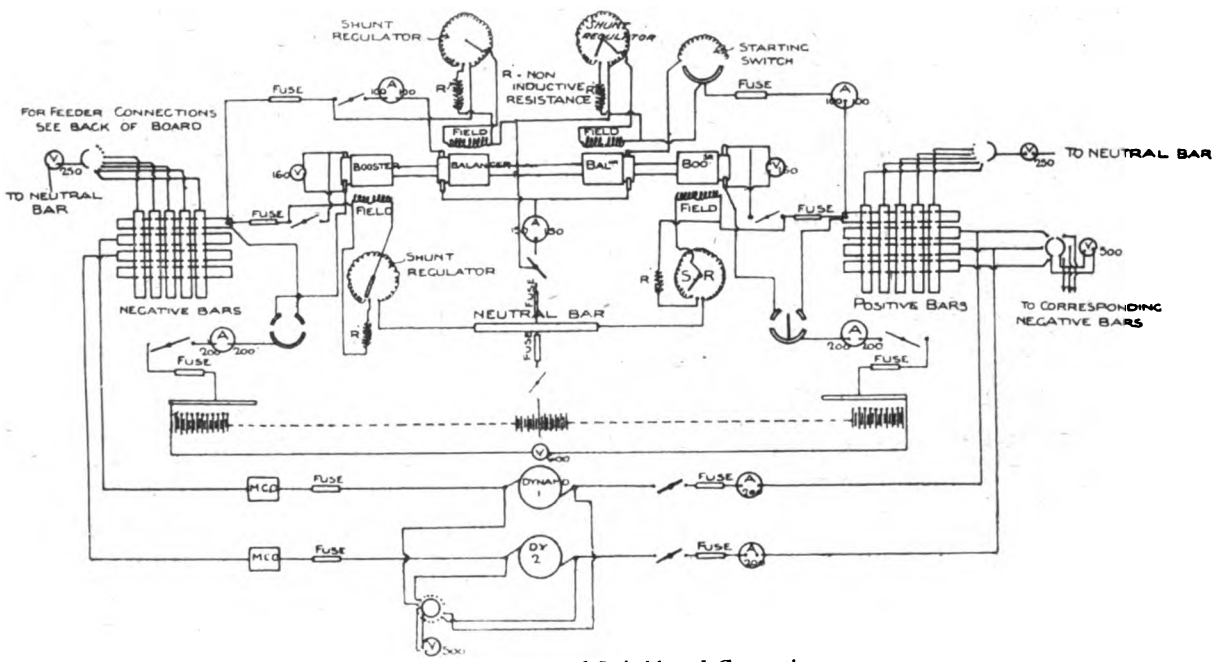

FIG. 15.—Diagram of Switchboard Connections.

ACCUMULATORS.

The accumulators are placed, as mentioned above, on the first floor, in a room 32ft. long by 92ft. broad. The cells were supplied by the Electrical Power Storage Company, and 252 have been fixed. They are placed in double three-tier stands, the stands being of cast iron, with wooden bearers

Digitized by Google

for the cells. The guaranteed discharge rate of the battery is 500 ampere-hours when discharging over 10 hours.

MAINS.

The contract for the mains was placed with Messrs. Callender and Co., who have laid everywhere triple concentric armoured cable, placed direct in the ground. Fig. 17 shows a plan of these mains; the circles in this illustration denoting feeder boxes, while the stars are the arc lamps which are about to be erected as the first instalment. These will be run eight in series off the two outside wires. Up to the present three feeders have been laid, with a collective length of about 3,000 yards. These feed into the network at Brentgovel-street, Angel-hill, and Westgate-street, the two latter having a sectional area of ·2 for the outers and ·1 for the middle, and the former a sectional area of ·1 for the outers and ·05 for the middle. From the feeding points three-core $^{7}/_{20}$ pilot cables are led back to the station. The distributors laid up to the present time have a total length of about 5,000 yards, and the sectional area of these cables is ·125 for the outers and ·06 for the middle conductor.

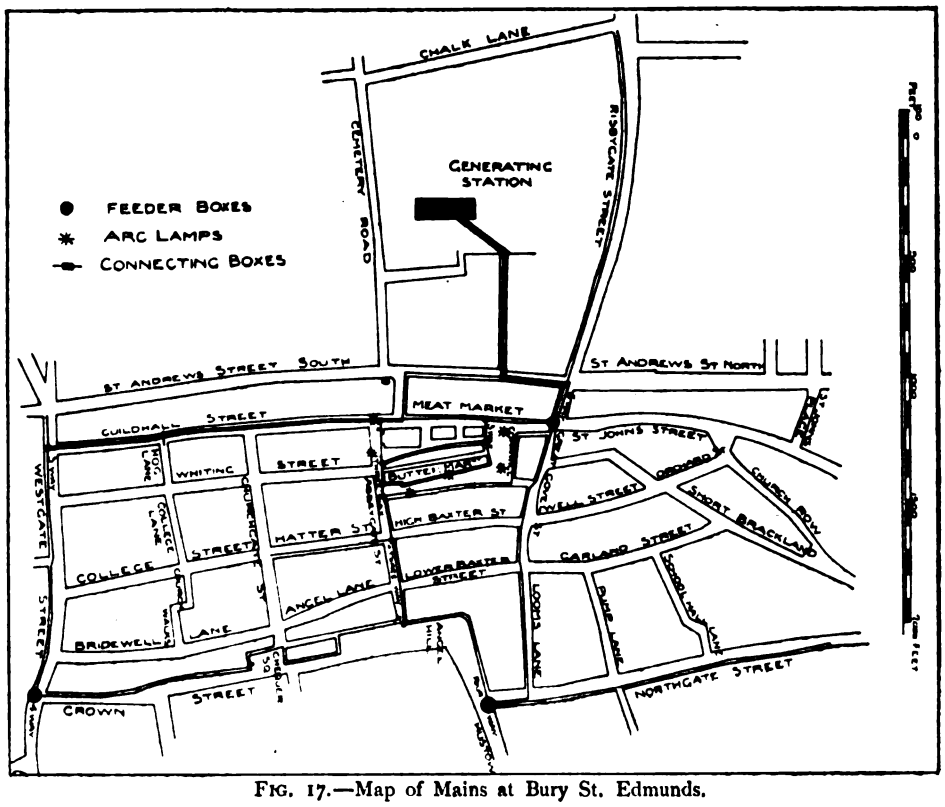

FIG. 17.—Map of Mains at Bury St. Edmunds.

Fourteen feeder and disconnecting boxes are placed in convenient positions, and three fuse boxes have also been put in with a view that in the event of a breakdown on the mains only one-third of the town would be affected. As before mentioned, a very comprehensive scheme was prepared for removing the whole of the gas lamps used for lighting the streets and substituting arc lighting, but this was cut out of the scheme by the Local Government Board owing

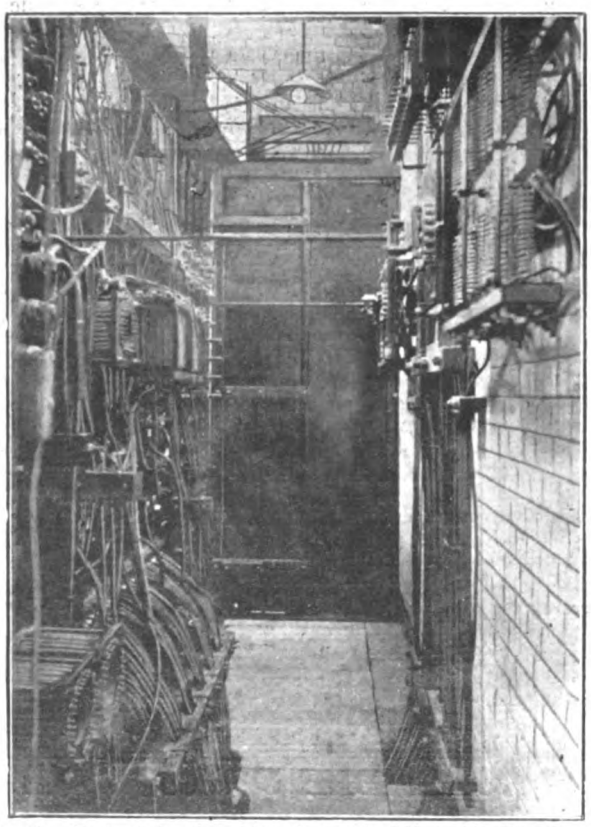

FIG. 16.—Back of the Switchboard, showing Moveable Flagstones.

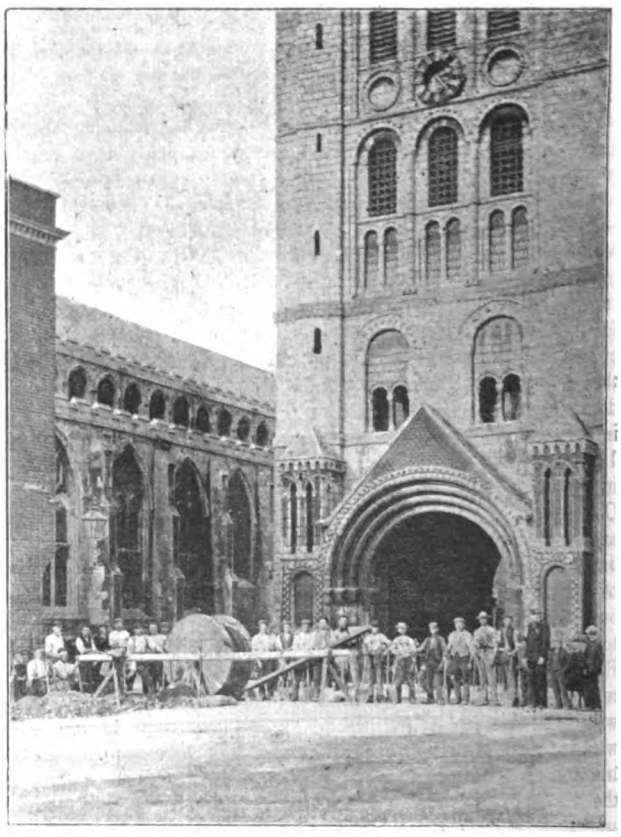

FIG. 18.—Main-Laying near the Old Tower.

Digitized by Google

to the very strong opposition offered to the whole scheme at the enquiry, the Local Government Board deciding that the private lighting should be undertaken first. Fig. 18 shows a view of these mains being laid.

Supply.

Owing to the delay on the part of the contractors supplying the battery, the Corporation have been enabled to give only a temporary supply (commenced on the 28th of August) up to the present time. This has so far given excellent results. Now that the battery is completed, a continuous supply will soon be available. The total number of lights connected up to the present are equivalent to 1,950 8-c.p. lamps, and upwards to the equivalent of another 1,000 8-c.p. lamps will soon be added. The applications for a supply still come in very steadily, and there is little doubt that the financial position of the undertaking will soon reach a satisfactory state. The gas supply is in the hands of a local company, and as the price charged is 4s. per 1,000 cubic feet, the new illuminant at a charge of 6d. per unit competes on most favourable terms. Owing to the opposition when the scheme was mooted, none of the streets are lighted electrically. The Local Government Board, have, however, recently sanctioned the use of £800 for this purpose. Eight 10-ampere arcs are to be placed in the centre of the town, and 20 incandescent pillars in Risbygate and St. Andrew's streets. The total capital outlay up to the present is £15,000, and comes within the original estimate.

Workmen's Cottages.

At the present time workmen's cottages are almost unobtainable in the town, and with a view to overcome this difficulty, Mr. Roe advised the Council to build two cottages next to the works. This idea is now being carried out, and the cottages will be occupied by two of the staff at the works. This arrangement offers many advantages, as not only do the occupants of the cottages obtain comfortable quarters in the most healthy part of the town, but the electricity department have the advantage of having some of the staff always on the spot—a great consideration where the staff is necessarily small and the buildings have to be left unattended for a considerable length of time.

The Engineers.

As mentioned above, Mr. F. Hastings Medhurst has designed and superintended the carrying out of the whole of the work from the buildings to the mains, and the town is to be congratulated on the result. The contractors have also done their best, and have loyally stood by their contract pledges. Mr. Bennett has acted as clerk of works for Mr. Medhurst. The principal contractors, Messrs. Fowler and Co., of Leeds, have been represented on the spot by Messrs. Anson and Moore, while Mr. S. B. Collard superintended the main laying for Messrs. Callender and Co. When the work was nearing completion, applications were invited for the post of assistant engineer. Out of a large number of applicants the committee selected Mr. Arthur H. Roe, and they are to be commended for their choice, as he has already done much to increase the popularity of the electric light in Bury St Edmunds. His past experience, extending over 11 years, is as follows: After serving an apprenticeship in London, Mr. Roe entered the service of the P. and O. Steam Navigation Company as a sea-going electrical engineer, and in this way visited India, China, and Japan. He finally had charge of the electrical equipment of the hospital ship "Coromandel," when that vessel took out Prince Henry of Battenberg on his ill fated expedition to Ashanti. Mr. Roe then transferred his services to the Bradford Corporation, and during the three years he remained the electric lighting undertaking made great headway, the system of supply being changed over to the three-wire, a new generating station erected and equipped, electric traction introduced, and many improvements effected. At the time of his resignation he occupied the post of chief assistant electrical engineer. He was appointed to his present post in January of this year.

In conclusion, we have to thank Mr. Medhurst for the drawings from which our illustrations are prepared, and both him and Mr. Roe for their kindness in placing all available information at our disposal. The portraits reproduced were taken by Mr. J. Palmer Clarke, of Bury St. Edmunds.

THE ELECTRICAL ENGINEERS (R.E.) VOLUNTEERS.

We have received from the officer commanding the Electrical Engineers (R E.) Volunteers extracts from a letter sent by Captain Lloyd, R E, who commands the section of the corps which is now in South Africa, to Major Crompton. From this we gather that Captain Lloyd himself has been appointed deputy-assistant adjutant-general for transport, in addition to his duties with the Electrical Engineers. There is also good evidence in the letter that the corps has not been kept idle, but is being used in many ways in which the ordinary soldier could not be. Thus Sergeant Phillips, Corporal Hossack, Quartermaster-Sergeant Wordmore, R G.A., and three civilian engine-drivers have lately been employed in bringing up from Koomati Poort some of the rolling-stock, of which a large quantity was taken at that place. The lighting apparatus which was taken out has also been well used. Captain Leaf with a detachment, including Sergeant Graham, Corporal Sellon, and Lance-Corporals Peart and Levin, has also gone to Koomati Poort with No. 2 engine and search-light apparatus in order to enable nightwork to be carried on and to bring up captured rolling-stock. Other members of the corps have been employed bringing captured dynamos, engines, and boilers from Waterval. Apart from these special duties, Sergeant Phillips, Corporals Hossack and Hodgson, and Sapper Young have been regularly employed on traction work in connection with eight civilian drivers belonging to the Steam Transport. Corporal Sellon, who has been ill in hospital, has, we are glad to state, regained his health, and is now at work in Pretoria. Mr. D. F. Colson, who was amongst the prisoners captured and liberated some time since, and who was connected with the gas and electric lighting undertaking at Leicester, had blood-poisoning and was invalided home. He is now coming home on the "Nubia," which will probably reach England early this month. We are sorry that such an unfortunate incident should have stopped the good work which Mr. Colson appears to have done in South Africa, and we trust that it will not be long before he throws off all traces of his recent illness. It is interesting to note that Captain Lloyd states that the probable date of the departure of the E E R.E V. from South Africa is Nov. 4. Although, of course, no such reception as was given to the C.I.V. could be given to their electrical comrades, we are quite sure that on their arrival in England the members of the electrical profession will extend to them the heartiest welcome in their power.

MANCHESTER ELECTRICITY COMMITTEE.

The Manchester Corporation is now considering a series of allegations brought against the Electricity Committee, and especially against its chairman, by Mr. S. Norbury Williams, one of the elective auditors of the city. These charges appeared in the last week's issue of the *Manchester City News* for last Saturday. They were replied to by Alderman Lloyd Higginbottom at the Council meeting on Wednesday, and a small committee has been appointed to consider the charges as far as they affected Alderman Higginbottom. This committee is to report to a special meeting on Monday next. This promptness is due to the fact that Alderman Higginbottom is the Lord Mayor-Elect of the city of Manchester.

Mr. Norbury Williams's address is somewhat condensed by us owing to its great length, and to the fact that certain clauses affecting the committee as a whole will come up for discussion by the Council at a later date than others. The address is addressed to the ratepayers, and the paragraphs are numbered consecutively. Mr. Williams begins thus:

1. For the eighth time you have elected me to the office of elective auditor for this city, and I beg sincerely to thank you for the confidence you have uninterruptedly reposed in me in these past years. The office is perhaps one of the most responsible, as it is one of the most trying, which devolves upon any man whom you send to represent you in the town hall. This city, which we all love, and for whose good name and pure government we are all so solicitous, now embraces a population of about 550,000 persons, and the turnover in the city treasurer's office during the past year amounted to nearly £8,000,000 sterling. The city is a little kingdom in itself, and one feels it a great honour to represent, in any capacity, so great and so progressive a community.

Digitized by Google

2. When I took office I signed, in the presence of the Lord Mayor, the following declaration: "I, having been elected elective auditor for the city of Manchester, hereby declare that I take the said office upon myself, and will duly and faithfully fulfil the duties thereof, *according to the best of my judgment and ability*." These words have had a great meaning for me, for it is often a most unpleasant and disagreeable task to have to speak out plainly on matters which affect the city's interests, and which sometimes affect also individual members of the City Council. I feel it my bounden duty to report to you now—to you who find all the money which keeps the municipal machine going—upon a matter which concerns one of the committees of the Council, and particularly one of the members of that committee. The news that I had this intention got wind in the town hall, and you would be surprised, if I felt in a position to give the details, at the number and the influence of the members of your Council who have approached me or sent messages to me, with a view to induce me to keep silence, and to abandon my intention of informing you of the facts which I am about to lay before you for your information and for your immediate consideration and prompt action.

3. It is astonishing how the members of your Council cling together for mutual defence, and what great efforts they make to keep from the ratepayers anything which tends to show any weakness or wastefulness in their administration. I have been asked "to consider our good name," "don't make us a laughing stock again," "don't help outsiders to charge us with corruption," and so on, *ad nauseam*. But the words I have quoted in paragraph 2, that I will fulfil my duties "according to the best of my judgment and ability," are ever ringing in my ears, and I must and will be mindful of them, be the consequences what they may. The citizens have an absolute right to know all that goes on in the town hall; they have a right to follow the expenditure of the vast sums received and expended by the Council, even to the last single shilling. And I will never be a party to hushing-up or concealment, whatever may be the influences brought into play with a view to secure secrecy. No member of the Council should assent to any act of administration or to one penny of expenditure upon which the full light of day could not be at once admitted.

4. The section of the Council to which I desire to draw your attention at this moment is the Electricity Committee. This body consists at present of 17 members. Alderman Lloyd Higginbottom is its chairman, and Councillor Bowes its deputy-chairman. Its other members are the Lord Mayor (ex-officio), Messrs. Bax, Gibson, Griffin, Mainwaring, Arrandale, Batty, Bishop, Boyle, Heaketh, Jennison, Lambert, Phythian, John R. Smith, and Matthew Wells. This body was constituted in November, 1897, and then became a separate committee. Previously to that date all operations concerning the supply of electricity to the citizens were carried out through the Gas Committee. Alderman Higginbottom became a member of the Council in 1890, and was at once elected a member of the Gas Committee. In November, 1894, he became its vice-chairman, and retained that office until 1897, when, as before stated, the Electricity Committee became a separate committee. Mr. Higginbottom still remains also a member of the Gas Committee.

5. This clause deals with the great expenditure of money which the Electricity Committee have been responsible for, and which amounts to more than £756,000. It is alleged in this clause that great lengths of unremunerative cable have been laid.

6. This clause deals with the alleged bad management of the committee, which it admits is being looked into by a sub-committee, which the full committee has appointed recently. The report of this sub-committee is still to be considered by the Council.

7. In this clause Mr. Williams alleges that a considerable amount of money, in amounts ranging from £124 up to £1,106, have been spent by the committee or by the engineer without asking for any competitive tenders.

8. Then this sub-committee enquired what increases of wages or salaries had been made in the staff under the control of the electric lighting stations during the 12 months ended June 30, 1900, showing the cases where these increases had been submitted to the committee; and this wonderful discovery is now made that out of 37 men employed in various capacities at this station there have been 29 advances of salary or wages which have never been so much as mentioned to the committee, and of which the greater part of the members are in blank ignorance. Comment, again, is needless.

9. We then come to the appointments and promotions made in the electricity department during the 12 months named in previous paragraph, without the knowledge or consent of the committee. This remarkable list contains 19 names. These 19 gentlemen have all been added to the staff in a quiet unobtrusive way. Nobody knew anything about them, apparently. Not only have they been "taken on," but in 12 cases increases have been made in their salaries, and still the committee have not known a word about it all. These gentlemen include a draughtsman at £195 a year, and nearly all receive £100 a year or more. The thing reads almost like a novel. One could not have thought such a state of things possible. One of the gentlemen in this list, a Mr. John Walton, appears later on in this address, and his name should be noted.

10. In this clause it is stated that discounts have been lost by not promptly paying accounts, and one admitted instance is cited.

11. In the section certain extras to contracts are detailed, and the engineer has quoted to the effect that "a little more consideration might have prevented one or other of the extras."

12. This clause deals with the ordering of goods without tenders being invited, and contains an extract from a report to the sub-committee from Mr. Alderman Higgenbottom, in which it is stated that Mr. Wordingham had been carrying out all that was done under the old *régime* when the electrical undertaking was managed by a sub-committee of the Gas Committee. This Mr. Williams stigmatises as showing that the electricity business has been carried on in an abominably loose way from its birth.

13. In this clause reference is made to members of the Corporation being also shareholders in limited liability companies which have dealings with or supply goods to the Corporation. It seems that Mr. Norbury Williams made certain similar remarks to these concerning one of the aldermen of the Council in 1894, and that the alderman in question left the Council in consequence.

14. (*a*) S. Z. de Ferranti, Limited.—This is a company which manufactures meters and generators. Your Corporation have done a large business with them and given them continuous orders. Since May, 1893, we have paid them £27,225. Mr. S. Z. de Ferranti is also a director of the company marked (*b*).

15. (*b*) The British Insulated Wire Company, Limited.—This company was registered in April, 1897. Its works are at Prescot, and it manufactures electric cables. Large quantities of its wires are being laid under our streets at this moment. Since January, 1896, the Electricity Committee, of which Mr. Higginbottom is chairman, has bought from this company, and paid for, cable to the extent of £44,957. I ask you now to note who are its directors. The chairman is Mr. W. Marriner Brigg, who is also a director of the company marked (*c*). Another director is Mr. James B. Atherton, a brother of Mr. Jacob Atherton, who is named twice below, and is director also of company (*c*). Another director is Mr. S. Z. de Ferranti, who is also on the Board of company (*a*). The solicitors to this company are Messrs. F. J. Leslie and Co. Mr. F. J. Leslie himself is also a director of company (*c*). The London representative of this company is Mr. Jacob Atherton (brother of the director above named). Mr. Jacob is also a director of company (*c*).

16. (*c*) The British Electric Works Company, Limited.—Now we come to the third of this singular chain of companies. You will be much interested in this company, because its chairman is Alderman Lloyd Higginbottom, who is also chairman of our Electricity Committee. It was registered in April, 1899, its capital being £135,000 in £1 shares. Of these £50,000 are preference. The "Directory of Directors" for 1900 says: "Mr. L. Higginbottom, Hill Top, Cheadle Hulme, is a representative of the Manchester Corporation on the Board of the British Electric Works Company." But this is evidently a mistake, as your Corporation cannot be represented on the Board of a private company. And who are its directors? Mr. Lloyd Higginbottom (chairman Manchester Electricity Committee), chairman; Mr. Jacob Atherton, the London representative of company (*b*); Mr. W. M. Brigg, chairman of company (*b*); Mr. T. Goffey; Mr. R. F. Hall; Mr. F. J. Leslie, whose firm are the solicitors to the company (*b*). The company's works are at Aston, Birmingham, but about four months ago it opened a branch in Manchester. And this is how the advent of the new company to Manchester was announced. The *Electrical Review*, in its issue of June 22, 1900, says: "The British Electric Works Company, Limited, have opened a branch in Manchester for the supply of their electrical fittings. They have secured a very central position at 37, Piccadilly, and have engaged the services of Mr. John Walton, who was for several years with the Manchester Corporation electricity supply as inspector of installations. Mr. Walton also had charge of all the testing of accessories submitted to the Manchester Corporation." Now it is necessary to enquire who is this Mr. Walton who has thus joined the Manchester branch of Alderman Higginbottom's company. If you will kindly refer to paragraph No. 9, you will find the appointments and promotions made without the knowledge or consent of the Electricity Committee. One of the gentlemen in that list is the Mr. John Walton named above. Two advances in his salary were made "without anybody knowing," and then we find he has left us and gone to Mr. H.'s company. This transfer would not have been mentioned by me, nor would it have concerned you, except for the unfortunate fact that Alderman Higginbottom is chairman of both concerns. The representatives of three large electrical firms have seen me, and this is what they say: "There is a general

Digitized by Google

feeling amongst all who are engaged in the electrical supply business that the advent of this new company will seriously affect the business of the other existing firms. This feeling is based on two facts: (1) the chairman of the company is Mr. Higginbottom; (2) the new manager is the late assistant to the city electrical engineer here. We consider that free competition is not now possible."

17. The allegation is that Mr. Walton, after his years of Corporation experience, and consequent knowledge of Corporation requirements, will be able to sell to citizens the fittings made by Mr. Higginbottom's company, and that it is but natural that Corporation officials should be ready to pass the fittings of a company of which their own master is chairman! One gentleman who is in the business writes me thus: "In view of the fact that the chairman of the Electricity Committee is the chairman also of this company, is it compatible with municipal probity that he should be interested in a commercial undertaking to which in his official capacity he is able to show favour, to the disadvantage of other business undertakings and of fair trading generally?" I think the citizens will have no difficulty in answering this gentleman's very proper question.

18. Among the shareholders in this company I find:

	Ordinary.	Preference.
Lloyd Higginbottom	500	500
W. M. Brigg	500	500
George Makin (see below)	50	50
Jacob Atherton	—	1,100
Nine members of Atherton family.	2,500	4,900
F. J. Leslie	—	250

19. I would not have entered at such length into the details of this company were it not that it has positively sent in a tender to the Electricity Committee, with a view to supply its fittings to the Corporation. This took place on Sept. 10 last. I have seen the tender. It is simply intolerable that Mr. Higginbottom (as the British Electric Works Company) should be applying to the same Mr. Higginbottom (as chairman of the Electricity Committee) for orders for his wares. Luckily for all concerned, the tender was refused. But it had no business to be sent. This sort of thing must be stamped out. I may say that one thing which greatly enrages competing electrical firms is that "Mr. Higginbottom's fittings," as they are called, are publicly exhibited at our Dickinson-street station.

20. West Gorton Foundry Company, Limited.—Now we come to the fourth and last "link" in the chain. This foundry company is, if I may so call it, a thoroughly "family affair." It is like the Alderman Hugo Shaw company already referred to. It was registered on Jan. 4 last, with a capital of £5,000; £1,800 are taken up. There are 14 shareholders, who include the following persons:

Lloyd Higginbottom	118 shares.
Thomas Mannock (his partner)	118 "
Edward Broome (secretary of company)	14 "
James B. Atherton (see company *b*)	250 "
Harriet C. Higginbottom (Mr. H.'s wife)	40 "
George Makin (her father)	250 "
Thirza Hilditch (her sister)	25 "
Richard Hilditch (Mrs. Hilditch's husband)	75 "
Wm. L. Chew (his partner)	110 "

This company of Mr. Higginbottom's has also, I greatly regret to say, been striving to do business with Mr. Higginbottom's committee at the town hall. On Dec. 4 last they sent in a tender, which was declined. On May 7 they again tendered for materials, but were successful as to only a portion of their tender, and so declined to take up the remaining portion. For the third time, about Sept. 14 last, they again tendered, and were at last successful. The Corporation's materials, value £24 odd, have been delivered to this company, and are found recorded in the "Sundry Sale Book," p. 183. The amount is at this moment still owing to the Corporation. I can explain in a word my view of the situation. It is, that this state of things is abominable, and the only "way out" is that which Alderman Hugo Shaw adopted.

21. You will perhaps be surprised to hear that the Electricity Committee is at present selling electricity to users of motors at less than half the price which you have paid to make it. This may seem astounding. It is time you looked into it carefully. Examine the figures. The cost of production and management, including interest and sinking fund, is 2·87d. per unit. We sell it to the motor people at 1·25d.—that is 1¼d. In other words, we sell £100 worth of electricity for £43. This works unjustly in many ways. Take one. I know a man who is giving up his gas-engine. Why? He says they make him pay full price for the gas he uses, a price which the Corporation make a profit out of. But he finds he can get electricity for his motor at less than half its cost price, and he takes out of the citizens' pockets the other half. He says the gas-engine makers must look after themselves; he prefers a motor which will run largely at your expense. The figures are striking. In the last financial year, we supplied to consumers, at the 5d. rate, 1,993,000 units, which brought us an income of £41,500; whereas, to the motor users at the 1¼d. rate, we supplied 479,000 units and received only £2,500. One result of this low price is that the demand for motors is constantly increasing. Another singular feature of the matter is this, that when I refer to the book in which are entered the applications for electric power for these motors, I find, under the heading "Fitter's Name," that the name of the firm of Higginbottom and Mannock stands opposite 23 motors. This does not include the cases in which this firm is the sub-contractor.

22. This clause begins as follows: Now I come to a matter which to me seems very serious. Perhaps more serious than any of the preceding cases. Alderman Higginbottom is a member of both the Gas and Electricity Committees. Both those committees use large and costly cranes in their works. Alderman Higginbottom's firm (Higginbottom and Mannock) make cranes. The following reads like a simple innocent transaction: "Minutes of the Gas Committee, March 19, 1897.—'Resolved that the tenders of Messrs. F. Pearn and Co., Limited, for the supply of two hydraulic cranes, one for each of the Gaythorn and Rochdale-road gasworks, for the sums of £164 and £190 respectively, be and are hereby accepted.'" Mr. Williams goes on to state that Frank Pearn and Co. do not make cranes, and alleges that they simply acted as agents for Higginbottom and Mannock. In support of this, he quotes a number of workmen's statements to the effect that they worked on the Corporation works erecting the cranes while they received their weekly remuneration from Higginbottom and Mannock.

23. In this clause the same charge is brought respecting the cranes on the electricity works, which, it is stated, were practically supplied from Mr. Higginbottom's firm, but were invoiced through another firm. Here, again, it is stated that the ironwork and rails were actually fixed by Mr. Higginbottom's men. This concludes the list of charges, and Mr. Norbury Williams ends up his case with the following words:

24. "No man can serve two masters. No man ought to be a penny the gainer through his membership of a representative and trading body like our City Council. I have laid before you this regrettable case, and it is for you, through your councillors, to decide what should be done. Is Mr. Higginbottom to become our Lord Mayor? Ought he, with all this network of business connections with the Corporation, to remain a member of that body? You must make up your minds, and that quickly. In my judgment the good name of the city is at stake, and by the decision to be shortly arrived at the country will decide whether Manchester stands on the high plane which it has hitherto occupied, or has descended to the level of those municipalities where selfish ends, and not the commonweal, have been allowed to gain the upper hand. I have dispassionately told you the facts so far as I know them. The serious responsibility of deciding what shall be done rests upon your shoulders."

(Continued on page 631.)

LIGHT RAILWAYS.

The proposed agreement with the North Metropolitan Tramways and Omnibus Company, Limited, for the construction by them of a light railway in the urban district of Cheshunt, has been approved by the County Council of Hertford.

An adjourned enquiry was held on Friday with respect to the proposed light railway or tramway in the Rhondda Fawr, from Pandy Square, near Llwynpia, to a point some distance beyond Hafod.

The Middlesex County Council have now finally approved an agreement between the North Metropolitan Tramway Company, the County Council, and the Metropolitan Tramways and Omnibus Company in relation to the construction, working, and ultimate purchase of the light railways projected or authorised under the county of Middlesex light railways joint order. The Council have decided to give notice of intention to promote a Bill in the next session to authorise them to purchase tramway undertakings in Middlesex.

The Lowestoft Council have satisfactorily settled the basis of a new agreement in regard to the East Anglian light railway order with the National Electric Traction Company.

At a recent conference of the Newry Urban District Council and the committee appointed by the Chamber of Commerce, the following resolution was arrived at: "That this meeting respectfully recommend the Urban Council to sanction the purchase of the shares of the Newry Navigation Company at £20 per share, cash, for their entire interest in the property, including assets of every nature represented therein, with the object of forming a harbour trust, and to guarantee the capital necessary to purchase such shares, said guarantee to be on the town rates, this proposal to be contingent on the procuring from the Government a loan of £150,000 at 3 per cent. for the construction of the Newry, Keady, and Tynan Light Railway."

The Commissioners recently held an enquiry into the proposed extension of Swansea tramways, at the close of which they intimated that speeches would have to be heard in London.

MANCHESTER AND ITS ELECTIVE AUDITOR.

We have before us, as published in the *Manchester City News* of Oct. 27, a long discursive address to the ratepayers of the city of Manchester by one of the elective auditors of the city, by name Mr. Norbury Williams. This gentleman poses as a most conscientious individual, and we accept him upon his own pedestal. He has, however, in a supremely irritating conscientious manner assumed what he—from the internal evidence of his own address—does not possess—namely, the ability to understand what he criticises and relentlessly condemns. Conscientious critics of the calibre of Mr. Williams are usually young—though probably in the present case it is different. Here we have a knight-errant of the type of Don Quixote, the enemy against whom he tilts being the Electricity Committee and all connected therewith. The address consists of twenty-four paragraphs. A good many sentences in some of them relate to the pains and penalties which ought to reward the wicked. Mr. Williams signed a declaration to fulfil the duties of his position "*according to the best of my judgment and ability*," as he says, and it is the awful responsibility weighing upon him under this signature that, in spite of pleadings and remonstrances, has compelled him to issue this address. We think that he has been most unfortunate in his choice of a time at which to issue his address, as it could obviously have been equally well written a month or so ago, when the chief person concerned in the charges was not the Lord Mayor-elect of the city of Manchester. We quite agree with Mr. Williams that it is his duty to expose any irregularities he finds in the working of the municipal departments, but he should be quite sure that he understands himself the grounds on which he brings any charge against a committee or its chairman. A more obvious case of an incompetent critic could not be found than paragraph 21 of the address in question. In this the Electricity Committee are accused of selling electrical energy under cost price to certain classes of consumers. We have now before us Mr. Higginbottom's reply to this absurd charge, and learn from it that, as was to be expected, the motor load at Manchester is a remunerative one. Mr. Higginbottom adds that the price of electric energy for motors was only fixed at 1¼d. per unit after having extensive reports on the subject from their engineer. These reports were open to Mr. Williams's perusal, so that he need not have made this absurd charge, which displays both ignorance and carelessness. Coming now to the connection between the chairman of the Manchester Electricity Committee and two of the large manufacturing companies which have obtained contracts for the electricity department. In spite of Mr. Williams's careful researches, he is only able to show the remote connection that certain directors of one company are co-directors with Mr. Higginbottom in an electrical undertaking which has never supplied the department with goods. In fact, a tender was once received from this third company, but its consideration was not allowed by

Digitized by Google

Mr. Higginbottom because he had a directorship on the firm. The most serious charge of all—in fact, we might say the only charge which needs consideration—was that of the cranes supplied to the gas and electricity works. It is admitted by Mr. Higginbottom that his firm were sub-contractors for certain parts of these, and it remains for the committee to look carefully into this question. It is to the interest of all that it should be most carefully enquired into, but up to the present we have heard of no evidence to the effect that the chief contractor who supplied these cranes received any preferential treatment from either of the committees. We are strong supporters of the purity of municipal life, but do not go to the absurd lengths which certain Radical organs do in this respect. If these papers had their way, it would seemingly be a dishonest act for any firm to use, say, a Nettlefold's wood screw in the fulfilment of a Government contract so long as Mr. Joseph Chamberlain or any of his blood relations owned a single share in Nettlefold's Company. As regards the charges brought by Mr. Williams against the organisation of the electricity department, one of the chief is that the engineer has had complete control of his staff, and has engaged them, increased their wages, and, we presume, discharged them without always consulting his committee. In other words, Mr. Wordingham has had autocratic control under the general supervision of his committee. If Mr. Williams had proved that the result was not satisfactory as far as the staff was concerned, or that Mr. Wordingham had allowed extras without due cause or corresponding value being received, he would have scored a point. The evidence the other way, as shown by the success of the undertaking, is so great that we are obliged to endorse the action of the committee in giving their engineer such a free hand.

FORTHCOMING EVENTS.

SATURDAY, NOV. 3.

Institution of Junior Engineers.—At 3 p.m., visit to the Millbank Station of the London Hydraulic Power Company, Millbank-street, Westminster. (Postponed from Oct. 27.)

Dundee Institute of Architecture, Science, and Art.—At Dundee Technical Institute, opening meeting. Lecture to students' section on "Some By-Ways in Architecture," by Mr. G. S. Aitken.

MONDAY, NOV. 5.

Society of Engineers.—At 7.30 p.m., at the Royal United Service Institution, Whitehall, ordinary meeting. Paper on "Notes on English and French Compound Locomotives," by Mr. C. Rous-Marten.

TUESDAY, NOV. 6.

Institution of Civil Engineers.—At 8 p.m., opening meeting of the session. Presidential address by Mr. Jas. Mansergh and distribution of awards.

Institution of Engineers and Shipbuilders in Scotland.—Graduate section meeting.

WEDNESDAY, NOV. 7.

Society of Model Engineers (Liverpool Branch).—Ordinary meeting, at Balfour Institute, Liverpool.

THURSDAY, NOV. 8.

Institution of Electrical Engineers.—At 8 p.m., opening meeting of the season. Presidential address by Prof. J. Perry, and presentation of premiums for the session 1899-1900.

FRIDAY, NOV. 9.

Faradian Club.—At 8 p.m., at St. James's Restaurant, club smoking concert.

SATURDAY, NOV. 10.

Glasgow and West of Scotland Technical College Scientific Society.—At 7.30 p.m., at Glasgow, adjourned discussion of a paper on "Slow-Speed Engine Design," by Mr. A. M. Downie.

MANCHESTER ELECTRICITY COMMITTEE.

(Continued from page 629.)

Mr. Alderman HIGGINBOTTOM's reply to Mr. Norbury Williams we have also had to condense in places. The speech in question was made before the Council on Wednesday last. It began as follows: "My Lord Mayor and Gentlemen,—I ask, as a matter of privilege, to be allowed to refer to certain allegations which appeared in the *City News* of last Saturday respecting the administration of the Electricity Committee, and allegations with reference to myself and my connection with that committee, and also in connection with numerous public companies which are supposed to be doing business with the electric department through my influence. I do not intend to make any observation upon the various items which especially concern the committee as a whole—namely, paragraphs 1 to 13—but I shall be quite prepared to deal with these matters in case a discussion upon that report arises in the Council. Nothing in that report, and nothing in the evidence given leading up to that report, made any charge or any insinuation against the engineer or officials of the Corporation or against my personal character. The committee decided upon certain new steps to be taken to make the working system and administration of a more perfect form, and some of those systems are already in operation. I would just remind the Council that the electricity undertaking has grown from a very small one to a very large one—the largest in this country—in a very short time, and it has been a most difficult task for the committee and the officials to keep pace with the demands made upon them for current, and the whole undertaking has been worked under most exceptional difficulties in supplying that demand. It is, therefore, not to be wondered at for one moment if, as happens in every large concern, certain irregularities not in conformity with Corporation precedent have arisen. I now propose to deal with the allegations against myself and my connection with the following companies as stated by Mr. Norbury Williams in paragraphs 14, 15, 16, and 20, in which reference is made to S. Z. de Ferranti, Limited; the British Insulated Wire Company, Limited; the British Electric Works Company, Limited; and the West Gorton Foundry Company, Limited. Take paragraph 14—S. Z. de Ferranti, Limited. I have no interest whatever in this company. I am not a shareholder, and no member of my family, either wife or relations, holds any shares in this company. Again, Mr. Ferranti is not a director of any company in which I have any interest. As to the work done and orders received by Ferranti, Limited, for the Corporation, to which Mr. Norbury Williams refers in paragraph 14, the following are the exact facts: At the time when meters were first ordered from Messrs. Ferranti, this firm was acknowledged to be pre-eminent in the manufacture of meters, and these instruments were the best and the most reliable for measuring the current supplied to consumers which could be obtained. Since then other meters have been perfected, and as a matter of fact no meters have been ordered from Messrs. Ferranti since October, 1897, three years ago. It is untrue to say that continuous orders have been sent this firm since 1893. The order for the two 1,000-h.p. engines and generating sets has already been fully explained by myself to the Council, and although exception was taken by several members of the Council to the order going to this firm, theirs being far the lowest offer, owing to their action during the engineers' strike or lockout, the Council fully endorsed the action of the committee in placing the order with this firm. Take the British Insulated Wire Company, Limited. I have no interest in this company, and, as far as I am aware, I have not seen a list of the shareholders. No relation of mine holds any shares in this company. Two directors of this company—Messrs. Briggs and Atherton—are co-directors of mine in the United British Electric Works Company, Limited, a company, by the way, which has never done any business with the Electricity Committee. As to the cables supplied by the British Insulated Wire Company, Limited, to the Corporation, of which Mr. Norbury Williams made such statements in paragraph 15, the following are the true facts: The total capital expenditure on mains, including the cost of laying up to June, 1900, is £359,857; the total amount paid to the British Insulated Wire Company is £44,957. The cost of laying is only a small proportion of the cost of the cables, so you can judge for yourselves as to the small proportion of orders which have gone to the British Insulated Company. But I would ask the Council to clearly understand what were the conditions under which the British Insulated Wire Company obtained their orders: (1) tenders were invited by the committee from all the principal cable makers in the country; (2) that all the tenders were carefully examined by the engineer and the committee; (3) that the British Insulated Company's tender was the lowest of five tenders for the high-tension cables which conformed to the specification of the engineer; (4) that when tenders were invited for the cables for this year's requirements, amounting to about £60,000 worth, the tender of the British Insulated Wire Company was not accepted, the prices being too high, and the orders went to five other

Digitized by Google

firms, some of whom had not previously supplied us. Where is the imputed favouritism exercised by me? Paragraph 16.—The British Electric Works Company, Limited. I am a director and chairman of this company, as stated by Mr. Norbury Williams, and, as I have stated before, two of my co-directors are Mr. Briggs and Mr. Atherton. Mr. Norbury Williams has gone very deeply into the number of shares I hold, and also into the shares held by my co-directors, and also another small holding of one of my family connections. He has, for purposes of his own, only singled out those names specially suitable for his purpose. Mr. Williams then refers in great detail to the starting of a Manchester depôt, and the engagement of Mr. Walton as its head, and imputes that it was a move of mine to enable this company to do business with the Electricity Committee. It is a shameful imputation. I have nothing to do with, and cannot be responsible for, the way in which the 'Directory of Directors' or the *Electrical Review* chooses to give paragraphs announcing the opening of depôts or the appointment of agents anywhere. The appointment of Mr. Walton came about in this way. For several months the British Electric Works Company had been seeking premises in Manchester to open a depôt, and were looking out for a suitable man to take charge of that depôt and act as agent for the whole of Lancashire. Various persons had been seen, but none were suitable. I mentioned the matter to several people who were most likely to know of a suitable man, and I was told that Mr. Walton, at the electric works, was thinking of leaving and starting in business for himself. I saw Mr. Walton, and ascertained that this was quite correct. He had reached the limit of salary to which he was entitled in the post he held, and as the engineer was not prepared to advance his salary he had told the engineer that, at an early date, he should leave the service of the Corporation. I reported these circumstances to the British Electric Works Company, and they offered him the appointment and he accepted it. But the imputation is that 'free competition is not now possible.' With whom is the competition? The electricity department do not buy electrical fittings of the type manufactured by the British Electric Company in any appreciable quantity—that is, only to fit up any office or premises in the works; and as regards consumers, all firms are upon an equal footing—that is, the Corporation electric department do not sell any fittings or electric apparatus whatever to anybody. The citizens or installation contractors who fit up the warehouses and shops with electric light buy the fittings, not from the Corporation, but from recognised makers who have submitted samples to the electricity department, and which samples have conformed to the published regulations of the Corporation. Paragraph 17.—With regard to the allegation that Corporation officials will be ready to pass the fittings of the British Electric Company, I must point out to you that these officials have no discretion whatever. There are certain fixed rules which are published and certain definite tests that all fittings have to conform to. The right is expressly reserved to any representative of a firm sending fittings to be tested to be present during such tests, and there is no room for favouritism, even though it were desired to be shown. Paragraph 19.—To say that 'Mr. Higginbottom's fittings are publicly exhibited at Dickenson-street station' is a wilful attempt to mislead. All registered fittings are exhibited at Dickenson-street, and there is a published list of those firms whose fittings have been tested and which have conformed to the Corporation requirements. There are in all 36 firms, and the total number of fittings exhibited is 407. The number of fittings exhibited that have been made by the British Electric Company is 12 out of a total of 407; 23 fittings have been submitted for registration by the British Electric Company, and of these 12 have been passed as being suitable for consumers to use, and 11 have been rejected as not conforming to the Corporation requirements. In this paragraph there is the statement that the British Electric Works Company have sent in one tender to the Electricity Committee. This was done without my knowledge. The tenders were opened by the committee and initialled, and, as usual, were passed on to the chairman to read out the prices. Upon my seeing that the British Electric Works had sent in a tender, I immediately turned to the electrical engineer, who had to examine the sketches sent in to see if they conformed to his specification, and told him that this tender must not be considered. It was not considered and not accepted. The result, therefore, is that the British Electric Works Company have not sold any goods or received any orders from the electricity department of the Manchester Corporation."

Mr. Higginbottom went on to consider the charge brought in paragraph 20, concerning the tender from the West Gorton Foundry Company, Limited. He showed that he and his family only held a small proportion of the shares in this company, and that the tender in question was one for £24 for some scrap cast iron which the electricity department had to sell. He adds that he did not know a tender was being sent in, and that he urged that it should not be accepted, but was overruled by the committee because the firm offered a higher price for the old materials than anyone else. He concludes his criticisms on paragraphs 13 to 20 by the following statement: "That I am a director in two companies—viz., the British Electric Works, Limited, and the West Gorton Foundry Company, Limited—neither of which companies has ever sold one pennyworth of goods to the electricity department, and in only the one instance of the West Gorton Foundry Company buying some old scrap metal from the department, and sold to them against my wish, and for which the Corporation received more money than any other person would pay."

Mr. Higginbottom then proceeded to criticise paragraph 21 of Mr. Williams's address, showing that the motor load was a profitable one, and that lighting consumers who burn their lamps for long hours got equally low rates. This part of his speech he concludes as follows: "The committee fixed the price at 1¼d. per unit, and they only did it after having several long reports from the engineer-in-chief, and if it has encouraged the use of motors so much the better for the electric department and the Corporation, as the current supplied to the motors is supplied at a profit. We have 500 motors at work in June, and I wish there had been 5,000, because, if so, the price for all classes of current both for lighting and power could have been reduced, and the consumer would have benefited thereby. Mr. Williams then says he finds my firm's name stands opposite 23 motors, as having fitted them up in Manchester—23 motors out of 500, three of which are in my own premises. Fitted them up, whom for? Why, for citizens of Manchester, who have asked my firm as hoist makers and who have made special study of electric hoists to put electric hoists in their premises, and of which the electric motor forms a part. What nonsense this is. My firm is to be debarred from doing business with the citizens of Manchester because I am a member of the Manchester Corporation and the chairman of the Electricity Committee. It is too absurd to consider. And out of these 23 motors my firm has not made any; they have been bought from electric motormakers—viz., other engineers.

"As to paragraphs 22 to 23—'cranes'—I have to deal with the allegation that my firm have been making cranes for the gas and electric departments. Messrs. Pearn have for years made hydraulic pumps, etc., for the gas department, and have done a very large business in hydraulic jib cranes for other firms in this county, and, as is quite common in the engineering business, made parts of these cranes themselves and sub-let other parts to other engineers—my firm amongst the number. That course was adopted in the case of the cranes referred to by Mr. Williams. Messrs. Pearn, amongst other firms, received enquiries for hydraulic cranes from the gas department. They asked my firm for tenders in the ordinary course of business. My firm tendered to them in the ordinary course. Messrs. Pearn received the order. They were then at liberty to make the cranes themselves. They called, however, upon us to make the cranes at the price we had quoted to them. We then made the cranes as we should for any ordinary customer, invoiced them to Messrs. Pearn at our contract price to them, and were paid in due course by Messrs. Pearn. The insinuation that I used the firm of Messrs. Pearn as a go-between to enable me to do business with the Corporation is too contemptible for me to take any notice of. With regard to the cranes at the electric works, Mr. Norbury Williams says: 'Mr. Higginbottom's Electricity Committee have also required cranes at their great station in Dickinson-street. Most of them have been made and erected by Mr. Higginbottom's firm. They were, of course, invoiced in other names.' Gentlemen, this is quite untrue, and again the insinuation that my firm have done business with the Corporation under the cloak of other names is entirely lacking in foundation. In no instance has my firm made a crane for the electricity department. We have made portions of them, under circumstances which I will explain. The matter is quite simple. My firm makes cranes and portions of cranes for nearly all the electric engineers in the country. If an electric crane is required for some customer in any town in this country, my firm very often receives the same enquiry from half a dozen electric engineers in the country who are tendering for this crane, leaving out the electric motors and electric apparatus on the crane, for which work they would price for themselves as the makers. If any one of these firms gets the order, and if my firm's price to them is right for the work we have quoted them for, we receive the order from them for one portion of the work. That is exactly what has happened at the electric station. The engineer reports that certain electric cranes are required. He is instructed to get out the specification for same. The committee then invite tenders from leading electric engineers in the country. Some of these electric engineers then ask my firm, amongst others, in the ordinary course of business, to quote them for certain portions of the cranes. My firm quotes them for the work asked for. They then make up their tender, including all the electric motors and electric apparatus which they make themselves, and send in their tender to the committee. If their tender is the lowest they get the order; if it is not, they do not get the order. If the lowest

Digitized by Google

tender happens to be from a firm to whom my firm has quoted for some portions of the work and my firm's price is satisfactory to them, my firm makes this portion of the work for them. My firm invoices the work done at the contract price, and is paid for it by the contracting firm, and not by the Corporation. The men erecting this work always work in the name of the contractor, and not in the name of the firm doing the sub-work. It is the usual custom, and what engineers are doing in all parts of the country to-day. My firm's business has always been carried on, and has been for 25 years, in a perfectly straightforward and honest manner, and I cannot see that we have departed from that course."

In conclusion, Mr. Higginbottom asked the Council to judge him fairly in the matter, and to say if they deemed him worthy or unworthy to take the chair. He left the matter entirely in their hands.

After considerable discussion it was decided to appoint a committee to look into the question of the allegations against Alderman Higginbottom, and to report to an adjourned meeting to be held on Monday next at half-past ten. The committee consists of the Lord Mayor, Mr. Alderman Copeland, Mr. Alderman M'Dougall, Councillors Edwyn Holt, Shann, Plummer, and Vaudrey.

CARDIFF ELECTRICITY ACCOUNTS.

From the accounts of the county borough of Cardiff electricity works just issued, it appears that the total expenditure on capital account up to March 31, 1900, amounts to £85,717. 15s. 5d. We give herewith abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc. :

REVENUE ACCOUNT.

Dr.	Generation of Electricity.	£	s.	d.
Coal or other fuel	£1,720 18 5			
Oil, waste, water, and stores	321 12 4			
Wages at generating stations	1,341 0 0			
Repairs and maintenance: buildings, £226. 2s. 5d.; engines and boilers, £235. 7s 6d.; dynames, etc., £211. 14s. 3d.	473 4 2			
Sundry and other expenses	98 1 11			
		3,954	16	10
Distribution of Electricity.				
Wages and other remuneration	121 11 7			
Repairs, etc., of mains	294 8 11			
Repairs, etc., of transformers	40 15 7			
Repairs, etc., of apparatus	80 4 9			
		537	0	10
Public Lamps.				
Attending and repairs	271 9 1			
Renewals of lamps	113 7 1			
		384	16	2
Rents, Rates, and Taxes.				
Rents payable	54 12 0			
Rates and taxes	316 1 10			
		370	13	10
Management Expenses.				
Salaries—Engineer's department	472 6 3			
Clerical staff	200 2 5			
Auditor	25 0 0			
Collector	100 0 0

GENERAL BALANCE-SHEET.

Dr.	Liabilities.	£	s.	d.
Capital account—amount received		49,324	19	11
Less premiums received with stock issues, *per contra*		885	7	5
Total debt created		48,439	12	6
Less loan instalment repaid		161	5	11
		48,278	6	7
Sundry creditors: consumers' deposits, £117. 12s.; various, £2,408. 12s. 5d.		2,526	4	5
Amount due to treasurer		37,878	7	11
Amount due to Cardiff Urban Authority account		138	4	3
Amount due to Cardiff Corporation waterworks account		54	2	4
Sinking fund		4,653	6	5
Net proceeds of law action, Corporation v. Ferranti		1,106	0	1
		£94,634	12	0

Cr.	Assets.	£	s.	d.
Capital account—amount expended for works		85,717	15	5
Deduct premiums received with stock issues, £1,031. 14s. 3d.; less expenses raising stock, £146. 6s. 10d.		885	7	5
		84,832	8	0
Stores on hand		817	7	6
Sundry debtors for current supplied		2,471	3	4
Other debtors		17	7	2
Balance at debit of net revenue account		1,647	14	10
Suspense account (renewals of arc lamps)		216	6	3
Amount due from borough fund account		125	4	5
Cash in hand of engineer		15	0	0
Investments, etc., of funds for redemption of stock		4,492	0	6
		£94,634	12	0

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T. units			673,633
Quantity sold	Public lamps	121,964	511,300
	By contract	2,744	
	Private consumers by meter	386,592	
Quantity used on works			25,838
Total quantity accounted for			537,138
Quantity not accounted for			136,495
Number of public lamps (arcs)			64
Total maximum supply demanded (kilowatts)			495

PHYSICAL SOCIETY.

At the ordinary meeting held on Oct. 26, 1900, Dr. Lodge, president, in the chair, the **Chairman** read a letter from Prof. Cleveland Abbe, of the United States Coast and Geodetic Survey, stating that the *Monthly Weather Review* would be sent regularly to any member of the Physical Society expressing a wish to receive it. On the other hand, the chief of the Weather Bureau would at any time be glad to receive communications referring to the physics of the atmosphere.

Dr. Shelford Bidwell then exhibited some "**Experiments Illustrating Phenomena of Vision.**" The first phenomenon illustrated was that known as "recurrent vision." A vacuum tube, illuminated by an induction coil, was made to rotate about a horizontal axis, and was seen to be followed at an angle of about 40deg. by a feebly luminous reproduction of itself. A spot of white light, projected upon a screen and caused to move slowly in a circular path, was also followed by a less luminous spot. The same effect was shown by spots of green and yellow light, but in the case of red light no ghost was visible. The phenomena of recurrent vision are due principally, if not entirely, to the action of violet nerve fibres. The next experiments related to the non-achromatism of the eye. The lenses of the eye do not constitute an achromatic combination, although under ordinary conditions a bright object is not surrounded by fringes of colour. The effects of chromatic aberration are disguised by the luminous haze which surrounds the object, produced by a defect in the eye regarded as an optical instrument. A six-rayed star, formed by cutting a hole in an opaque screen, was illuminated by a gauze-covered condenser containing an incandescent lamp. The star was fairly clearly defined, and there were no fringes. More attentive observation showed a luminous haze. This haze is formed in consequence of the cellular structure of the eye, and the brightest rays—orange, yellow, and green—are chiefly instrumental in forming it. If, therefore, these rays are obstructed, the conditions are more favourable for the observation of chromatic aberration. The rays were consequently cut off by means of coloured glasses, and the general hue of the star was purple. To some it appeared bordered with dark blue, while to others (long-sighted) it appeared bordered with red. Two oblong patches, one red and the other blue-violet, and of approximately the same intensity, were then produced side by side upon a screen An observer with very good eyesight was able at a distance of 10ft. to focus the patches alternately with perfect distinctness. In general, the blue patch was said to be more or less blurred. With an achromatic eye it should be possible to focus both together.

Dr. Bidwell then showed some lantern slides illustrating the complex form seen when viewing a small luminous spot through a gauze-covered lens placed so as not to be in exact focus. Some

Digitized by Google

experiments were performed illustrating the principle of the colour top. When a bright image is formed on the retina after a period of darkness it has, in general, a red border, which lasts for a fraction of a second. A dark patch suddenly formed on a bright ground has a blue border, which lasts for a similar time. These effects were attributed by Dr. Bidwell to a sympathetic action of the red nerve fibres. When the various nerve fibres occupying a limited portion of the retina are stimulated by ordinary white or yellow light, the immediately surrounding red nerve fibres are for a short period excited sympathetically, while the violet or blue and green fibres are not so excited, or in a much less degree. Again, when light is suddenly cut off from a patch in a bright field, there occurs a sympathetic insensitive reaction in the red fibres just outside the darkened patch, in virtue of which they cease for a moment to respond to the luminous stimulus. The green and violet fibres by continuing to respond uninterruptedly give rise to the sensation of a blue border. By a simple experiment it was shown that the explanation of the colour top depending upon changes in the convexity of the eye and non-achromatism, was untenable. By the use of a strong light it is possible to get negative after-images after looking at a brightly-coloured object. These images are complementary in colour to the object, and are formed even if the object is only viewed for a fraction of a second. By means of proper illumination and a disc rotating at the proper speed a red wafer was so arranged that upon looking at it it was impossible to recognise the wafer itself, but only the continuous green after-image.

The Chairman expressed his interest in the last experiment, in which it was possible to see the negative after-image of an object and not the object itself.

Prof. S. P. Thompson said these experiments threw a doubt on some of the accepted notions about the properties of the eye. Dr. Bidwell asks us to believe that the yellow haze is due to a cellular structure in the eye. Is there such a structure? Can it be observed with a microscope? And do its meshes correspond in magnitude with those necessary to produce the effects? By diminishing the size of the pupil the haze is diminished, and the sharpness of the image is increased. The effects seem to be due to ordinary aberration. Prof. Thompson said that the achromatism of the eye was simply shown by covering half the object glass of a telescope, and viewing a bright object with it. The object then seems bordered with coloured fringes.

Mr. Blakesley, referring to the colour patches used by Dr. Bidwell, pointed out that although the patches were the same distance from the lens, yet they did not possess the same magnification. The last experiment shown did away with the theory of persistence of vision, because the space between the object and the negative after-image was evidently not illuminated.

Mr. Trotter asked if red and green were the only colours which gave complementary negative after-images?

Dr. Bidwell, in reply, said the effect was obtainable throughout the length of the spectrum.

A paper "**On the Concentration at the Electrodes in a Solution, with Special Reference to the Liberation of Hydrogen by Electrolysis of a Mixture of Copper Sulphate and Sulphuric Acid**" was read by **Dr. H. J. S. Sand**. In this paper an equation has been derived for calculating the concentration at the electrode of a solution of a single salt from which the metal is being deposited, under the conditions (1) that the solution is contained in a cylindrical vessel bounded by the electrodes; (2) that no convection currents occur; and (3) that the diffusion of the salt obeys Fick's law, and its transport values are constant. This formula can be made the basis for roughly determining diffusion coefficients. In the case of mixtures it is possible to arrive at limits for the concentration, and it has been experimentally proved that hydrogen always appears at the electrode of an acid solution of copper sulphate, in which no currents of liquid are taking place between the limits of time for the concentration to go down to zero. The time which it takes for the hydrogen to appear can be calculated from an empirical formula, which is similar in form to the one used for a single salt. The great part played by convection currents in determining the ratio of the two constituents given off at the electrode of an acid copper sulphate solution has been shown by proving experimentally that artificial stirring causes hydrogen to disappear altogether in cases where it would otherwise have presented over 60 per cent. of the equivalents carrying the current from the solution to the electrode.

The Chairman drew attention to the fact that no hydrogen was liberated until all the copper had gone, and said the formula for the concentration might be used again in further investigations.

Dr. Donnan asked if the time at which hydrogen was liberated had been taken as the time at which hydrogen actually made its appearance in the form of bubbles, or whether any allowance had been made for saturation?

Dr. Sand said the time was taken up to the appearance of bubbles.

A paper by **Dr. R. A. Lehfeldt** on "**Electromotive Force and Osmotic Pressure**" was postponed until the next meeting.

The meeting then adjourned until Nov. 9.

ERROR.—With respect to the article in our last issue entitled "Some Remarks upon a Hitherto Unrecognised Planetary Law," by Mr. R. C. Shettle, M.D., line 15, second column, p. 593, the words "principle of the induction whirl machine" should read "principle of the induction electric machine."

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

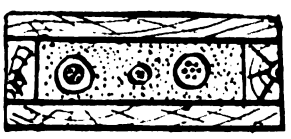
QUESTIONS.

321. Why does the temperature of the outer conductor of a concentric cable increase to nearly double the temperature of the inner when working at its full carrying capacity?—F. H.

322. Being in charge of an alternating station having a motor-alternator, I have noticed that, when this is being driven off big plant to charge cells, the excitation on big plant is considerably less (about 15 per cent.) than when it is on lighting load alone, although the motor-alternator adds about seven high-tension amperes to this lighting load. If field resistances be altered to bring excitation on big plant to normal, the machines merely drive badly. Required cause.—R. B.

ANSWERS.

Question No. 315.—I am in charge of a few miles of underground cable in this city, and I have recently experienced great trouble with them, and would like to ask whether any of your readers have had a similar experience and found the remedy. Our supply is on the three-wire continuous-current system, 220 volts between the outers; the mains are all singles, lead-covered, paper-insulated, laid in tarred sand, protected by hardwood boxing (as shown in sketch).



At every street corner we have 12 cables meeting in a box, and they are all bonded together by a copper wire soldered to the lead sheathing. At each customer's service box they are also bonded, and in many cases earthed to water-pipe or earth-plate. The lead sheathing has been badly eaten away in certain blocks, but the recent trouble has arisen in those places where the cables are good, on feeders which have no services on them, and which appear quite perfect, except just where the fault has developed and burnt a hole in the sheathing, the lead around the fault being a dark-blue colour and free from any sign of corrosion, whereas all the previous faults were in cables that were so damaged that the paper was visible in spots through the holes eaten by some chemical action. This chemical action seems to be confined to certain blocks in the city, whereas the mysterious faults have occurred in back streets where the cables have hitherto been perfect and still look perfect. It is a curious thing that all these mysterious faults have occurred since the erection of our new switchboard with its quick-break switches, and since we have used the compounding on the balancer machines. The balancers are steam-driven, and were shut down once by a reversal of the current, so they were run as shunt machines until lately. With the new board they run safely with the compound.

Best Answer to No. 315 *(awarded* 10*s.)*—The question asked by Mr. W. J. Young is not an easy one to answer, and without a complete knowledge of the facts one can but make a guess at what has happened. The first which it would be well to know is as to the tests which were made on the cable in which the faults occur. The burn out which Mr. Young describes is exceedingly like faults which are due to imperfections in the insulation, and which result in time in a short-circuit being established between the conductor and the lead. This solution seems to be somewhat improbable, as it is to be inferred from the question that the cables are not recently-laid ones, and that they have been in work for some time. The use of a quick-

Digitized by Google

break switch will have in certain cases influence on the life of a cable if there are defects in the same. It will be found, if experiments are made with a condenser, that a surging of voltage can be set up in the same by suddenly switching off a comparatively low voltage such as Mr. Young mentions. It would be interesting to try if the addition of a carbon break to the switch gear in question would have any deterrent effect on the establishment of the faults When the current is suddenly broken by a quick-break switch the actions are also dependent upon the self-induction of the machines which are rendered idle, and it is quite probable that the use of the compounding coils may have an effect as the questioner suggests. Another point which does not seem to have struck Mr. Young is that his lead-covered cables are exceedingly well earthed, owing to the way they are bonded together, and it is quite likely that they offer a much better path to lightning than other conductors in the ground. Take, for instance, an iron water-pipe. The joints between successive lengths are frequently made with materials which have not any appreciable conductivity, while the stream of water in them has also a high resistance. It is hence quite possible in certain streets where the subsoils are very dry that small discharges of lightning down the rain-water pipes, etc., will find their way into the lead covering of the cables. The result produced would be, according to the experience in other places, somewhat as described. In either case, it seems clear from the facts given that it is a discharge which causes the burn out rather than a slow electrolytic action. The writer would be inclined to ascertain if the insulation had got defective places in it by a high-voltage test with alternating currents. If some 2,000 volts were applied for an hour it would be quite sufficient to prove the uniformity of the insulation, and might localise any incipient faults which were developing.—P. T.

Answer to No. 315 (*awarded* 5*s.*).—I have known faults occurring in cables laid on the solid system, as described in the question, owing to irregularity in the compound in which the cables are placed. If the tarred sand is not properly mixed, moisture will be able to get at the lead of the cables in places, and this will cause electrolytic action, which will eat away the lead. In one town in the North of England, where tiles were laid over the compound in the wood troughing, it was found that the lead was attacked at intervals which corresponded to the gaps between successive tiles. This clearly indicated that moisture was getting down through faults in the compound to the lead. I would suggest to Mr. Young that bitumen is a much preferable protection to the lead covering than the tarred sand which has been used.—S. C.

Question No. 316.—Describe the necessaries in the construction of a multipolar continuous-current dynamo, in order to obtain sparkless commutation with a fixed position of lead for all loads.

Best Answer to No. 316 (*awarded* 10*s.*).—This point is attained fairly successfully in almost all modern multipolars by a number of small improvements in design rather than by any one definite deviation from the older machines. There have been many attempts within the last few years to find an artificial method of obtaining the result, the best known of which are the following: (1) Swinburne's method of fixing a small horseshoe magnet at the no load neutral point of the machine to produce the necessary commutating field. This magnet was series wound, so that the reversing field increased roughly in proportion to the armature current. (2) Sayer's armature winding, by means of which commutation takes place under the *trailing* horn, which is strengthened by the armature reaction, instead of under the *leading* horn, which is weakened. (3) Ryan's dynamo, in which, by means of a series winding placed in slots round the pole-faces, the armature reaction is not only neutralised, but the actual induction density at the commutating point is even increased slightly as the load on the armature increases.

The last two of these methods are used to a small extent commercially, but by far the greater number of multipolars are made to dispense with any such arrangement. In place of them, special attention is given to the following points: (1) Carbon brushes are invariably used, in spite of the considerably larger commutator required on this account. (2) The induction density in the air-gap is made large, so as to ensure a "stiff" field. (3) The tips of the leading poles, under which commutation takes place, are proportioned so as to become highly saturated under normal conditions.

Carbon brushes, by greatly increasing the contact resistance, cause the current flowing between a segment just about to leave the brush and the brush itself to fall to practically zero an appreciable length of time before contact between the two is actually broken. This effectually prevents sparking by an action more or less independent of the value of the commutating field available and of the current to be dealt with.

The advantage of a high induction density in the air-gap consists in the fact that the higher the initial (no load) density, the higher will be the minimum density with the full armature cross-magnetising ampere-turns distorting the field. Densities of 10,000 to 12,000 C.G.S lines per square centimetre are commonly used. At the same time, in order to keep the ampere-turns on the field coils down to a reasonable figure, the *length* of the air-gap must be reduced to the minimum allowed by mechanical considerations.

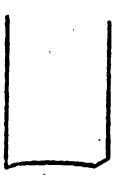


FIG. 1A.

FIG. 1B.

Saturated pole-tips are only of use in diminishing the amount by which the commutating field is altered by a given change in armature current. In the case of laminated poles, saturated tips can be readily obtained by using stampings of the shape shown in Fig. 1A, with one corner cut away, and building up the core with the stampings placed alternately one way and then the other, so that the finished core looks as in Fig. 1B. These tips have only half the sectional area of the rest of the core, and will consequently work at a considerably higher density.

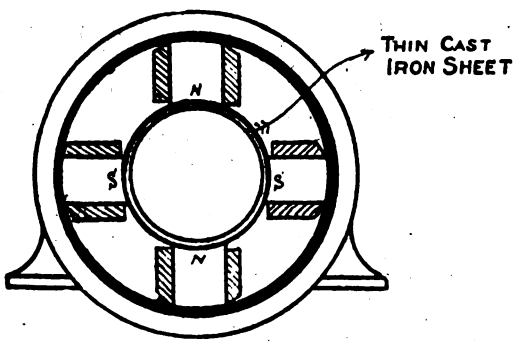

FIG. 2.

Another method is to place a thin cast-iron shell or bush in the bore of the magnets, as shown in Fig. 2. This causes some additional leakage from pole to pole, but at the same time produces a highly saturated pole-piece which is not easily weakened by armature reaction. Sometimes a deep slot is cut in the centres of the poles, as shown in Fig. 3, which has the same effect in reducing the weakening action of the armature, especially if the cores are worked at a high saturation.

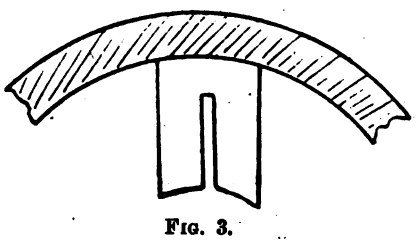

FIG. 3.

The combined effect of the above points in the construction of a machine has been found in practice to give quite successful, if not absolutely sparkless, commutation under all conditions of load and without any brush adjustment.—Q.

Digitized by Google

Answer to No. 316 (*awarded* 5s.).—A consideration of the causes naturally precedes any devising of means for the prevention of sparking. These are mainly: (*a*) That an armature coil has the direction of its current reversed during the passage of its commutator segment under the brush. There is thus an E.M.F. produced by the coil's self-inductance, tending to maintain its previous current, and opposite to that of the windings it is about to connect with the brush. Unless an equal and opposite E.M.F. is produced in it by external influence during the period of its short-circuiting under the brush, this E.M.F. of self-inductance creates a spark between the latter and the receding segment. This counter E.M.F. is usually obtained by giving the brushes lead—*i.e.*, commuting the current at such a position that the coil is under the influence of the field lines issuing from the edge of the leading pole-piece. Usually, too, since the self-induced E.M.F. is proportional to the current carried, the lead must be increased and the coil moved into a more powerful reversing field as the load increases. (*b*) Irregularity in the arrangement of the armature coils is productive of sparking. From this, however, a well-designed machine may be considered exempt. (*c*) In the case of multipolar parallel-wound armatures, inequalities in the width of air-gap, such as may be produced by not properly packing up the brasses as they wear, are apt to cause sparking. A well-constructed machine kept in good order may also be considered exempt from this.

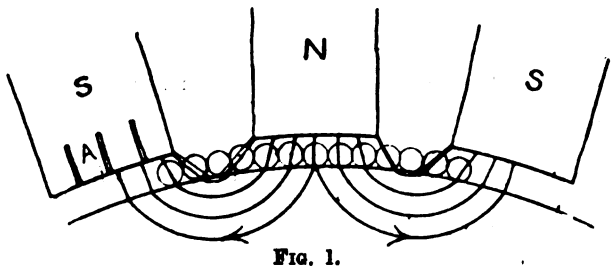

FIG. 1.

The machine under discussion is required to have constant lead and not to spark. This lead must evidently be such that at maximum load the coil is in a sufficiently strong reversing field. The question now arises as to the relation between this field (at a given point) and the armature current, also as to its effect on the coils when these carry a current less than the maximum. Dealing with the first point, Figs. 1 and 2 show the field produced by the field windings and the armature coils respectively. It is thus apparent that the armature reaction weakens the field under the leading horn of the pole-piece, and this effect is, of course, proportional to the currents flowing in the armature. If sufficient at full load, the reversing field is, therefore, from a double cause excessive at less load.

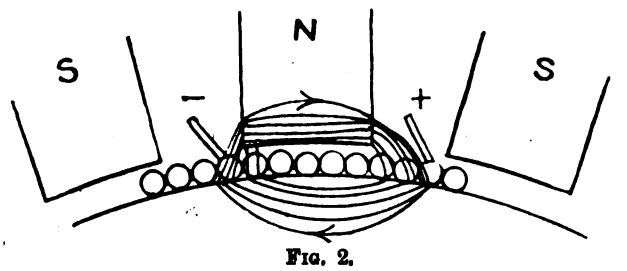

FIG. 2.

With a shunt machine the excess is more, and with a series machine it is obviously less, than with one having a fixed field excitation. The effect of this excess is that those coils which are approaching the brush enter a field of opposite sign to that of their own pole and produce some back E.M.F., thus slightly lowering the E.M.F. and output of the machine. By suitably adjusting the field distribution, it would thus be possible to make this back E.M.F. to some extent compensate for the rise of terminal E.M.F. owing to the diminished armature drop. The essentials are now deduced—viz, that armature reaction and self-inductance should be small. Hence (1) air-gap should be wide in order that the magnetic resistance to reaction lines may be great. This necessitates a field excitation strong compared with that of armature coils, and suggests a laid-on in place of a slot winding. (2) The pole-piece may advantageously be slotted, as shown at A (Fig. 1), for same reason as (1). (3) Turns per commutator segment should be few, since self-inductance varies as the square of their number. (4) Armature should be drum wound, as the inductance of internal bars is thus absent. (5) The number of poles should be as great as is consistent with the size of the machine. If there be N poles, $\frac{1}{N}$th of the total current is carried by the coil. Hence the self-induced E.M.F. is $\frac{2}{N}$ths of that in the equal bipolar machine. (6) The toe of the brush may be wide, thus allowing a longer time for the counter E.M.F. to be produced by the reversing field. Excessive width, however, would lead to undue heating.

It is assumed that the machine is parallel wound; otherwise, of course, condition 5 does not hold.—ZERO.

Answer to No. 316 (*awarded* 5*s.*). — For a machine to fulfil the above conditions it must either be one designed to work with carbon brushes or else be a machine with a special winding on the armature, such as that patented by Mr. W. B. Sayers, or some device consisting of auxiliary poles or combination of such. We shall leave out of our notice any consideration of these special devices, the majority of which are purely experimental toys, or are from a commercial point of view not altogether satisfactory. It may be as well to say that it is impossible to construct a continuous-current machine which will run sparklessly at all loads with fixed *copper brushes*, *unless* this machine be provided with some such special device as above mentioned. We propose, therefore, to consider a multipolar machine with a single winding on the armature, which is to run with fixed carbon brushes at all loads without sparking, this being a machine which is most common in modern practice.

A machine will run sparklessly if, in the commutation of a coil, the current be first brought to zero value and then raised to its exact former value in a reverse sense; at the instant of completion of this cyclical operation the coil must be on the point of leaving the brush—this is a broad statement which, of course, holds good for any type of commutating machine. In the machine to be considered this operation is brought about by the combined action of the reversing field under the leading polar horns, together with the reversing effect of the carbon brushes—this effect will be discussed later on. In order that an armature coil may be reversed by the magnetic field, it is necessary that the density of lines in the air-gap under the leading horns should be of a sufficiently high value. This may be ensured by making A T expended over the air-gap by the forward magnetism bear a relation to the distortion, A T, of the armature equal to 1·3 to 1·5. (A T = ampere-turns.)

$$\frac{\text{A T on air-gap}}{\text{Distortion A T}} = 1{\cdot}3 \text{ to } 1{\cdot}5.$$

Having now fixed a safe limit to the ampere-turns on our armature relative to the ampere-turns expended on the air-gap, we may now discuss the winding of the armature. It is essential that in an armature winding the reactance voltage per section when undergoing commutation should be kept low, as this is the chief or primary cause of sparking—neglecting the resistance of a section. Reactance volts per second = $2\pi \times \frown\!\!\!\sim \times M \times C$. $\frown\!\!\!\sim$ = cycles per second or periodicity of commutation; M = mutual + self-induction of short-circuited coil measured in henrys; C = current in coil.

The periodicity may be taken as the reciprocal of twice the time taken for one section to pass under the brush, so that the governing factors for the periodicity are: peripheral speed of commutator, width of commutator section, and thickness of brush. All these should be so proportioned as to keep the periodicity low. Mutual and self-induction of short-circuited coil should be kept as low as possible. Self-induction may be reduced by proper designing of slots—*i.e*, wide slots—and keeping the turns per armature section down to a minimum. Mutual induction may be kept low by distributing the sections or turns in the armature slots so that no sections or coils lying in the same slots are undergoing commutation at the same time. The current

Digitized by Google

per coil should be minimised, having due regard to manufacture from a commercial point of view, by making use of a multiplex winding—as, for example, by making use of a multiplex series-wound multipolar armature, or else a multiplex parallel-wound multipolar armature. This has the effect, not only of reducing the reactance volts per coil, but prevents a quivering of the main magnetic field due to armature reaction.

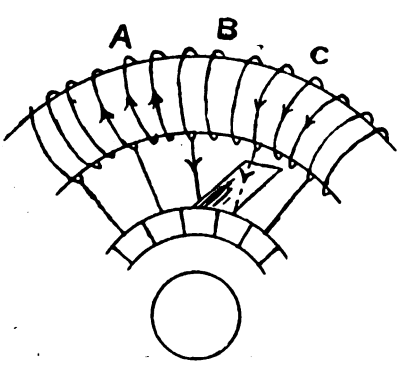
By bearing in mind the above points in design, we find that the reactance volts per coil commutated may be as low as one to two volts. This figure enables us to fix the lead of our brushes, and any alteration in the reversing field under the leading pole-tips due to the variation in the loading of the machine, is compensated for by the virtue possessed by carbon brushes in setting up a difference of potential between the leading and trailing tips of the brushes. This difference of potential is caused by the varying current density at the brush face as a coil is commutated, producing a difference in the C R drop between the leading and trailing tip. C = current in brush, R = resistance of surface contact of brush.

It may be remarked that in small machines, say up to 8 kw., it is commercially possible to construct them with so small a reactance volts per section as to enable the commutation to be brought about entirely by the action of the carbon brush, and without any assistance from the reversing field under the leading polar horns. We might amplify all the above points by *actual* design, but feel that we cannot go any further into the matter of commutating machine, as we have already trespassed too much on your space and time.—H. P.

Answer to No. 316 (*awarded* 5*s.*).—The chief cause of sparking at the brushes of dynamo-electric machines is due to the shifting of the plane of commutation when the load, and consequently the amount of the armature reaction, varies. By employing relatively strong field magnets the distortion of the field is greatly diminished, and remains more constant.

The cross-magnetising effect of the armature may be reduced by such devices as slotting the pole-pieces in a direction parallel to the shaft; shaping the pole-tips so that they may be saturated by a weak field, and are therefore of a low permeability; or increasing the air-space between the armature and the pole-pieces, thereby increasing the reluctance of the path of the lines of force due to the current in the armature. The last-mentioned method, although extensively used, possesses the disadvantage that the reluctance of the useful magnetic circuit is also increased, requiring additional ampere-turns in the field windings, and thus losing one of the gains of the use of embedded armature conductors.

Having now got a fixed field, let us observe what takes place in a coil at the moment of commutation. In the diagram the current from one-half of the armature is



flowing round A to the brush, and from the other half round C in the opposite direction. It is evident, then, that the current in B must be stopped and started again to an equal value in the opposite direction before the commutator bar leaves the brush, else sparking will ensue. The self-induction of the coil retards this stoppage and reversal, so that the coil, short-circuited by the brush, is really not idle, but is cutting lines of force and generating an E M.F. which just counteracts that of the self-induction. Attention must be directed to the shape of the pole-tips in order to produce a fairly uniform field through the short-circuited coils of correct intensity to promote this reversal of the current in them. Then the self-induction is lessened by using few turns per coil. The shape of the armature teeth also determines, to a certain extent, the value of the self-inductive effect, as was explained in the answer to Question No. 274. A multipolar machine, without cross-connections in the commutator, permits of the commutation of the current being done in detail, which is advantageous, especially when large currents are dealt with. By inserting resistance in series with the short-circuited coils it is made possible to cover three or four commutator segments with the brush, thus allowing of small variations of the plane of commutation without the attendant sparking. The use of German-silver wires for connecting the coils to the commutator bars accomplishes this, or, as is now almost universally adopted, the substitution of carbon for copper brushes.

Again, if the teeth of the armature core are too far apart, the lines of force are gathered into them in "tufts," and vicious sparking is caused as the teeth approach and recede from the pole-tips. This is eliminated when the teeth are close together and cover a large part of the armature surface, or if the armature is wound over with iron wire. One form given to pole-tips consists of a thin cast-iron ring joining the pole-pieces, which answers the same purpose.—J. D. S.

TUNBRIDGE WELLS ELECTRICITY WORKS.

The following is an abstract of the report of the borough electrical engineer of Tunbridge Wells on the fourth completed year's working of the electricity undertaking:

I have the honour to present my annual report on the fourth completed year's working of the electricity undertaking in the borough. In this year's report I propose dealing chiefly with a description of the extensions we are undertaking, which extensions will enable us to supply an additional 24,000 8-c.p. lamps connected to the mains. These extensions were recommended to you in January, 1899, but owing to various circumstances they were not undertaken until February, 1900, and are now well on the way to completion.

Buildings.—The buildings which are now in progress will add another 52ft. in length by 78ft. in width to our present works, and comprise a boiler and engine house. In order to make room for these it has been necessary to take away a portion of the existing stables. In the engine-house there is room for accommodating another three engines, which can be ordered as required. In the boiler-house I have made provision for four Lancashire boilers, which necessitates the building being wider than would be the case if tubular boilers were employed, so that the buildings, when full of machinery, will be large enough to supply 94,200 8-c.p. lamps; and at the present rate of increase this would take 12 years before it will be necessary to again extend the buildings. I have arranged openings in such a position that the minimum amount of labour is entailed in handling the fuel used, coupled with great rapidity of discharge, as there has been difficulty in unloading coal hitherto.

Boiler House.—There are five Babcock and Wilcox boilers now working, each capable of evaporating 4,000lb. of water per hour. These boilers are being supplemented with two Lancashire boilers, 8ft. 6in. diameter by 30ft. long, each boiler being capable of evaporating 8,000lb. of water per hour, and working at a pressure of 160lb. to the square inch. To make room for these new boilers, I have designed an underground flue, which will connect with our present flue, and with the new shaft when built. The boilers are being provided with the best-known fittings in the market, including superheaters in order to gain every possible economy in coal consumption and working cost. The steam is delivered from these boilers to the superheaters, and then through the main steam ring to the engines. Superheaters are not in general use, but are becoming so in all the modern works. The boilers, main flue, foundations, etc., are costing us £3,295. 15s. 2d. A new feed pump is being installed capable of delivering 5,000 gallons of water per hour against a pressure of 160lb. The condensing plant will be between the old and new boilers, consisting of air and circulating pumps, capable of dealing with 30,000lb. of steam exhausted from the engines per hour, returning the condensing steam to a storage tank called the "hot well." A grease separator is provided for extracting the grease from the steam. This is inserted in the main steam exhaust pipe in a suitable position. On the feed service a well-known filter of the "Edmiston" type is placed, so that we should have no trouble with oil or grease getting into the boilers, having thus taken double precautions. The condenser itself consists of a number of brass tubes, exposing a cooling surface of 3,000 square feet. There are two 14in. mains connecting the condenser with the cooling tower. When the condenser, the hot-well, the pumps, and all the requisite machinery for converting the steam into water are completed, the plant will be second to none in the

Digitized by Google

kingdom, as everything is specified to be of the most approved pattern. The condensing part of the scheme, with the cooling tower, pumps, engines, piping, foundations, etc., will cost £5,221.

Water Reservoir.—In connection with the condensing scheme, we have built a large water reservoir, capable of holding 100,963 gallons of water. In the construction of this reservoir over 600 tons of concrete have been used. The reservoir forms the foundations for the cooling tower, which cooling tower is 60ft. high, and capable of dealing with the heated circulating water when cooling 30,000lb. of steam per hour. At present this is the largest tower erected of its sort south of the Thames, and will be of material value to us in providing a good supply of fresh water, which has been well exposed to the air continually, as well as heated and cooled many times, so that the cooling tower and the reservoir form (1) a large storage tank for water, (2) a means of cooling the circulating water after leaving the condenser, (3) a water purifier. These cooling towers, where there is an insufficient supply of water for condensing purposes, are becoming general.

Engine-Room.—In the engine-room we are putting down a 400-kw. Willans-Ferranti set, which will bring the capacity of our plant up to 1,070 kw. This set, together with the foundations, will cost £4,553. 14s. 8d.

Switchboard.—A switchboard of the latest approved type for controlling high-pressure electricity supply is being provided, and will be situated in the corner of the engine-room now occupied by the rectifiers, which rectifiers will be removed to the new buildings. The switchboard provides controlling gear for the alternators, and has a capacity of 400 kw. It will cost £780. 10s.

Distribution Department.—Mains have been laid in all the important streets of the borough, the aggregate length of the cables being 40 miles. We have continued our policy of doing away with the small house transformers, and connecting the consumers to the 220-volt network. During the year we have only been troubled with damage to one of the cables, which was done when the road was opened up for the purpose of laying a water supply. The mains have been kept in perfect repair, and, so far as one can ascertain by testing, they are as perfect to-day as when first laid.

Shaft.—In future extensions I have always contemplated building another shaft at the opposite end to the present one, and for this purpose the main flue has been extended right along the whole length of the building, not because we require a new shaft at present, but we shall do so in the near future, and I note with satisfaction that Sir William Preece confirms my original idea, as there is considerable difference in opinion as to the capacity of a shaft; the American practice being twice what the English practice is, and in America our present shafts would be considered ample for years to come provided the draught were not affected, whereas in England it would now be considered sufficiently loaded.

Nuisances.—During the year we have been troubled, and somewhat severely handled, by complaints with respect to smoke and vibration, and I would respectfully inform you that the extensions to the works, suggested in my report presented to you on Jan. 4, 1899 (18 months ago), should remedy all reasonable causes for complaint. With regard to the smoke nuisance, the new extensions which you decided to carry out in January, 1900, and for which contracts have been entered into with Messrs. Tinkers, the boilers are designed in such a manner, and with smoke-consuming devices, which should obviate most of the difficulty, as I think you are now aware that the cause of the trouble is brought about by (1) the inferior quality of the fuel supplied by the contractors (for which we obtained damages); (2) on account of the particular type of boilers we were using, and the fact that these boilers were hard pressed, so that it was only possible to burn certain classes of fuel in order to hold steam. The new ones will provide ample boiler power, and will be equal to an addition of four of the old type. The new type of boiler is not a "smoke producer," and can be worked more easily with a minimum amount of smoke, especially as it is fitted with smoke-consuming arrangements.

Bad Water.—I have during the year had 10 analyses made of the Jackwood Springs and the town water for steam-raising purposes. The experts have given me as their opinion that it is not amenable to treatment, and below is a copy of the report I presented to the committee with reference to our water supply. I have carefully studied the question of the purification of our well water, based upon our following analysis:

Well Water.	Grains per gallon.
Calcium carbonate	·70
Calcium sulphate	7·43
Sodium chloride	5 61
Oxide of iron	·81
Nitrates and nitrites of lime and magnesia	3·95
Total	18 50

The well water is not a good one for boiler purposes. It contains a considerable quantity of mineral matter in solution, and if not treated before going into the boiler it will cause the formation of a very hard scale on the plates and tubes. It has also corrosive properties, due probably to the nitrites and nitrates, and possibly to the chlorides. Although there is no free acid in the water, the reactions which take place at the high temperatures which are attained in our boilers probably give the water acid properties, and there being nothing in the water to neutralise these they attack the metals with which they are in contact. The scale-forming impurities could be removed by the addition of good soda ash before the water is used in the boiler, but we should require settling tanks for this purpose. If you continue to use the well water I should advise you to adopt this course, as a little soda ash would make the water alkaline to a certain extent, and would tend to mitigate the corrosive action. It will be seen from the above analysis that the presence of nitrates and chlorides in the water tend to indicate that it is polluted by sewage or other impure water draining into the well, or percolating through the soil. Unfortunately, the samples of well water differ, showing that the character varies from time to time. The analysis of the town's water is as follows:

	Grains per gallon.
Calcium carbonate	1·75
Calcium sulphate	·53
Magnesium sulphate	·72
Magnesium nitrate	·90
Sodium chloride	2·64
Total	6·54

The following is a copy of an analysis made by Mr. Kent Smith:

Soap Test.	
Temporary hardness	Nil.
Permanent hardness	11 80
Total hardness	11·80

Alkalinity equivalent, ·35 grain calcium carbonate per gallon.

Residue.	Grains per gallon.
Calcium carbonate	·13
Calcium sulphate	5 90
Magnesium carbonate	trace
Magnesium sulphate	nil.
Magnesium chloride	·93
Sodium chloride	4 95
Alumina, etc. (soluble)	2 73
Silica	·15

Sample of scale: Mark, Tunbridge Wells (one piece only received).

Result of Analysis.	Per cent.
Calcium sulphate	91 20
Calcium carbonate	·54
Magnesia	2·70
Alumina and peroxide of iron	·80
Insoluble siliceous matter	2·48
Combined water and organic matter	1·84
	99·56

The following is a copy of an analysis made by Mr. Cecil H. Cribb:

	Grains per gallon.
Total solid residue	31·15
Chloride	3·71
Chloride of sodium (calculated)	—
Nitrogen as nitrates and nitrites	—
Nitrate of soda (calculated)	—
Temporary hardness	none
Carbonate of lime (calculated)	—
Permanent hardness	19·0
Sulphate of lime (calculated)	25·8
Total hardness	19 0
Remarks—free carbolic acid	9·0

The sample is quite devoid of free non-volatile acid, being slightly alkaline after boiling.

I have also been in communication with Mr. Dewrance, with Mr. Hiller (of the Boiler Insurance Company), Captain Sankey, and several others, all of whom admit it is a very difficult water to treat. One of the most successful treatments for the purification of water is known as the "Archbutt-Deeley" process, by which the carbonate of lime, or calcium carbonate, can be got rid of, and the hardness reduced from anything to about 4 per cent. Unfortunately, it will be noticed that in our water the carbonates are low, the sulphates predominating. Calcium sulphate is one of the most objectionable constituents of boiler water on account of the hard scale it produces. I am of the opinion that sulphate of magnesia is formed, as carbonate of lime, when boiled with sulphate of magnesia is transformed into sulphate of lime, and, when the temperature is high enough, changes into hydrate of magnesia, the chemical change forming a hard scale like porcelain, similar to that which we had in our boilers. An excellent paper was read by Mr. Leonard Archbutt before the Institution of Mechanical Engineers, on the subject of "The Softening of Water," in which he showed clearly that certain classes of water do not render themselves amenable to treatment, and in many cases the source has to be given up and a fresh one sought after. I, therefore, think it is advisable for the committee to wait and see the effects of the condensing plant, as I have designed it in such a manner that we use the water over and over again, adding about 12 per cent. as make up, which 12 per cent. I propose taking from the discharge side of the condenser, and this water, after having been cooled, softened, and heated many times, should be fairly pure. We have tried both town and Jackwood Spring water for this purpose, and do not find that by using the town water the result is any better than the Jackwood Springs for steam-raising purposes, and taking into consideration the expense of using the town water as compared with the Jackwood spring water, the advantage is strongly in favour of using the latter. I have given a great deal of attention to this subject and the correspondence, reports, etc., would fill a small book, and I have fully appreciated the fact that it is our most serious trouble, and for that reason I may say that the new plant when erected should remove most of this, as we shall be using distilled water, with the exception of about 12 per cent. make-up, which will be purified and treated, so that the difficulties with the corrosive action in the tubes and

Digitized by Google

deposit may be removed. This will effect a saving to us of at least £300 per year in repairs.

Financial.—Referring to the revenue account, the profit for the year available for dividend if the undertaking were owned by a company is £3 120, as against £3 984 for the previous year, and after paying the interest and redemption fund on the borrowed capital there remains a net profit of £764. Comparing the gross profits with the previous year the sum is less by £864, which is attributable to the large reduction in the prices charged for electricity in the borough both for private and public lighting; the average price obtained from private consumers being 4·8d. per unit, and for public lighting 1·19d. per unit, which price for public lighting is lower than any other town in the kingdom. The previous year the average price charged to private consumers worked out at 5 68d. per unit, or nearly 1d. more, and the average price obtained for public lighting was 2 93d. per unit, or 1¾d. more per unit This means that the private consumers have been getting their electricity at nearly 25 per cent. reduction, and the public lighting (the general district rate) have been supplied at a reduction of 140 per cent. It is not surprising, therefore, that the profits should be considerably reduced. It is interesting to note the relative prices obtained from various classes of consumers in Tunbridge Wells: public houses and hotels, average price paid for electricity per unit, 3 9d.; shops, 4·8d.; private houses, 4 89d.; offices (early closing), 6 00d.; churches, 6·00d.; from which it will be seen that public-houses and hotels obtain their supply at an exceedingly low rate, and far cheaper than they could ever hope to generate it for themselves. The fuel works out at an increase of ·22d. per unit. The stoker's bonus system has worked well during the year, and tends to reduce the amount of smoke emitted from the shaft. In the other items, which comprise the works costs, it will be seen that they have been reduced, although not so much as I should like. If we had not reduced the price, our net profits this year would have been £3,130. It will be seen from the income side of the account that the wages, repairs, carbons, and interest on the capital, which may be properly debited to public lighting, amount to a large proportion of the total revenue obtained for public lighting, and, of course, this sum must be deducted from the total revenue for public lighting in order to ascertain the true price charged per unit, as it then places public lighting on the same basis as a private consumer, which consumer has to wire his house and supply his fittings at his own expense.

Mr. Boot also gives a table, showing the progress of the undertaking, and states that so far as the costs go, and owing to unfavourable circumstance, he has been unable to show a decrease in the total costs. However, this was general with all undertakings, and was caused by the increased price of fuel. A table is then given showing the works costs at neighbouring towns, and it is interesting to note that Tunbridge Wells comes fifth, the cost per unit sold being 1·63d. and the number of units sold 496,297. The dividend on stock and redemption fund are responsible for £2,355, which is equal to 1·13d. per unit, from which it will be seen that the capital outlay bears very important relationship to the success of the undertaking.

ANALYSIS OF COSTS SHOWING PROGRESS.

—	1899-1900.			Cost per unit.	1898 9. (approx.)	Cost per unit.
Coal and other fuel	£2,445	12	9	1·18d.	£1,350	·96d.
Oil, water, waste, and stores	170	12	0	·07d.	109	·07d.
Wages of workmen	566	13	9	·27d.	511	·357d.
Repairs and maintenance	196	7	0	09d.	112	·07d.
Works costs	3,379	5	6	1 63d.	2,082	1·48d.
General costs—						
Rents, rates, and taxes	299	12	9	·14d.	213	·152d.
Management expenses	1,163	5	4	·557d.	899	·643d.
Total costs	£4 842	3	7	2·327d.	£3,194	2·275d.

STATEMENT OF ELECTRICITY GENERATED AND SOLD.

Quantity generated in B.T. units			620,558
Quantity sold	Public lamps	164,924	496,297
	Consumers by meter	332,273	
Total maximum supply demanded (kilowatts)			423

Number of lamps, 28,502 (66 arcs).

The statement of electricity generated and sold is satisfactory. The number of lamps connected has gone up considerably, the maximum supply demanded has increased from 306 kw. to 423 kw., or an additional 200 h.p., and we now have as many lamps connected to the mains as we have inhabitants, which is a record result.

Net Profit.—Adding our net profit for this year to the balance brought forward from last year (after giving last year 1d. to the general district rate), there remains a surplus to date of £2,039 for the Council to deal with, and I would recommend that £1,000 of this amount be put to the reserve fund, the remaining £1,039 being carried forward to next year's account. I regret that I cannot recommend the Council to further reduce the price of electricity, but hope at some future date, when the price of coal and other materials have gone down to their normal, that I shall again be able to recommend a further reduction, as I believe a "cheap and efficient supply" is the correct motto for a successful electricity works. We have sold more than 40 per cent. of our total units to private consumers at 3d, the figures being 125,007 at 3d. and 207,266 at 6d. A table is given showing a comparison of the average price obtained for private and public lighting in similar towns, Tunbridge Wells coming about second in the list.

Public Lighting.—The Council have during the year decided to light 262 additional electric incandescent lamps. This will mean that the borough will be lighted by arc and electric incandescent lamps, with the exception of the outlying streets, where no cables are laid.

As to workmen's dwellings, it is suggested that if the Council decide to build houses for the working classes they should instal the electric light, as they could well afford to supply workmen's dwellings at 10s. per 8-c.p. lamp per annum. The lamps would remain the property of the Corporation. Free wiring was quite as necessary to-day as ever, and there was a future before a firm who would work the business on sound commercial principles and give satisfaction. Many householders who let apartments appeared to have appreciated the value of electricity as an illuminant, and many of them have had the electric light installed. As to the supply of lamps, owing to many complaints due to faulty lamps, Mr. Boot thinks it would be in the interests of the undertaking to supply lamps to the consumers of a well-known make at cost price plus a small additional sum to cover expenses. When the new works are finished there will be room to accommodate over 2,000 kw., or sufficient plant to supply 120,000 8-c.p. lamps connected. At present, however, only orders for plant to the extent of 1,170 kw. are being placed. He also considers it advisable to extend their lighting area, as they could supply neighbouring towns and villages at a much lower rate than they could afford to if they established their own works He would recommend the Council to purchase motors and heating apparatus, and to let them out on hire to the consumers. This has been done with considerable success in many of the large towns, and he thinks there would certainly be a market and demand for same in this town.

Mr. Boot then says: "Before concluding, I desire to thank the chairman and members of the committee, who have given most valuable time to the town in the interests of the undertaking, as well as the staff employed, for their loyal services, and the officials belonging to the other departments for their kind assistance."

Appended to the above report is a copy of the report presented to the Electricity Committee, in which Mr. Boot sets forth the advantages of electric tramways. For Tunbridge Wells, it may be remembered, he recommends the use of the overhead trolley system, and gives the routes along which the tramways might run. The best route, and the route which would be of most service to

Digitized by Google

the inhabitants of the town, would, he thinks, be from the Brighton Railway Station *vid* Montacute-road, Eridge road, London-road, High-street, Mount-pleasant, Grosvenor-road, St. John's, London-road (Southborough), the total distance being three miles. The narrowest point on this route is 25ft., and the heaviest gradient 1 in 9, which, however, is short. The sharpest radius is at the bottom of High-street, being 11ft. The length of the alternative routes is about the same; the narrowest point being on one of 24ft. The heaviest gradient is 1 in 15. On the other the heaviest gradient is 1 in 9.

A rough estimate by the author as to the cost of construction is as follows:

Track construction, including by-passes	£15 000
Overhead construction	5,400
Six cars	3,600
Car-shed	7,000
Sundries, say	2,000
Total cost of equipment	£33,000

It would, of course, be necessary to add to the machinery at the works, but this would not be very expensive, as the load factor on a tramway system is high. As to the working expenses, he puts it at 8d. per car mile, on account of the hills. The number of car miles estimated to be run in 313 days, working 10 hours per day, with four cars on the route, was 75,120 car miles. Thus the cost per annum equalled £2,504; interest and sinking fund on the capital expenditure, at 6 per cent., equals £1,980—making a total of £4 484 per annum. Each car could carry 44 passengers when taking about 44 kw. Each car would be equipped with two 25-h.p. motors geared to the axles, and the current supplied to the motors would be controlled by the motorman through a series-parallel controller.

LEGAL INTELLIGENCE.

COVENTRY GASFITTING, ELECTRICAL, AND ENGINEERING COMPANY.

In the Companies' Winding-up Court, on the 25th ult., Mr. Justice Wright heard the petition of A. Davies and another for the winding-up of the Coventry Gasfitting, Electrical, and Engineering Company, Limited.

Counsel said since the presentation of the petition a scheme for reconstruction had been laid before a meeting of the company, and a resolution had been passed by the directors asking that the petition should be allowed to stand over for six weeks.

Mr. Buckmaster, representing two creditors, said his clients knew nothing of the scheme, which should be laid before them in a formal and proper way. He suggested that there should be an adjournment for a fortnight.

His Lordship adjourned the petition for six weeks, with liberty to restore it to the list within that period if necessary.

LONDON ELECTRICAL CABS.

In the Companies' Winding-up Court on the 31st ult. Mr. Justice Wright gave his reserved judgment in the matter of the petition of Colonel C. E. Foster and others for the compulsory winding-up of the London Electrical Cab Company, Limited.

The directors opposed the petition on the ground that compulsory winding-up would render valueless their only remaining assets, which consisted of two licenses.

Mr. Counsel, for the petitioners, said all personal charges against the directors had been withdrawn.

Mr. Justice Wright said the interests of the shareholders ought to be protected so far as the licenses were concerned, and the business of the Company ought not to be terminated. The alleged secret agreements had not been supported by evidence, and he was willing to appoint a provisional liquidator if asked to do so.

The matter was allowed to stand over until next Wednesday.

RECORDING TELEGRAPH, LIMITED.

Mr. Justice Wright also heard a winding-up petition of this company this week. It was mentioned that the company's assets consisted of shares in another company, which it was expected would become more valuable in a short time. The petition was ordered to stand over so that evidence might be filed.

REFUSE DESTRUCTION.

On Tuesday, at Lambeth, the South London Electric Supply Company were prosecuted for causing a nuisance by burning refuse at their works at Loughborough Junction. The company are by contract with the Vestry compelled to take over the refuse and destroy it.

The case was adjourned on the undertaking that no more refuse would be burnt.

FIXING UP A TELEPHONE.

Mr. H. E. Childs, Liverpool-road, Islington, sued Messrs. Charles Atkins and Nisbet, 1, Water-lane, in the City of London Court last week, for £3. 3s. for fixing up a telephone at their premises. The defendants paid £2. 10s. into court, and said they thought that was more than the plaintiff was entitled to—an incompetent workman had been sent in the first place, and the work might have been done by an ordinary bellhanger. The plaintiff said his charges were quite reasonable. The learned Commissioner pointed out that the defendants had not made any bargain as to price. A jury would have to decide what was reasonable under the circumstances. The plaintiff must summon a jury within three days, or be non-suited.

COMPANIES' MEETINGS AND REPORTS.

ST. HELENS CABLE.

This Company held their first annual meeting on Oct. 21 at St. Helens.

Mr. Heyl-Dia, taking the chair, proceeded to report on the progress of the past 13 months, which was so satisfactory that although the Warrington electric cable works had only been working for the past six months, the Board were in the pleasant position of being able to recommend that a dividend of 6 per cent. on the ordinary shares be declared and paid forthwith. The prospects of the Company were as bright as could be wished, as the works were going night and day, and the continued addition of new plant was being fully occupied as it was put down.

The report was adopted unanimously, with the usual amenities amenities attending the conclusion of a satisfactory meeting.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH.

The directors, in their report for the half year ended June 30 last, state that two quarterly dividends of 1½ per cent. each have been paid, leaving £116,953, from which £120 has been deducted for dividend on new shares, and £100,000 transferred to the general reserve fund, leaving the balance of £16,833 to be carried forward. The gross receipts amounted during that period to £313,227, against £324,361 for the corresponding half-year of 1699. The working expenses, including £28,261 for maintenance of cables, absorb £108,660, against £107,267 for the corresponding period of 1899, leaving £204,567. During the half-year the unissued balance of 50,000 shares of the Company's share capital was issued to the shareholders at a premium of £3 per share, or £13 each, and an official quotation has been obtained. The balance of 5 per cent. Australian Government subsidy debentures has been paid off.

CAPE ELECTRIC TRAMWAYS.

The report of the directors for the year ended June 30, to be presented at the meeting to be held in London on 14th inst., shows a net balance to credit of £65,204, which added to £15,615 brought forward, makes a total available of £80,820. The directors have already paid two interim dividends amounting to 9 per cent. upon the capital. The directors have also placed £8,000 to the credit of the reserve fund, and have created a special reserve to the credit of which they have placed £12,000. The directors recommend a bonus of 3 per cent. upon the capital, which will absorb £12,000, leaving £12,820 to be carried forward. During the 12 months' working the Cape Town system has carried 11,332,627 passengers, as against 8,489,490 passengers in the preceding year. The Port Elizabeth system has carried 2,967,420 passengers, as against 2,563,259 passengers in the preceding year. The grand total of passengers carried on both systems for the preceding year was 11,052,749. For the year under review the total number is 14,300,047, which shows an increase of 3,247,298.

WESTERN TELEGRAPH.

The ordinary general meeting of the Western Telegraph Company, Limited, was held on the 30th ult. at Winchester House, E.C. Mr. W. S. Andrews presided. The report and accounts, already noted by us, were passed.

The **Chairman** said the joint working of the two companies had proved to be more advantageous than the separate workings had been.

A final dividend of 3s. per share (making 6 per cent. for the year) and a bonus of 2s. per share was declared.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Midland Railway Company.—Particulars of contracts for stores, 1901, will be found in our advertisement columns. Tenders close Nov. 13.

Kendal.—The Corporation invite tenders for the supply and erection of various plant. Tenders by Dec. 1. Details in our advertisement columns.

Farnworth.—The Urban District Council invite tenders for the wiring of premises on a deferred payment system. Tenders by Nov. 12. Details in our advertisement columns.

Newcastle-upon-Tyne.—The New Tramways Committee of the Corporation invite tenders for arc lamps and accessories. Tenders by 21st inst. Details in our advertisement columns.

Digitized by Google

Pemberton.—The Council invite tenders for boilers (preferably Lancashire), engines and dynamos, battery, switchboard, crane, and conductors. Tenders by Nov. 8. Details in our advertisement columns.

Nottingham.—Tenders are invited for the installation of an electric lighting plant at the new workhouse. Specifications may be obtained from Mr. G. Muncaster Howard, clerk, Poor-Law Offices, Nottingham.

Grantown-on-Spey.—The Commissioners of the burgh invite tenders from electric light companies to supply electric light for public and private consumption within the burgh. Tenders by Nov. 6. Details in our advertisement columns.

Wolverhampton.—The Tramways Committee invite tenders for erection of car depôt, paint and repair shops, etc., at Cleveland-road. Plans, etc., may be seen at the office of Mr. J. W. Bradley, C.E., M.I.M.E., borough engineer, Wolverhampton. Tenders by Nov. 19.

Glasgow.—The Executive Committee invite tenders for the wiring for arc and incandescent lighting and electric motors at the Glasgow International Exhibition, 1901. Full particulars can be had on application to Mr. Thomas Young, the engineer, 4, West Regent-street, Glasgow.

Manchester.—The Tramways Committee invite tenders for the supply of cast-iron bases for tramway poles. Specifications, etc., may be obtained on application to Mr. J. M. M'Elroy, general manager, Tramways Department, Town Hall, Manchester. Tenders by Nov. 9. Details in our advertisement columns.

Walker (Northumberland).—The Urban District Council invite tenders for the erection, complete, exclusive of buildings, of a two-unit dust destructor of the Meldrum type, etc. Specifications can be obtained from the engineers, Messrs. Handcock and Dykes, 1, Victoria-street, Westminster, London, S.W. Tenders by Nov. 13.

Harwich.—Tenders are invited for gas-engines, dynamos, cables, battery of accumulators, combined lighting and traction switchboard, street boxes, corrugated iron buildings, engine and dynamo foundations, double-decked cars, track laying, and traction equipment. Tenders by Nov. 17. Details in our advertisement columns.

Leeds.—The Leeds Tradesmen's Benevolent Institute invite tenders for the installation of electric light required in alterations and additions to 41, Park-square, together with three shops and business premises, Park-lane, Leeds. Plans, etc., can be obtained from Messrs. Butler, Wilson, and Oglesby, architects, 12, East-parade, Leeds.

London (City).—The Streets Committee of the Corporation invite tenders for the hiring of a mechanically-driven dust-cart for collecting and removing the dust, trade refuse, and street sweepings from the City to the Corporation's depôt at Lett's Wharf, Commercial-road, Lambeth, S.E. Tenders by Nov. 10. Details in our advertisement columns.

Stockport.—The Tramways Committee invite tenders for the overhead equipment and supply of rail bonds for six sections of their electric tramways, having a total length of about 2 miles 3 furlongs 5 chains double line, and 2 miles 2 furlongs single line. Specifications, etc., may be obtained from Mr. A. J. H. Carter, electrical engineer, or Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Stockport.—The Tramways Committee invite tenders for the laying of the permanent way of their electric tramways, including concrete foundation, but excluding bonding and paving, in six sections, having a total length of about 2 miles 3 furlongs 5 chains double line, and 2 miles 2 furlongs single line. Plans, etc., may be obtained on application to Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

London, S.W.—The London County Council invite tenders for the supply, within 10 weeks of the order being given, of about 150 arc lamps, required in connection with the electric light installation for the Victoria-embankment and Westminster Bridge. Approximately, 80 of the lamps will be for current of 10 to 12 amperes, and 70 for current of 5 to 6 amperes. The lamps will be run in both cases 10 in series, and the supply will be from one or more dynamos, the pressure available being from 460 to 480 volts. Each person tendering will be required to submit a drawing of the kind of lamp which he proposes to supply, showing details of construction, and the materials to be used. Specifications, etc., may be obtained at the Engineer's Department, County Hall, Spring-gardens, S.W., upon payment of £1. Tenders by Nov. 13.

RESULTS OF TENDERS.

Bradford.—The Council have confirmed a contract with Messrs. Pollit and Wigzell and the Electric Construction Company, Limited, for the supply of an engine and alternator, at £3,975.

Louth (Lincs.).—The Free Wall Paper Company, Limited, have placed the contract for the electric lighting and power distributing plant in their works with Messrs. Crowther and Co., Manchester.

Birkenhead.—The Corporation have accepted the tender of the Callender's Cable and Construction Company, Limited, 90, Cannon-street, London, E.C., for the supply, delivery, and laying of feeder mains, etc.

Aberdeen.—The Tramways Committee have received a tender for the supply of 25 electric cars, the electric equipment of six of the horse cars, and the supply of spare parts from the British Westinghouse Company, Limited, at £18,439.

Bradford.—The Corporation have accepted the tender of Messrs. Newton, Bean, and Mitchell, Bradford, for engine and dynamo, etc.; and that of Messrs. Collinson Bros., Bradford, for switchboard, arc lamp-posts, etc., for their destructor works Southfield-lane, Bradford.

Hackney.—The Vestry have accepted the following tenders for their electricity works: Dorman, Long, and Co., Victoria-street, constructional ironwork, £3,145; British Insulated Wire Company, mains, including trenching, troughing, cables, boxes, and house service, £46,416. A note referring to these and a number of other tenders will be found in another column.

Eastbourne.—The Corporation have accepted the following tenders for the supply and erection of a water-tube boiler, with fittings, feed pump, etc., a 400-kw. steam alternator, with exciter (vertical enclosed high-speed engine), and main switchboard and connections: Stirling Boiler Company, two boilers, etc., £2,033; Ferranti, Limited, two alternators, etc., £7,850, switchboard, £982.

Longton.—The Gas and Electricity Committee have accepted the following tenders for electric lighting machinery: Electric Construction Company, Wolverhampton, engines, dynamos, boiler, balancer, and switchboard; Chloride Electrical Storage Syndicate, near Manchester, accumulators; E. Green and Son, Limited, Manchester, economiser; Babcock and Wilcox, London, boilers H. J. Coles, Derby, travelling crane.

Brighton.—The Town Council have received the following tenders in connection with rewiring the abattoir premises Hollingdean-road, for electrical installation:

G. Hignett, 5, Clifton-terrace, Brighton	£119 15 0
C. J. Reed and Son, North-street, Brighton	98 10
H. G. Galliers, 21, St. James's-street, Brighton (accepted)	95 0
Page and Miles, Limited, 60, Western-road, Brighton.	54 15

BUSINESS NOTES.

TRACTION.

Paisley.—Mr. Murphy has made yet another offer. A poll of ratepayers is to be taken.

Lowestoft.—The Town Council have agreed to Mr. Walter Beer's terms, and instructions are to be given to him to proceed with his surveys of the proposed tramways.

Darlington.—A motion to rescind a former resolution of the Town Council in support of the Imperial Tramways Company was on the agenda for the last meeting of the Town Council, but was withdrawn.

St. Helens.—The town clerk of St. Helens has been instructed to take all necessary steps with a view to the construction of a loop line along Pecker's-hill-road and Junction-lane, Sutton, in connection with the tramway from Robin's-lane to the borough boundary in Bold-road.

Merthyr.—The arbitration conference upon a variety of important points in which the Merthyr District Council are concerned, on the one side, and the British Electric Traction Company, on the other, in regard to the construction of the new tramlines, etc. commenced in London on Monday last.

Folkestone.—The Corporation have decided to promote a Bill for tramways for the town. As already reported, the scheme will cost £95,000. The Sandgate and military authorities have accepted the scheme. The Chamber of Commerce have passed a resolution expressing their full support of the scheme.

Islington.—At the last meeting of the Vestry a letter was read from the London County Council stating that it proposed to introduce a Bill in the next session of Parliament for powers to construct tramways from the Archway Tavern along the Archway-road to the county boundary, and from the junction in Mildmay-park to Ball's Pond-road.

Darwen.—The Tramways Committee of the Town Council are to confer with Messrs. Leslie and Co. with regard to a proposal to construct a tramway from Bolton to Cadshaw Bridge. The surveyor is preparing a statement showing the cost of street improvements and the purchase of property and fully constructing and equipping the line to Sough.

Bury.—Plans submitted by the borough engineer for a large number of tramway sections have been approved, and will be included in the proposed Bill. The estimated cost of the Bury tramway scheme is about £200,000, and it is thought that in the course of about two years there will be a complete network of electric trams in the borough.

Wigan.—The Town Council's application for consent of the proposed tramway in Standish will be considered at the meeting of the Council on Nov. 5. The Aspull District Council having refused to consent to the construction of the proposed tramway within their district, so much of the proposed tramway as is situate within the township of Aspull will be withdrawn from the Bill.

Digitized by Google

Gosport.—A special meeting of the Gosport and Alverstoke Urban District Council will be held on the 6th for the purpose of considering the following resolution: "That notice be given to the Gosport Tramways Company that it is the intention of the Gosport and Alverstoke Urban District Council to purchase the tramways in accordance with Section 43 of the Tramways Act, 1870."

Newcastle.—The New Tramways Committee have adopted a suggestion of the electrical engineer (Mr. Hopkinson) recommending a larger proportion of double-decked cars in place of long single-decked bogie cars. They have also agreed to let the contract for the new sections of work, including the Stanhope-street and Barrack-road sections, and that the work should be commenced immediately.

Branksome.—The tramway from Poole railway station through the Poole-road to Parkstone, and along the Ashley-road to the County Gates, Westbourne, is making rapid progress. A large proportion of the permanent way is laid, and the iron standards with the long arms for the overhead wires are erected all along the line of route. It is anticipated the lines will be open for traffic soon after Christmas.

Belfast.—A Board of Trade inspector made an official inspection of the tramways laid on the Newtownards-road and the Cliftonville-road on the 31st ult. The tramway company announced that they proposed to commence working on these extensions on Nov. 1, and, doubtless, this intimation will give general satisfaction to citizens, especially those residing in the districts more immediately concerned.

Mr. Yerkes Again.—The *Daily Chronicle* says Mr. C. T. Yerkes announces in the *New York Sun* that, in addition to his Charing Cross-to-Hampstead underground, he will seek to establish surface electric lines, radiating in all directions fan-like from his northern terminus to a common centre. He does not, however, propose doing for South London or the East-end what he is about to undertake for the North.

Halifax.—A letter having been received from the clerks of the Southowram Urban District Council asking for an assurance that the Corporation would take trams into their district, the town clerk has been instructed to reply that the Corporation had obtained powers to construct tramways, with the intention of carrying them into every district named in the Act of Parliament within the period fixed for completion.

British Electric Street Tramways, Limited.—This Company has been registered with a capital of £300,000 in £10 shares, the object being to construct or purchase and equip electric tram and rail roads, etc., to adopt an agreement with the Electric Tram Construction and Maintenance Company, and, further, to carry on in all or any of their respective branches the businesses of mechanical and electrical engineers, electricians, etc.

Lake District Tramways.—The promoters of the proposed electric tramways between Bowness, Windermere, and Ambleside will offer and advertise a scheme, with new plans, for the coming session of Parliament. The company are endeavouring to meet the views of the Ambleside, Bowness, and Windermere Councils as to road widening, and it is expected that much of the recent opposition will not be renewed against the new scheme.

Clerkenwell.—The Vestry have decided to agree with the following resolution of the Paddington Vestry: "That a communication be sent to the Local Government Board embodying a strong expression of opinion in opposition to the suggestion of the President of the Board of Trade to the effect that the London County Council should have further facilities to make proposals for new tramways without the consent of local authorities."

Huyton.—At a special meeting of Huyton-with-Roby Urban District Council, held on the 31st ult., Mr. J. B. Atherton and Mr. F. J. Leslie attended, and on behalf of the South Lancashire Tramway Company explained a scheme for laying a tramline from the city boundary at St. Thomas-road, Broad Green, where the Liverpool city tramways would join it, along Broad Green-road, Roby-road, Archway-road, Huyton, and Huyton-lane to Prescot.

Bolton.—The Tramways Committee have approved of a large number of additional tramways and extensions, and they have requested the Parliamentary Sub-Committee to give directions for the promotion of the Bill authorising the construction of such additional works and for the relaying and doubling of the existing track where necessary. An estimate is to be obtained for the supply and fixing of patent lifeguards to all the cars, and an arrangement will be made for an early interview with the Farnworth District Council as to the electrical equipment of the Farnworth tramways.

Stratford.—At a meeting of the West Ham Town Council on Tuesday a report of the Lighting and Tramways Committee on arrangements to be made for proceeding with the tramway scheme, authorised by the Council's Act of last session, was adopted. The report recommends that Mr. Waller be directed to proceed generally with the plans for the tramway scheme, with the exception of the electrical equipment, in accordance with the terms of his engagement approved by the Council; that the electrical engineer and consulting electrical engineer be directed to proceed with the plans for the electrical part of the undertaking; and that the borough engineer with the plans of the generating station and other buildings required.

Cardiff.—The Tramways Committee on Friday heard the report of a sub-committee on an interview with Mr. Glen, engineer to the Cardiff Tramway Company, stating that Mr. Glen objected to the bonding of the lines at present so as to make them serviceable for electric traction. However, he would recommend his directors to reconstruct the lines in such a way that they would be suitable for electric motive power, and have the system handed over complete to the Corporation at the end of 1901, if a mutual agreement could be arrived at with regard to the valuation of the lines. The sub committee thought that such valuation should be taken. It was decided to obtain the remarks of the town clerk on the report. An offer from the Tredegar estate management was read of a 60 years' lease of the railway siding for the power station on the Newport-road site, and was accepted.

Manchester.—At the meeting of the City Council on Wednesday the Council was asked to approve of a recommendation of the Tramways Committee to the effect that the sub-committee appointed in reference to the Manchester Corporation Tramways Bill of 1900 be authorised to enter into agreements with the Manchester Carriage and Tramways Company and the several local authorities in reference to the reconstruction of the lines, and to the fixing of the dates of accruer of the right of purchase of tramways or otherwise in connection with any arbitration or arbitrations arising under or in consequence of the Manchester Corporation Tramways Acts, 1899 and 1900. Surveys are again being made in the meadows between Eccles and Barton for the line of the Manchester-Liverpool Electric Express Railway prior to the Bill being deposited in the House of Commons.

Gloucester.—The Mayor made a statement at Tuesday's meeting of the City Council with regard to the proposed acquisition of the tramways by the Corporation, and the conversion of the same into an electric tramway (a scheme which has been recommended by the committee). He said that it would be necessary to give a month's notice for any resolution authorising such acquisition, and he, therefore, suggested the postponement of the minutes in regard to the matter. This was agreed to, and it was stated that the meeting to take up the consideration of the matter would be held in the middle of December. We might mention that in consequence of the extension of the city boundaries the whole of the Council was re-elected yesterday, and the number of representatives increased, and considerable local interest is being evinced as to the policy the new Council will adopt on the tramways and other municipal questions.

Rhyl.—At a special meeting of the Rhyl Urban District Council on Tuesday the Council decided to apply for the necessary additional loan required to cover the cost of the installation, £15,000 having already been granted. A lengthy discussion took place regarding the agreement between the Council and the tramway company, by which the former agreed to supply the latter with current. The Council had insisted upon a guarantee that the company would take 150,000 units of electricity per annum, and in turn the company asked that they should be paid a penalty in the event of the Council failing to keep up a regular supply. The Council asked for a car mileage penalty based on the average takings of the company, but the latter suggested that the penalty should be at the rate of £10 per hour. The agreement was referred back to the committee, with a proviso that the penalty should not exceed £2 per hour, and that the Board of Trade be asked to withhold confirmation to the order until the Council had completed the agreement.

Southampton.—At the last meeting of the Town Council the following minutes of the Parliamentary Committee were adopted: "The town clerk submitted the minutes of evidence taken before the Select Committee in the House of Commons, Messrs. R. S. Smith and Co.'s petition thereto, and Chancery writ. Also read the correspondence with Mr. C. Lamport and Messrs. Speechly and Co., in reference to the tramways in Bridge-street and High-street. Mr. Waller submitted and explained his plan showing proposed altered curve in the line in High-street and Bridge-street. It was resolved that unless Mr. Waller's plans be agreed to by the engineers to Messrs. Smith and Co. within 14 days from this date, the town clerk be directed to immediately apply to the Board of Trade to appoint an engineer to arbitrate, pursuant to the terms of the order, as confirmed by Parliament." The Council also approved of a draft agreement with Messrs. Griffiths and Millington, Limited, in substitution for the existing agreement relating to advertising in cars for a period of five years. The old agreement was for £21. 5s. per car, and £13 for the omnibus. The sum mentioned in the proposed new agreement was £18. 10s. per car, £13 for each omnibus, and £10 for the trailers.

Falkirk.—The agreement mentioned in our issue of Oct. 12 has been signed. It is to be a fair and good arrangement. The conditions the company offer to the burgh are the following: For the first five years the company pay to the Commissioners annually at the rate of £100 a mile in name of maintenance and upkeep, after the expiry of five years they were to pay the Commissioners £120 a mile annually for the use of the road. Wherever the line passes through the burgh and for 18in. on either side of the line the road is to be causewayed by the company to the satisfaction of the Commissioners, and in the case of a street already causewayed the Commissioners are to get the causeway setts taken out, the value of these setts being about £2,000. Altogether the burgh will get from the tramway company £300 a year for the first five years, and £400 after that and all these privileges. The use of the streets will be granted to the company for 25 years, when it will be within the option of the Commissioners to acquire the undertaking as a whole on payment to the company in name of goodwill a sum amounting to the profits of the four preceding years. At the end of 30 years the burgh can take it over by arbitration, and the amount they would have to pay in this case would be the profits of the two preceding years. Supposing they did not purchase it even then, they can do so at the end of 37 years under the most favourable method of purchase—under the Tramways Companies Acts—without paying for goodwill, etc.

Central London Railway.—It is impossible to say to day what the effect of Monday's crowd will be on the traffic returns of this favourite London line. The weekly receipts have been growing apace, and they have gone up to £6,102 for the week ending Oct. 27, making a total of £64,498 for the 13 weeks the line has been in operation. This works out at exactly £5,000 per week. Considering that the average of the last 10 weeks is a very much higher one, it might safely be assumed that the annual total will not fall short of £280,000. Assuming that at present the ratio of expense will be 50 per cent.—and we have little doubt that after a short time this figure will be reduced to 40 per cent.—the shareholders will have nothing to grumble at. The total share capital is £2,850,000—all issued—and besides that the Company had power to issue £900,000 of debenture stock, none of which had been issued at June 30 last. Probably £750,000 worth of debentures will have to be issued shortly, £2 000 for expenses already secured on capital account, and £500,000 for the contractor's deferred payment. This, at 4 per cent., means £30,000 a year for interest. That would still leave £150,000 to be kept in reserve for unforeseen needs. Taking the expenses at 50 per cent., this would give a net profit of £140,000, and after payment of £4 on debentures, 3 8 per cent could be divided on the ordinary shares, making £4 for preferred and about £3 12s. 6d. on the deferred stock. At the 40 per cent. ratio this 3 8 would at once jump to 4 8, which would mean over £5. 10s. on deferred stock. Both classes of stock, as well as the debentures, are, therefore, well worth a premium of 20 per cent.

Plymouth.—Mr. J. H. Rider, the borough electrical engineer, has supplied the following reassuring memorandum, to which we are indebted to the *Western Morning News*, at the suggestion of Councillor Page: "As there have been a number of incorrect statements made regarding the accident on the Prince Rock line on Tuesday last, it may be well if I briefly state the facts: (1) The accident was due to a telephone guard wire, and not to a trolley wire; (2) the guard wire did not fall through any defect in itself or in its supports, but because it was knocked down by the trolley of an electric car; (3) the car in question was not one of the regular cars, doing its ordinary rounds, and carrying passengers, but was a new car under test and on a trial run, in the sole charge of the contractors; (4) the trolley left the wire either because the car was being driven too fast round the curve, or because the trolley was improperly set; it broke the guard wire support, which allowed the guard wire to fall upon the trolley wire, where it was burned through, and the ends then fell to the ground. Had the contractor's representative, who was driving the car, remained on the spot until the current had been switched off, and prevented any person from going near the fallen wire, all would have been well. But for some unexplained reason he proceeded into town with his car, leaving the wire unprotected. Telephone guard wires have to be fixed by order of the Board of Trade and the Postmaster General, and they are often the cause of more accidents than they prevent. So long as they are not in contact with the trolley wire they are harmless, but when in contact any person who touches them may receive a shock. As the pressure on the trolley wire is not more than 500 volts, there is practically no danger to human life, a burn, more or less severe, being the usual result. In the event of a similar accident occurring in the future, the best thing is to keep quite clear of any fallen wire, to prevent anybody or anything from touching it, and to send at once to the car-shed or to the electricity works. When it is imperative that a wire should be handled, the hand should be protected with a glove or a cap, or similar article, and no shock will be felt."

Portsmouth.—The scheme of electric tramways for Portsmouth was advanced a stage on Monday, when the Mayor (Councillor H. R. Pink) laid a commemorative tablet in the walls of the electrical tramway power station, which is in course of erection at the rear of Fratton road A large number of persons witnessed the ceremony. The engine-room is, of course, the chief part of the new building; in this instance it is 116ft. long, 49ft. wide, and 23ft. high. The floor, which will be 3ft. higher than the level of the roadway, will be constructed throughout of brick. Three engines, all of the horizontal Corliss type, by Messrs. Yates and Thom, of Blackburn, are destined to do the work of this station. The electric generators will be of the usual engine type, and the dynamos will be by the English Electrical Manufacturing Company, Preston. In the engine-room will also be situated condensers, with independently-driven pumps, and an overhead travelling crane capable of lifting 25 tons. Underneath the engine room will be a basement for pipes, cables, and other accessories required in connection with the engine. A cable subway from this basement will lead under the passage to the roadway at the far end of the engine-room. Space is left for a fourth engine when necessity requires, and provision has been made for fitting and repairing shops. Water-cooling towers are to be used in connection with the surface condensers, by reason of which the cooling water is used over and over again, being pumped up to the top of the towers, whence it descends through a network of small pipes, reaching the bottom quite cold. Electrically-driven fans will be used in connection with the towers to force a current of air through the water as it descends. The whole of the condensing plant in the cooling towers will be made by the Workington Company, London, the pipework being supplied by the Alton Company, London. The roof of these buildings is to be formed by a large cast iron water-tank, in which will be stored about 25,000 gallons, and this immense weight will be carried on trussed steel rafters. The chimney shaft will be 125ft. high, with an inside diameter of 6ft. 6in In the boiler-house will be three Babcock and Wilcox water-tube boilers, each of sufficient capacity to run one of the larger engines. A Green's economiser will be fitted to each boiler, which will also be fed by steam superheaters. Space is provided for a fourth boiler, which would raise the boiler capacity to about 2,500 h.p. The contract price of the building is £10,515, and the machinery £29 656, but it is estimated that the cost of the whole undertaking, including the buying out of the Provincial Tramway Company, who formerly served the town, will be little short of £600,000, or a charge on the town of £30,000 a year for 20 years. The power station is being built by Mr. J. W. Perkins, of Portsmouth, from plans by Mr. E. Porter, electrical engineer.

LIGHTING AND GENERAL.

Aberdeen.—The electrical engineer is about to invite designs and tenders for a single-deck electric car.

Accrington.—The Town Council are making application for power to borrow £1,511 for electric lighting.

Worksop.—The Public Works Loan Commissioners have refused to grant a loan for the electric lighting works.

Dundee.—The extension of electric lighting during the past month is represented by the installation of 697 lamps.

Oban.—The Town Council have decided to apply to the Board of Trade for a provisional order for the electric lighting of the burgh.

Neath.—At a special meeting of the Town Council on Tuesday it was resolved to apply for an electric lighting order for the borough.

Warrington.—It is reported that there is every probability that the electric light will be ready in ample time for the Christmas displays.

Falkirk.—The Town Council intend to apply to the Board of Trade for a provisional order for electric lighting in terms of the Electric Lighting Acts.

Electric and General Investment Co.—Allotment letters in respect of the issue of 19,900 6 per cent. cumulative preference shares have been posted.

Colwyn Bay.—The Urban Council have obtained loans of £5,200 and £364 for electric light, fire brigade, and part of new promenade expenditures.

Shipley.—An order has been received from the Local Government Board authorising the borrowing of £22,000 for the purposes of the supply of electricity.

Cardiff.—Immediate steps are to be taken to institute a canvass of the town to obtain the view of the ratepayers on the advantages of the Post Office telephone.

Beverley.—Application is to be made for a provisional order to enable the Corporation to supply electricity for all public and private purposes within the borough.

South African Lighting Association.—The directors have declared a dividend of 4 per cent. (8 per cent. per annum), free of income tax, being the same as last year.

Stratford-on-Avon.—The following have been elected members of the Electric Lighting Committee: Alderman Hawkes, and Councillors Flower, Holton, North, and Park.

Dover.—The Admiralty Pier is being lighted electrically throughout. The work has been entrusted to Messrs. Donnison, Berlyn, Sillem, and Co., of London and Liverpool.

West Hartlepool.—Messrs. Bennett and Ward-Thomas, consulting engineers, of Manchester, have been instructed to report on a municipal telephone exchange for West Hartlepool.

Todmorden.—The Town Council intend to apply for a provisional order to supply electricity for lighting and motive power, and for all public and private purposes within the borough.

Glasgow.—The number of lamps applied for from Oct. 4 to 18 was 2,337 of 8 c.p. for lighting purposes, and 112 h.p. for motors, equal to 2,928 8 c.p. lamps, making a total of 5,625 8 c.p. lamps.

Poplar.—The District Board have decided to give Mr. Blackman, the electrical engineer, a gratuity of 250 guineas and to strongly recommend the new Council to increase his salary to £500 a year.

Dewsbury.—Colonel J. T. Marsh has held an enquiry into an application of the Town Council for power to borrow £7,500 for the purpose of supplying various districts within the borough with electric light.

Stafford.—An enquiry was held at Stafford on Wednesday before Mr. H. P. Boulnois into the application of the Town Council to borrow £10,000 for the purpose of extension of the electric lighting works.

Wednesbury.—We learn that, whilst as yet nothing definite has been decided upon by the Town Council, it appears certain that no electrical scheme involving any great outlay will be embarked upon at present.

Paisley.—At a special meeting of the Town Council on Tuesday it was agreed to forward a petition to the Secretary for Scotland, asking for additional borrowing powers to the extent of £25,000 for electric lighting purposes.

Bath.—During the quarter ended Sept. 30, 1,652 8 c.p. lamps have been installed by 29 new consumers. When these installations are completed there will be a total of 26,630 8 c.p. lamps connected to the supply mains.

West India and Panama Telegraph Co.—The directors have decided to draw partly upon the reserve fund for the payment of the usual dividends on the cumulative preference shares and 6d. per share on the ordinary shares.

Digitized by Google

Huyton Quarry.—With regard to the recent fire at the Premier Electric Lamp Works, Huyton Quarry, we learn that beyond some damage to the fittings and a quantity of globes ready for exportation destroyed, the loss is inconsiderable.

Hendon.—At Monday's meeting of the Urban District Council the following motion was lost: "That the resolution of the Council passed on Dec. 4, 1899, that the Council themselves carry out a scheme of electric lighting, be rescinded."

Batley.—Mr. Sandford Fawcett held an enquiry on Wednesday into the Corporation's application for sanction to borrow £25,602 to cover the cost of a generating station and the laying of cables for electric lighting in the centre of the town.

Gourock.—The Commissioners are taking steps to ascertain particulars about cost, borrowing powers, etc., with regard to the introduction of electricity into the burgh. The general feeling in the Commission is in favour of a comprehensive scheme.

Leeds.—The Lighting Committee have decided to advertise for tenders for the erection of the extension to the electric lighting works in accordance with the plans of Mr. Charles Brance, of Bradford, who was the architect for the present buildings.

Luton.—The borough engineer and electrical engineer have been asked to confer on the subject of street boxes and standards for arc lamps. The report of the electrical engineer upon tenders for the supply and delivery of meters has been deferred.

Bilston.—The Midland Electric Corporation for Power Distribution have notified the District Council that, in pursuance of orders obtained from it and the Willenhall Council, a number of the main streets in Bilston will shortly be taken up for the purpose of laying mains.

New Edition.—We are informed that Messrs. Whittaker and Co., of Paternoster-square, E.C., have just issued a second edition of "Electric Wiring, Fittings, Switches, and Lamps," by W. Perren Maycock, M.I.E.E. The work made its first appearance just a year ago.

Pacific Cable.—To the present Government of New South Wales belongs the credit of passing through all its stages the often-postponed Bill enabling New South Wales to join the other Colonies and Great Britain in the construction and maintenance of the Pacific cable.

Mansfield.—The Council have passed a resolution affirming that it is desirable to promote a Bill in Parliament for a number of matters, and it is understood that the electric light scheme will be proceeded with even if the part of the Bill relating to the tramway should fall through.

Stratton and Bude.—A Bill to purchase the Bude Harbour and Canal Company's undertaking is to be applied for by the Council during the next session of Parliament, and if obtained it is intended to use the surplus water for the electric light for Stratton and Bude.

London Gazette.—Notices of intention to apply for orders have appeared in the *Gazette* as follows: (1) Electric lighting—Standish-with Langtree Urban District Council, Ripon (City), Atherton Urban District Council; (2) electric lighting and tramways—Atherton Urban District Council.

Pentypridd.—The District Council are consulting Mr. Wilson with a view of selecting a site for electrical works. They have passed a resolution that application be made for a provisional order to authorise the Council to supply electricity for public and private purposes within the urban district.

Wigan.—The Town Council on Wednesday decided to apply for a provisional order of the Board of Trade empowering the Council to supply electricity within the borough. Mr. Miller, C.E., Liverpool, will be retained to advise the Corporation upon all matters relating to the proposed application.

Wandsworth.—The London County Council have consented to the laying of electric light mains by the County of London and Brush Provincial Electric Lighting Company in the following roads: Greyhound-lane, Wimbledon Park-road, Southdean-gardens, Macaulay-road, Beaumont road, Augustus-road.

Southgate.—The Council have sealed an agreement between the Urban District Councils of Enfield, Edmonton, Tottenham, Wood Green, and Southgate, for the promotion of a joint Bill in Parliament to confer powers upon a joint Board of the Councils mentioned to establish electric lighting in the districts.

Price-List.—We have received from Messrs. J. Spencer, Limited, of the Globe Tube and Engineering Works, Wednesbury, a copy of the twentieth edition of their price-list of steel and iron tubes, gauges, screwing machines, trolley poles, etc. The list is very complete, and catalogues tubes for use in all kinds of engineering work.

Rochdale.—At the conclusion of the meeting of the Town Council on the 25th ult. the members walked in procession to their electrical works in Gashouse-lane for the purpose of formally opening them. The Mayor presented Mr. Alderman William James Petrie (the chairman of the Gas Committee) with a golden key with which to perform the ceremony.

Strike.—A further attempt has been made to settle the strike of electrical tramway men at Ashton, Oldham, and Hyde. The men on Saturday withdrew the offer made on the 26th ult. to submit the dispute to arbitration, but it was announced on Wednesday that the Board of Trade have appointed Mr. G. R. Asquith as arbitrator, who at once intimated that all the men should return to work pending his decision.

British Westinghouse Co.—We have received from this firm their circular No. 1,033, which deals with their direct-current engine-type multipolar 125-volt generators for lighting service. The circular contains a full description of the various parts of the machines, these parts also being separately illustrated. Outline drawings are also shown in connection with tables which have been drawn up showing the approximate dimensions of the standard machines. This type of generator is also illustrated when direct-connected both to Westinghouse steam and gas engines.

Hampstead Electric Supply.—A fool and his money are not so soon parted nowadays as formerly. And a good thing, too, it is for the fool. We notice that the shares in the above Company are still being peddled about the country. They don't seem to find too many purchasers, and those who intend to invest in them might, in our opinion, keep their money for better purposes. Although the Company was formed in the summer of 1898 to take over the business of the local Battery Company, no report was available for the compilers of the 1900 "Stock Exchange Year Book." It is significant that there is no market in either preference or ordinary shares on the London Stock Exchange.

Appointments Vacant.—The Ashton-under-Lyne Electric Lighting Committee invite applications for the post of borough electrical engineer to have charge of their electricity supply undertaking.—The Wolverhampton Lighting Committee invite applications for the appointment of chief clerk and canvasser in their electricity department.—The Wrexham Town Council require a borough electrical engineer.—The Farnworth Urban District Council require an engineer for their electrical undertaking.—An engineer competent to supervise staff of assistants and technical workshops, inspect stations, etc., is wanted by Marconi's Wireless Telegraph Company, Limited. Particulars of these vacancies and of others relating to articled pupils, junior station assistants, shift engineers, foreman, etc. mechanical and electrical engineer, will be found in our advertisement columns.

Stock Exchange.—The Stock Exchange Committee have appointed Nov. 14 as a special settling day for Dublin United Tramways Company's (1896) 60 000 ordinary shares of £10 each fully paid, Nos. 1 to 60 000, 59 987 6 per cent. preference shares of £10 each fully paid, within Nos. 1 to 60,000, and £300 000 3½ per cent. mortgage debentures of £100 each, Nos. 1 to 3,000. Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Castner-Kellner Alkali Company's further issue of 150,000 shares of £1 each; and Electrolytic Alkali Company's ordinary shares of £1 each, and 7 per cent. cumulative preference shares of £1 each. The committee have further been asked to allow the following securities to be quoted in the official list: Charing Cross and Strand Electricity Supply Corporation's further issue of 30,000 4½ per cent. cumulative preference shares of £5 each; and Hove Electric Lighting Company's 11,000 shares of £5 each, fully paid, Nos 1 to 11,000. (renewed application).

Wolverhampton.—The Town Council on Wednesday adopted a report of the Lighting Committee, in which it was pointed out that there was a necessity, in order to meet the increasing demand for electricity for lighting and power purposes, to put down extra plant, and recommending that application be made to the Local Government Board for permission to borrow £58 942 on the security of Corporation stock. The amount will include £4,620 for buildings and foundations, £18,140 for boiler-house equipment, £19,580 for engine-house equipment, £15,000 for feeders, etc, and £1,602 to cover the amount overspent on a previous loan. Mr. Gough Allen, in moving the adoption of the report, said it was necessary, owing to the constantly increasing demand for electricity, to have a stand-by plant so as to keep it up to a safe point in case of a breakdown. The committee had never been ahead of the demands which might be made upon them, and it was necessary to be prepared owing to the laying down of the new tramways. The money would not be expended all at once, but as required. If this loan were sanctioned the capital expenditure of the committee would reach £149,000.

W. T. Henley's Telegraph Works.—We have received from the W. T. Henley's Telegraph Works Company, Limited, a handsomely bound and illustrated book, containing an account of some of the work carried on at the North Woolwich works of the Company during the last 50 years. From the book we learn that the business was founded some 50 years ago by the late Mr. W. T. Henley, and up to the time of his death in 1882 the works were almost exclusively devoted to the construction of submarine telegraph cables and underground telegraph lines. After 1882 the business extended in other directions, and electric light and power cables and telephone wires were also made. A list is given of the more important cables manufactured and laid by the firm since 1858, when the Tasmania-to-Australia cable was finished. The Halifax-Bermudas cable is specially mentioned as having been laid in a fortnight and in adverse weather. The length of this cable is 850 knots. The total weight of this cable was over 2,000 tons. A list is also given of the towns, etc., for which cables for electric light and power work have been manufactured. There are at present, we learn, over a thousand hands employed at the works alone, not including those employed outside in the laying of the cables. The new buildings on the river front of the works are described as very large and convenient, and include electrical testing rooms, in which every order executed by the firm is subjected to stringent electrical and mechanical tests. The greater part of the machinery in the works is driven by electricity, and every new workshop opened is run by this means. The illustrations in the book are very well executed, and we must congratulate Messrs. Henley's on having produced such a neat and interesting souvenir of their 50 years' work.

Digitized by Google

Wigan.—The Council have adopted a report from the electrical engineer, stating he had received a much larger number of applications for current than had been anticipated, and it would, therefore, be necessary to put down additional plant. Tenders for the extra plant required will be called for at once.

Partick.—Mr. Maxwell, of Worcester, has been appointed resident electrical engineer for the burgh. Mr. Maxwell will take up his duties immediately. Current will be obtained from the Corporation of Glasgow until the Corporation's own installation is in working order, and it is expected that the light will be turned on in the Dowanhill district before the New Year.

Abercarn.—A conference of representatives from the Nantyglo and Blaina, Abertillery, Abercarn, and Risca District Councils was held on Monday for the purpose of considering the advisability of promoting a joint scheme of public lighting of the Western Valley by means of electricity. It was resolved to recommend the various councils to jointly employ an expert to give a report.

Longton.—At a recent meeting of the General Purposes Committee a communication was read from Messrs. Bennett and Ward-Thomas, consulting telephone engineers, with reference to the subject of municipal telephones. It was decided to defer the further consideration until after the report of the autumn general meeting of the Association of Municipal Corporations had been received.

Ripon.—On Thursday last the Corporation Gas Committee introduced a scheme for spending an extra £7,000 on the gasworks, which several members strongly opposed in view of the introduction of the electric light. Messrs. G. Harrison and Co., electrical engineers, afterwards attended the Council with reference to their report on the electric lighting of the city, which was adjourned for future consideration.

Camborne.—The company which has the undertaking of the Camborne electric lighting supply have made an arrangement with the Urban Electric Supply Company, who are the owners of the Camborne and Redruth tramway order, to furnish them with a supply of electric energy for use in Camborne, and they hope to receive this supply during the course of the next year, when they will be in a position to fully comply with the requirements of the order.

London County Council.—At the weekly meeting of the Council on Tuesday, it was agreed to lend the Bermondsey Vestry £21,000 for dust destructor and electric light installation, and the Poplar District Board £25,000 for electric light installation. Mr. G. L. Gomme, statistical officer to the Council, was appointed clerk in succession to Mr. C. J. Stewart, who recently resigned in order to become chairman and managing director of Samuel Allsopp and Sons, Limited.

Huddersfield.—On Friday evening last the staff and employés met at the electricity works to present Mr. J. R. P. Lunn, the mains superintendent, who is leaving to take the position of borough electrical engineer at Darlington, with a timepiece and ornamental figures, which had been subscribed for by the staff and employés. Alderman Calvert (chairman of the committee) made the presentation, the deputy chairman (Councillor Longbottom) supporting the same.

Bermondsey.—The Vestry are at the present moment carrying out an important combined scheme of electricity generation and dust destruction, as arranged for them by Messrs. Kincaid, Waller, and Manville. The works are now well on the way, and on Monday, the 29th ult., a foundation stone tablet on the chimney shaft was laid by Mr. Thomas Cox, the chairman of the Electric Lighting Committee of the Vestry. A handsome trowel and mallet, with suitable inscriptions, were presented to Mr. Cox by the engineers (Messrs. Kincaid, Waller, and Manville) and the contractors (Messrs. Hughes and Stirling).

Birkenhead.—From and after Dec. 31 next the charge to ordinary customers of electrical energy for lighting purposes within the borough will be reduced to 6d. per unit for the first hour of maximum demand (instead of for the first hour and a half as at present), 3d. per unit for second hour, and 1½d. per unit thereafter; and that the charge for energy for power and heating purposes be reduced from 4d. per unit to 4d. per unit for the first hour, 3d. for the second, and 1½d. afterwards. A new committee is to be appointed to manage the electrical department, which at present is under the Gas, Water, and Electrical Committee.

Cape Electric Tramways Co.—A meeting of this Company will be held at Winchester House on Nov. 14, at 12 o'clock noon, to receive and consider the report of the directors and the statement of accounts to be then presented, to elect directors and auditors, and fix their remuneration, to sanction the declaration of a loan, and to transact the other ordinary general business of the Company. The following resolution will be proposed—namely: "That the capital of the Company be increased by the creation of 100,000 additional ordinary shares of £1 each, ranking for dividend and in all other respects *pari passu* with the existing ordinary shares of the Company, and that the directors be empowered to dispose of such shares to such persons and upon such terms as the Board may think fit." The transfer-books of the Company will be closed from Nov. 12 to 17, 1900, both days inclusive.

Inquest.—At the Greenwich Coroner's Court on Friday last an inquest was held on Arthur Robinson, of 25, Collins-street, Blackheath, who was killed instantaneously at the works of the Blackheath and District Electric Company on the previous Monday. Mark Turner, an apprentice to Mr. E. J. Ford, a builder, of Blackheath, stated that the deceased was employed by Mr. Ford as a carpenter. Whilst fixing fillets round the switchboard on Monday witness heard a groan, saw a flash, and, on looking round, saw the deceased lying on the ground apparently in great agony. He died a few seconds later. They had been warned that it was dangerous, and that they were to be very careful of the switchboard. Another apprentice said he saw the deceased fall back dead whilst apparently in the act of withdrawing the bolt. Witness's opinion was that the deceased's hand slipped in some way on to the switchboard. Dr. Hugh Davies, of East Greenwich, deposed that death was due to an electric shock. Mr. E. Negus Wood, the deputy-coroner, adjourned the inquest for further enquiries to be made. On Wednesday a verdict of "accidental death" was returned.

Criccieth.—A public meeting was held on Saturday to ascertain the views of the ratepayers with regard to the proposal of a Manchester syndicate to introduce the electric light into the town. Mr. Thomas Burnell (chairman of the Urban District Council), who presided, said a gasworks scheme had been dismissed on the grounds that it would be a nuisance, and the price too high. The syndicate would supply the electric light at 6d. per unit, which was equal to 3s. per 1,000 for gas, so that it would be cheaper by 1s. 7d. per 1 000 than at Portmadoc, and cheaper by 2s. 5d. than at Pwllheli. He pointed out that the scheme would be a joint undertaking with the proposed light railway from Portmadoc to Beddgelert, and a scheme to light the town of Portmadoc with electricity. The scheme provides for 12 arc lamps of 1,000 c.p. each. The lamps would have to be provided by the Council, and would cost £10 each, the repayment to extend over a period of 20 years. The annual cost of lighting these lamps would be £109. 10s., or £43 more than the present system of lighting by means of oil lamps cost them. It was finally agreed that the Council should make enquiries as to what it would cost for the Council to go in for a scheme of its own and appoint an expert.

London Docks.—On Tuesday Mr. C. J. C. Scott, the chairman of the London and India Docks Joint Committee, inaugurated the new electric light installation for lighting the London and St. Katharine Docks by switching on the first lamp at the generating station, which is situated at the Hermitage entrance. The electric engineer, Mr. Stanley Bright, was warmly complimented on the admirable manner in which the work has been carried out by his staff, and satisfaction was expressed by the warehouse keepers and the men generally at the brilliancy and uniformity of the light. The illuminating power for lighting the above is equal to 4,000 lamps of 8 c.p. each. The generating plant consists of three Galloway boilers with mechanical stokers, and three sets of Bellis-Crompton engines and dynamos, each set being capable of supplying the current for 2,000 8-c.p. lamps. The wiring is carried out on the three-wire system, with a pressure of 220 volts on either side of the middle wire. The mains are of hard-drawn bare copper mounted on oil insulators, and are run over the warehouses. The seating of plant and running of mains, wiring, etc., has been effected by the Joint Committee's engineering staff. In addition to the warehouses, etc., already mentioned, current is supplied to many of the other warehouses in these docks.

Barnsley.—On Thursday evening, Mr. Councillor Walter Brady, as chairman of the Electric Light Committee, switched the light on to the first 15 arc lamps which have been erected. According to the *Barnsley Independent*, Mr. Brady said the ceremony of that evening might be considered the conclusion of the first part of their electrical works. When they laid the foundation stone of their works a little over 18 months ago, they made an appeal to the inhabitants for loyal support, and he was pleased to say that that appeal had been responded to in an excellent manner. The way in which the light had been taken up was—for a small town like Barnsley—really remarkable. It had been remarked at the time the scheme was suggested that the Council would find out that they had made a great mistake in introducing the light. That remark had been thoroughly falsified. The Corporation had not had to ask the ratepayers for a farthing, and he believed that the undertaking would be entirely self-supporting. He concluded by expressing a hope that the light turned on that night might be typical of the moral and temporal enlightenment which they needed in the town of Barnsley. He then turned on the light amidst cheers. The lamps at present fixed are 15 in number. The pillars are 22ft. high, and have 2,000 c.p. arc lamps. Each pillar is provided with two side arms, having incandescent lamps, which will be used when the current is switched off the arc lamps. After the switching on ceremony, the members of the Corporation adjourned to the King's Head Hotel, where Mr. Councillor Brady entertained them to dinner.

Hackney.—The Electric Lighting Committee of the Vestry having considered a large batch of tenders, with the report of the consulting engineer thereon, recommended the Vestry to accept the following prices from various firms: condensing plant, £1,749; cooling apparatus, £1,960; pipework and valves, £5,065; feed pumps, £733; switchboard and instruments, boosters and motors (part 1), £2,976; ditto (parts 2 to 5), £2,160; public arc lamps and switchboard, £5,248; house meters, £3,632; overhead travelling crane, £638; workshop equipment, £772; arc lamp pillars, 302 at £13. 5s. each. The committee considered 18 tenders for constructional ironwork, the highest being £6,304. They recommended the acceptance of the lowest, that of Messrs. Dorman, Long, and Co., Victoria-street (£3,145), which was in accordance with the specification. The committee further submitted seven tenders for electricity mains, including trenching, troughing, cables, boxes, and house services, and recommended the acceptance of the lowest, that of the British Insulated Wire Company, Limited (£46,416). This firm are now carrying out their first contract in a satisfactory manner, and it was stated that it would be to the advantage of the parish to have all the work carried out by the same firm. The report

Digitized by Google

was adopted after some discussion, during which Mr. Richmond impressed upon the Vestry the fact that since they had received these tenders metal had fallen 10s. per ton, and next week a similar fall was expected. By Christmas iron alone would be down to the tune of 30s. per ton, and copper and other metals were also on the fall. Not a brick of the chimney shaft was yet laid, and until that was completed nothing could be started in the lighting station. After its completion fires would have to be kept under it for a month or six weeks, and it would be 12 months before the chimney could be completed.

City of London.—In his report to the Streets Committee, Mr. A. A. Voysey, electrical engineer and inspector to the Corporation gives a short summary (1) of the events which led up to the granting of the City of London Electric Lighting Order, 1899, to the Charing Cross and Strand Electricity Supply Corporation; (2) of the circumstances under and the conditions on which the City of London Electric Lighting Company obtained permission to alter the standard pressure of supply from 100 to 200 volts; (3) of the circumstances attending the approval by the Board of Trade of the additional system of supply by continuous currents by the City of London Electric Lighting Company. The report also deals with the following subjects: (4) electrical testing; (5) public electric lighting—main streets; (6) public electric lighting—side streets; (7) private electric lighting. We have already dealt fully with the first two items, and we quote the report on the additional system by continuous currents as follows: "On Dec. 20, 1898, the Board of Trade forwarded to the town clerk a description of the additional system proposed to be adopted by the City of London Electric Lighting Company. The Board of Trade were requested by the Corporation, in view of the existing circumstances affecting the question of electricity supply in the City, to delay their approval of the proposed additional system. Their approval was accordingly delayed. In view of the possible introduction of a second electricity supply company into the City, it was obviously undesirable from the point of view of the Corporation that the existing undertakers should establish a second system of mains. The Board of Trade, however, on Aug. 15 gave their consent to the proposed additional system, and should any inconvenience or loss arise from the establishment of such system, the responsibility will not be with the Corporation. I am informed, however, that the use of continuous currents is intended ultimately to supersede the use of alternating currents, a fact full of significance and interest, and it may be hoped that no great inconvenience will arise in connection with the change through the necessity of opening the streets. Only 11 meters were submitted for testing during the year. Nine of them were found to be sufficiently correct, one was found to be 14·4 per cent. fast, and another 3·4 per cent. slow. The Aron meter was approved by the Board of Trade for use on alternating-current circuits, and a number of tests were made with a view to determine the kind of examination that would be necessary before certifying such meters, in accordance with the provisions of the electric lighting orders. Negotiations with the City of London Electric Lighting Company and the Charing Cross and Strand Electricity Supply Corporation are in satisfactory progress for the testing of all meters at Guildhall without any expense to the Corporation. A table is added, giving a comparative statement for the years 1896, 1897, 1898, and 1899 of the interruptions which have taken place in the lighting of the public electric lamps, based on the reports of the police, supplemented by those made by Mr. Voysey. The total number of arc lamps in lighting on Dec. 31, 1896, was 493, and 507 in 1899: the number of lamp failures reported by the police were 609 (1896) and 562 (1899); the number of lamp failures reported by the electrical engineer came to 150 (1896), and to 356 in 1899. The average time per lamp of extinction in minutes was 167 and 180·94 respectively. The total amount of penalties, which was £362. 11s. 3d. in 1896, has fallen to £173 6s. 3d. in 1899, but the proportion of the total time of failure to the time of possible failure—*i.e.*, the total number of lamps multiplied by the total number of minutes during which they should by contract be lighted—rose from 0·1 per cent. to 0·13 per cent. In 1897 it was as high as 0·27 per cent. Dividing the failures into those affecting single lamps and those affecting groups of lamps, we find that the proportion of the time of single lamp failures to the total time of failure rose from 31 per cent. to 35·7 per cent., while the proportion of the time of group failures to the total time of failure fell from 69 per cent. to 64·3 per cent. The number of occasions on which group failures occurred was 12 in 1896, 24 in 1897, 6 in 1898, and 11 in 1899. The arc lamps used for the public lighting are of two types, and the figures given below show approximately the relation between the percentage of failures of each type of lamp for the last four years. Failures of lamps in groups are excluded from the statement, because they have almost always been due to causes outside the lamps. The two types of lamps are respectively designated A and B and the figures showing relation of percentage of failures are (A) 1·35, 1·65, 1·82, 1·99; (B) 1·00, 2·06, 3·20, 2·80 for the four years under review. The Corporation is still without means of testing the value of the supply given to the public lamps. The Board of Trade have not formally approved of any type of instrument for the purpose, but one of the conditions on which the City of London Electric Lighting Company are allowed to change the standard pressure from 100 to 200 volts, is that they establish concurrently with the said change, and under the direction of the Board of Trade, a means of testing the value of the supply to the public lamps." The remarks on the lighting of the side streets are of particular interest. This question has been delayed for several years, in the endeavour to obtain a legal settlement of differences with the City of London Electric Lighting Company as to the meaning of the public lighting agreements. In February the matter came before Mr. Justice Kekewich, whose judgment on the most important point was satisfactory to the Corporation. On another important point—possibly the most important to the company—the judgment was not so satisfactory, and your worshipful committee, acting on the advice of counsel, decided to appeal on that point. Before the appeal was heard, however, the question of the validity of the agreements arose, and it was therefore necessary to postpone the hearing of the appeal. Mr. Voysey says the delay is much to be regretted, because it is undoubtedly possible, by the use of electric lamps, to make a great improvement in the lighting of the side streets without in any way increasing the present cost of lighting by gas. He adds the following upon the electric supply to private consumers: "I was advised during 1899 of two important interruptions in the supply of electricity to private consumers—one affecting the whole of the City, and the second affecting only a portion of the City. Defects in the pressure of the supply occurred on 11 different occasions. At present I have no adequate means of ascertaining how far the City of London Electric Lighting Company comply with their obligations in respect of the maintenance of a proper pressure of supply to private consumers. The company, however, have been put under the obligation to provide such means as the Board of Trade shall direct."

Gloucester.—At a meeting of the City Council held on the 30th ult. the following report by Mr. Robert Hammond, consulting electrical engineer, was presented: "Under Clause 29 of the general conditions attached to the specification issued by me for your electricity works plant, it was stipulated that the tests made at makers' works should be supplemented by 'tests on completion on site,' at your works in Gloucester; and that on these tests being made to the satisfaction of the engineer . . the Corporation 'shall be deemed to have taken over the plant.' In view of the latter stipulation, it was obviously desirable that before the 'tests on completion' were made, the plant should for a month or two prove capable of satisfactorily coping with the work of lighting the city, for which it has been designed. The plant has been so running since July 19, and I have now to report that I have just completed a series of trial runs and tests of every portion of the plant, the work having begun on the evening of Oct. 5, and having extended over the 6th, 7th, 8th, and 9th. In thereby completing the task entrusted to me in connection with your pioneer electricity works, and handing them over to your engineer, I take the opportunity of congratulating the committee upon the gratifying reception given by the citizens to the undertaking, as evidenced by the demand for the light. The works, as you know, after keeping in hand reserve plant sufficient to secure continuity of lighting, have an available capacity of:

Available capacity in kilowatts.	Equivalent in 8-c.p. lamps—All burning at one time.	Equivalent in 8-c.p. lamps—If installed on consumers' premises, say
300	10,000	15,000

and against this capacity your resident engineer advises me that you have actually on the books to-day:

Private consumers—	Equivalent in 8 c.p. lamps—All burning at one time, say	Equivalent in 8 c.p. lamps—If installed on consumers' premises.
Connected and at work	7,206	10,813
Connections ordered	450	675
Signed applications	1,547	2,320
Hitherto reserved for public lighting	2,000	—
If the electricity reserved for public lighting were used for private lighting	—	3,000
	11,205	16,808

It will be seen that these figures exceed the available capacity of the plant, and if all the lights detailed above were actually connected to the circuit there would be grave risk of breakdown. The committee are wisely avoiding this risk by minimising for the present the extent of the public lighting, which on its present basis is only equivalent to 730 8 c.p. lamps all burning at one time. In this connection I beg to remind you that out of the sum sanctioned by the Local Government Board for public lighting there still remains unexpended a balance of £2,300. By dint of delaying any extension of the public lighting until the new plant is at work, you will be able to continue to cope comfortably with the present load by means of the present plant. It is, however, extremely fortunate that the Council had the foresight to put the new set of plant on order, as otherwise no extension of the public lighting could be carried out, and it would be necessary at an early date to refuse new business from private consumers. The additional plant, however, will double the available capacity of the works, bringing it up to 20,000 8 c.p. lamps all burning at one time, or 30,000 8 c.p. lamps if installed on consumers' premises. Even with this capacity it will be incumbent on the committee to carefully watch the progress of the connections, bearing in mind that usually nine months elapse between the date of specification and the setting of new plant into operation. I beg to point out that if an arrangement be come to with the tramway company to supply them with current, additional plant will at once be needed. With regard to the total commitments on capital account to date, I beg to submit the following statement: amounts sanctioned by the Local Government Board—(*a*) original works, £43,450; (*b*) extensions, £9,425; additions to buildings, furniture, etc., £250; cost of preliminary running expenses, stands, stores, coal, etc., prior to July 19, £200—£53,325 (less balance in hand unexpended on public lighting, £2,300); commitments to date of public light

Digitized by Google

undertaking, £51,025. With regard to the buildings, I beg to acknowledge my indebtedness to my colleague, Mr. Harry Dancey, who has been most painstaking in carrying out his portion of the work. The additions and improvements to the buildings which suggested themselves during the progress of the work have, it will be noted, only involved an excess expenditure of £250, and in the case of the engineering work the total of £36 074 has only been exceeded by £200, for both of which items you have good value to show. I trust that the undertaking will prove as successful to the citizens as the prospects appear to promise at the present time." The Electricity Supply Committee unanimously resolved: "That as the prescribed tests have been carried out, and the electricity works have now been handed over to the Corporation, the Council be recommended to appoint Mr. W. J. Bache as resident engineer, at a salary of £250 a year, the appointment to be terminable by a month's notice on either side." A memorial was received, signed by upwards of 200 ratepayers residing near and frequenting Lower Barton street, requesting the Corporation to provide arc lighting for that portion of the city as early as possible. The Council were recommended to erect additional arc lamps (on two circuits) in Lower Barton-street, and to give the necessary orders forthwith if arrangements can be made for the work to be completed within a reasonable time. The city surveyor and Mr. Bache were instructed to further consider the general question of extending the arc lighting, and to report upon the matter in time to allow of any further extension that may be agreed upon being completed by the autumn of next year. Mr. Bache reported that he had carefully considered the question of the charges that should be made in respect of the arc lighting, and recommended that for the present limited number of arc lamps the charges should be as follows: for lamps burning all night, £24 per lamp per annum; for lamps burning till midnight, only £20 per lamp per annum. The Council were recommended to adopt these charges for the present. The committee decided in lieu of the present meter rents, the Council be recommended to adopt the following charges for the hire of meters: up to the equivalent of 20 meters of 8 c.p., 1s. 6d.; 50, 2s.; 100, 3s.; above 100, 4s. per quarter. In cases in which Section 1 of the fourth schedule of the Gloucester Corporation Electric Supply Order, 1896, would authorise a minimum charge of 13s. 4d. per quarter, a charge of only 10s. is to be made until further order, and the accountant was authorised to settle any accounts already sent out for the minimum charge of 13s. 4d. on payment of 10s. The appointment of Mr. Bache was confirmed by the Council and the minutes adopted. Shortly after nine o'clock on Monday night the electric light in the streets of the city and on the premises of a few private consumers suddenly went out. The throwing of the principal thoroughfares into darkness caused some little excitement on the part of the passers by, but the inconvenience proved to be but temporary, for in about 10 minutes the light was once more shining brilliantly. At the meeting of the Council the Town Clerk, at the request of the Mayor, explained that he was at work at the time of the mishap overnight, and he went at once to the electricity works. He found Mr. Bache at the switchboard, and discovered that the occurrence was not of a serious nature. Mr. Bache wrote that morning that an accident occurred to the brush-holders, but this was remedied, and the plant was running again at half-past one. In reply to a question, it was stated that steps were being taken to obviate the possibility of a recurrence.

PROVISIONAL PATENTS, 1900.

OCTOBER 22.

18806. Improvements in trolleys and junction frogs for use on electric railways and tramways. David Blythe Foster, George Percival Gibson, and Herbert Foster, 6, Victoria-road, Leeds.

18813. Improvements in electric locomotives. Bertram Hopkinson, 26, Victoria-street, Westminster, London.

18816 Improved electrical indicator for use with alternating-current apparatus. Charles Lorenzo Clarke, 321, High Holborn, London. (Complete specification.)

18826. Improvements in electric arc lamps. Hugo Bremer, 42, Neuenweg, Barmen, Germany.

18834. Improvements in voltmeters. Nicolas Vasilesco-Karpen, 72, Cannon-street, London.

18855. Improvements in connection with electrically driving machine tools or other mechanism. Thomas Humpage and Epicyclic Manufacturing Company, Limited, 55, Chancery-lane, London.

18865. Improvements in apparatus for the production of electrical oscillations. John Ambrose Fleming and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery-lane, London.

OCTOBER 23.

18874. A revolving centre-piece for two-storey electric cars. Wm. Henry Dunn and Edward Scott, 112, Park-lane, Little Horton, Bradford.

18880. An electrical indicating or recording apparatus for restaurants or other places. James Ferris McLaren, 115, St. Vincent-street, Glasgow.

18889. A new or improved electrically-operated billiard marker. Vernon Hope, 55, Market-street, Manchester.

18898. Improvements in electric recording instruments for motorcars. Paris Singer, Oldway, Paignton, S. Devon.

18904. Improvements in or relating to thermo-electric batteries. West James Crawford and Thomas Battle Turley, 111, Hatton-garden, London. (Complete specification.)

18914. Electric meters. Thomas Alva Edison, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18921. Improvements relating to electric furnaces. Gustaf Benedicks, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18924. Improvements in electric switches. William Howard Chipperfield and Edward Samuel Cook, 4, Dane's-inn, Strand, London.

18925. Improvements in electric switches. William Howard Chipperfield and Edward Samuel Cook, 4, Dane's-inn, Strand, London.

18934 Improvements relating to electric incandescent lamps. Robert Trimmel, 45, Southampton-buildings, Chancery-lane, London.

18940. Improved means for the electrical illumination of the dials of ships' telegraphs and for similar purposes. Eversheds and Vignoles, Limited, and Sydney Eversheds, 1, Queen Victoria-street, London.

18967. Improvements in electric incandescent lamps. Robert Bolton Ransford, 24, Southampton-buildings, Chancery-lane, London. (Albert William Wallace Miller, United States.) (Complete specification.)

18975. Thermo-electric generator. William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Merle J. Wightman, United States.)

OCTOBER 24.

19039. Improved process for the electrolytic oxidation of solutions of chromium oxide salts. Conrad Schneider, 39, Middleton-buildings, High-street, Islington, London.

19050 An improved electric circuit closing thermometer. Frank Cossor, 53, Chancery-lane, London.

19058. Improvements in electrical brakes for railway cars. Frank Clarence Newell, 322, High Holborn, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, March 28, 1900, being date of application in United States.)

OCTOBER 25.

19071. Improvements in and relating to a magneto-electric generator with governing arrangements for ignition purposes on motorcars, stationary gas and oil engines, and other purposes. Frederick Truby Reid and William Shepherd, 117, Sidwell-street, Exeter.

19072. Improvements in electric accumulators. George James Gibbs, 76, Heslington-road, York.

19076. Improvements in or in connection with means for electrically lighting miners' safety and similar lamps. John Charles Best, 30, Park-row, Leeds.

19095. Improvements in or applicable to electric ceiling roses, electroliers, and the like. Charles William Watling, jun., 4, St. Ann's-square, Manchester.

19099. An improved electrode for accumulators of electricity. Jacob Myers, 11, Ramen Hoorn, Holland. (Complete specification.)

19114. Improvements in or applicable to searchlight and signalling apparatus. Mervyn Hanbury Lowther Clark, 321, High Holborn, London. (Complete specification.)

19118. Improvements in secondary electrical batteries or accumulators. Peter Stiens, 65, Chancery-lane, London.

19119. Improvements in or connected with the electro-deposition of metals or metallic alloys. George Edward Vaughan, 57, Chancery-lane, London. (Helmuth Koegel, Germany.)

OCTOBER 26.

19151. Improvements in trolley heads for overhead conductors of electric railways. Ridley James Urquhart and Henry Goodwin, 5, Clayton-square, Liverpool.

19163. A frictionless balance for weighing gravitational, electric, or other forces. William Thomson, Baron Kelvin of Largs, 154, St. Vincent-street, Glasgow.

19167. Improvements in and relating to electrical resistances variable by light and certain other rays or waves, and in the manufacture of the same. James Tarbotton Armstrong and Edgar Alfred Goddin, 40, Vartry-road, South Tottenham, London.

19183. Improvements in and connected with electrical pushes and switches. Edgar Godwin Harcourt, 5, Corporation-street, Birmingham.

19208. Improvements in the production of chlorine and pure solution of alkaline hydrates by the electrolysis of dissolved alkaline chlorides. Paul la Cour, 4, South-street, Finsbury, London. (Complete specification.)

19218. Improvements in dynamo-electric machines and motors and in means for regulating the same. Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

19220. Improvements in unions or connections for electric light pendants and other fittings. Hugo Hirst and John Hillery Collings, 165, Queen Victoria-street, London.

19223. Improvements in or relating to electrical ignition devices for explosion engines. Zebulon Wirt, 111, Hatton-garden, London.

NOTES.

Motor Fire-Engines.—With respect to another note appearing in this issue, it is interesting to note that the London County Council at their meeting on Tuesday last resolved to try some experimental motor fire-engines. It was stated that if these turned out to be successful, the whole of the engines would be similarly equipped.

Institution of Junior Engineers.—On Saturday last a large party of the members of this institution visited the Millbank-street station of the London Hydraulic Power Company. The company have four pumping stations in operation, and a fifth in course of erection, over all of which the party were conducted. At the conclusion of the visit Mr. Percival Marshall, chairman of the institution, expressed the thanks of the members for the attention shown to them.

The Electrical Men on Parade.—In the sound money parade which took place on a recent Saturday in New York, the Electrical Industries Association was largely represented. It is difficult in this country, where we do not have to elect the supreme head of the State every four years, to understand the excitement which such an election causes. Thus, while we can quite see that large interests are at stake, it is not clear how these interests are served by some 100,000 men marching in procession through the heavy rain in order to show on which side their sympathies are. We gather from a short notice of this parade in one of our electrical contemporaries that from 3,000 to 5,000 electrical marchers were expected to be present.

Wireless Telegraphy.—Further experiments have, we learn, been conducted at Dovercourt with the Marconi system of wireless telegraphy. For a considerable time past the Marconi Wireless Telegraph Company have had a station at Dovercourt, and on Monday last it was decided to have a trial of the apparatus at that place. The messages were passed between the land and the Belgian mail steamer "Princess Clementine," which had on board as operators Messrs. F. Stacy and C. Ricard. The signals were commenced when about half-way on the journey, and the messages were quite successful. The working of the apparatus was explained to the Japanese Ambassador at Paris (Mr. M. S. Kurino), who happened to be crossing.

Royal Institution.—The annual course of Christmas lectures for young people at the Royal Institution is, we are informed, to be delivered by Sir Robert S. Ball, F.R.S., Lowndean Professor of Astronomy in Cambridge University, the subject being "Great Chapters in the Book of Nature." The first lecture will take place on Thursday, Dec. 27, at three o'clock, the remaining lectures being delivered on Dec. 29, and Jan. 1, 3, 5, and 8. At a general monthly meeting of the institution on Monday last the special thanks of the members were returned to Dr. Frank McClean, F.R.S., for his donation of £50 to the fund for the promotion of experimental research at low temperatures, and to Dr. Rudolph Messel for his present of a bronze bust of Sir Humphry Davy.

A Novel Escape.—An interesting piece of information comes from Tennessee, U.S.A., which states that two convicts made a good bid for escape from the penitentiary at that town by using pulleys on the telephone wires. The story of the escape, which is truly American, is related by a contemporary as follows: "Two desperate convicts recently made their escape by sliding down two telephone wires from the top of a three-storey building to a point outside of the high stone walls. Both worked in the harness department, and after roll-call managed to return to the building and gain the roof. They had provided themselves with two big pulleys and a wadding used in the manufacture of bridles. The convicts mounted two slender telephone wires, bicycle fashion, and on this took their coast to freedom, the men passing 15ft. over the wall." It was some time before the escape was discovered, but the men were eventually caught.

Car Fenders.—It has been often said that the guard attached to an electric car is of no value as a preventive of serious accidents. This, however, does not appear to be quite correct, as two accidents which occurred recently in Liverpool would tend to show. During the afternoon an Irish pig, which was in Gill-street market stalls, managed to escape into the street and ran down into London-road, where it rushed full tilt against an electric car. The animal was knocked down, picked up by, and landed on the guard, where it sat squealing until taken off. The other accident was a more serious case. It appears that a girl, aged eight, was crossing West Derby-street, when she was accidentally knocked down by an electric car. She was picked up and carried about 20 yards on the guard, and was ultimately rescued from what might have been a shocking death, having only received a few bruises on the forehead.

Rontgen Society.—Dr. J. B. MacIntyre, in the course of his presidential address to the Röntgen Society recently, said that the use of X-rays in war had everywhere created a great amount of interest. The first definite work in this direction had been done in the Soudan Expedition, where some good results were obtained. They were eagerly awaiting a paper from one who had had experience with the X-rays in the South African War, but it was too recent then to say anything as to their use. He was, however, able to report through the courtesy of Surgeon-General Jamieson, the Director-General of the Army Medical Department, that the X-rays were found most useful in the hospitals at the base and on the lines of communication although not actually on the field. There was now a regulation list of apparatus for army work; 17 sets were sent to South Africa, and they were being adopted in all the larger military hospitals.

Calcutta Telegraph Office.—In marked contrast with the good work done by the Telegraph Department of India in laying telegraph lines across difficult country, etc., is the way in which the local telegraph service appears to be carried on in Calcutta. Thus messages which may or may not be important are constantly being wrongly delivered, and any scrawl is taken as a receipt by the man who delivers the telegrams. Complaints have, we learn, been frequently made by leading persons in Calcutta, but instead of the charges being investigated, they are treated with indifference by the officials at the chief office. It is a great pity, therefore, that the Indian Government does not take notice of these complaints which often appear in the Calcutta local Press, and ensure, by strict measures if necessary, that the business of such an important town as the capital of India shall not be interfered with by the indifference of a few telegraph officials.

Power Scheme.—There is, we learn, now being arranged an important scheme for the electrical distribution of power for manufacturing and other purposes throughout the Middlesbrough, Stockton, Hartlepool, and Cleveland district, and a Bill applying for the necessary parliamentary sanction is to be introduced next session. The scheme, which is supported by many of the most influential manufacturers in the district, is to be drawn up on similar lines to the Lancashire, South Wales, and Durham District Power Bills, which were passed last session. The engineer in connection with the scheme is

Digitized by Google

Mr. A. A. Campbell Swinton, M.I.C.E, of Victoria-street, Westminster, Messrs. Jackson and Jackson, of Middlesbrough, being the solicitors. We must congratulate the promoters of the scheme on securing the services of so eminent an engineer as Mr. Campbell Swinton, under whose direction the scheme, if passed in Parliament, cannot fail to be successful.

Power Factor Indicator.—In the *Electrical World* for Oct. 27 Mr. A. J. Bowie, jun., describes the theory of an instrument by which the power factor of a given supply may be practically measured. The principle of the instrument is the use of two dynamometers on the same suspension. The instrument would, we understand, consist of a single controlling field, which would be fixed, and through which the current supplied would pass, and two moving coils. These moving coils would receive respectively the voltages of a non-inductive supply, and cross the supply terminals of which the power factor is required to be known. The angle of these two moving coils would not be the same with respect to the fixed field. The author then develops the formula by means of a calibration instrument made to work out mathematically, but he advocates that, besides this, independent readings should be made to prove the accuracy of the scale. Such an instrument would be extremely useful in practice.

The Smoke Problem.—It is pleasant to hear, on the authority of Mr. Stevens, of Brighton, that the terrible question of smoke prevention has been solved at last. To this end Mr. Stevens has invented a machine, and now only requires the necessary money to work the invention. This he hopes to get by the sale of a patent washerless tap. The machine which is to prevent the smoke nuisance is apparently an electrical machine, which, if given a first help off, will go on working, and when working produces more electricity to work itself. This machine would, therefore, in addition to solving the smoke problem, appear to solve the problem of dear coal. The electricity, which will always be on hand when wanted, is to be used for everything for which coal is now used, and also many things for which it is not. We are afraid, however, that until the sale of the tap has reached much greater dimensions than is usually the case with such things, London and other places will still have to patiently endure their fogs.

Electrical Works Extensions.—Our recent note on the large number of new works which are now being erected throughout the country, has resulted in us receiving a letter from the Luton Chamber of Commerce calling attention to the advantages of Luton as an industrial centre. A joint committee of the Town Council and Chamber of Commerce will be pleased to supply all information to firms requiring sites. The letter we have received is signed both by the town clerk and the secretary of the Chamber of Commerce, which shows that the two bodies are working together in perfect harmony. In the selection of such sites it is not only the local advantages which have to be considered, but also the treatment which the new firm will receive at the hands of the local authority. In too many instances this treatment as far as rating is concerned is not just, and hence the desire of firms to get into districts where they will be free from municipal responsibilities. We should say, however, that in the present case the above remarks would not apply.

Electro-Harmonic Society.—A ladies' night evening concert in connection with the Electro-Harmonic Society is to be held on Friday, 16th inst., at the St. James's Hall Restaurant. Special interest will attach to this concert from the fact that Major Crompton, who recently returned from South Africa, is to preside. There has been prepared a very full and select programme, which should provide the audience with quite a feast of music. There are to be several part songs by the Westminster Glee Singers, and each of the gentlemen composing this quartette is down to sing a separate song. Miss Elsie Mackenzie is to give two songs, and piano solos are to be provided by Mr. A. E. Izard. The glassophone solos by Mr. G. Nelson should be very pretty, and one may expect to have a good hearty laugh when Mr. R. A. Roberts gives his humorous selections entitled "Shrimpot Sands," and "A Travesty in Rhyme." The musical directors of the concert will be Mr. A. E. Izard, R.A.M, and Mr. T. E. Gatehouse. The concert will commence at eight o'clock precisely.

The Dangers of Electrical Safe-Breaking.—Much has been said as to the ease with which a safe or strong-room can be broken into by the use of the electric arc. That this is not so simple as it would appear at first sight is shown by the experience of two gentlemen in Ohio. Thus, the big iron safe in the Middleport shoe factory refused to open, and the book-keeper, Mr. Louis Jaquith, and engineer, Mr. Walter H. Rice, conceived the idea of burning out the combination by use of the electric arc. It took several hours to accomplish their purpose, but they finally succeeded, but not until they had stood for several hours in the glare of the electric light, taking turns at holding the wire and carbon. When the work was over both complained of a dizziness and pain in the head which increased as the hours passed, and in a short time both went suddenly blind at about the same time. All efforts to restore their sight have been unavailing, for while the eyeballs appear all right, the sight is destroyed. The unfortunate conclusion to this experiment should, we think, warn any professional safe-breaker against the use of this improved means of accomplishing his ends.

Evening Technical Schools.—The issue of the *London Technical Education Gazette* for September and October is a double number, and contains a list of all technical evening classes in London, with the exception of those in connection with the London School Board. The Technical Education Board is, we learn, preparing a complete list of evening Board school classes in London, and this list will contain particulars as to the subjects, etc., which are taken in the evening schools. The subjects taken in the various schools are classified into seven sections—viz., science, engineering, trade and technical classes, domestic economy, art, economic and commercial subjects, and music. In Section 2 one finds the engineering subjects, there being listed 19 schools and institutes which take mechanical engineering, nine which take electrical engineering, and eight which take civil engineering. In Section 3 the subjects taught are classified under the headings of the various trades, there being taught in the electrical classes instrument making, electrical wiring and fitting and electro-plating. Altogether, the list should be very useful to those wishing to gather information as to the subjects taught in the various London technical institutes, and as to the cost per course or term for the teaching of these subjects.

A Danger to Ships.—In its issue for Oct. 6 the *Scientific American* had an article dealing with the electrolytic action caused on ships' bottoms by the combination of copper and iron and sea-water. The electrolytic action of these three substances was commented on as being very dangerous to ships. Mr. E. A. Suverkrop now writes to our contemporary to the effect that it was common practice some years ago to put copper strainers or bilge "strums" at the ends of the suction pipes of bilge pumps in wooden steamships. In course of time, when iron replaced wood in shipbuilding, the copper strainers were retained; several

Digitized by Google

mysterious losses of ships at sea during fair weather occurred. One steamer went down at her moorings in the Mersey. When she was raised, it was found that there was a round hole in her bottom where the copper strainer had been. This led to investigation, and it was discovered that in many iron boats, where the inner coating of Portland cement which is usually put in the bilges of iron and steel vessels had been removed by any means, so that the copper strainer could rest directly upon the iron shell, the galvanic action had eaten the iron almost entirely through. It is evident, therefore, that considerable attention should be given to this subject, and a means found for preventing this eating away of the iron from such a cause.

Horse v. Automobile.—A decision which should have the effect of encouraging the use of the automobile in the United States was recently given by Justice Sutherland at Rochester, U.S.A. The claim was one for damages caused by a runaway horse after having been frightened by an automobile. A decision had previously given in favour of the owner of the horse on the ground that the owner of the automobile was liable because his machine had frightened the animal. An appeal was brought, however, and Justice Sutherland reversed this decision, and declared that the law on the subject would be as follows: "The horse has no paramount or exclusive right to the road, and the mere fact that a horse takes fright at some vehicle run by new and improved methods, and smashes things, does not give the injured party a cause of action. If the defendant's motor carriage is practicable for the purpose of travel, and the noise and vapour caused by its use are kept within reasonable limitations, and are no greater than are fairly incident to the use of motor carriages which are found adapted to the needs of the general public, then I cannot see how the defendant can be held liable in the absence of evidence that at the particular time complained of the carriage was operated carelessly. The temporary inconvenience and dangers incident to the introduction of these modern and practical modes of travel upon the highway must be subordinate to the larger and permanent benefits to the general public resulting from the adoption of the improvements which science and inventive skill have perfected."

King's College Science Laboratories—The new scientific laboratories at King's College were opened on Tuesday, Oct. 30, by Lord Lister. Amongst those present were Dr. Robertson (the principal of the college) and others connected with the staff, the Lord Mayor, the Lord Chief Justice, etc. The Principal, in introducing Lord Lister, said that the work which had made that gentleman famous was connected with King's College. Lord Lister then said it might seem strange that so large a gathering of distinguished men should come to witness the opening of certain laboratories. Yet the occasion was not unworthy of celebration, it being an event of significance in regard to the provisions for higher education in the Metropolis. It was recognised that mere lectures were not sufficient, that practical instruction was imperatively necessary. Some branches of King's College were long ago well equipped to this end, but not all. The dissecting-room was by no means adequate, and the accommodation for the practical teaching of physiology was miserable, while there were smaller defects in other departments. Of these the council had long been conscious, and to remedy them had provided the new laboratories, which were highly satisfactory. It was a happy coincidence that this great addition to the resources of the college had been made at the time when it was entering on a new career as one of the colleges of the new University of London. He himself would have liked to see the old examining university retained and a separate teaching university established, but other views prevailed, and a compromise had been effected under which examining and teaching existed side by side in the same institution. He wished the compromise all success, and hoped that now the matter was decided all would work together for the common good. The Lord Mayor moved a vote of thanks to Lord Lister, which was seconded by the Hon. W. F. D. Smith, M.P., and adopted. Lord Lister then formally declared the laboratories open. In all the new rooms electric light has been fitted, and great care has been taken with the natural lighting. The fittings in all cases are of the latest design.

Municipal Electrical Association.—We have received from Mr. A. B. Mountain a copy of the *Proceedings* of the Municipal Electrical Association for the years 1899 and 1900. The copy for the year 1899 contains the presidential address delivered by Mr. H. Faraday Proctor on June 14, 1899. After this come papers read by Councillor G. Pearson on "Municipal Trading"; "Appropriation of Profits, etc.," by Bailie Mackay; "Combined Traction and Lighting Works," by Mr. J. H. Rider; "The Municipalisation of the Telephone," by Mr. A. B. Mountain; "Notes on Distribution of Electricity," by Mr. C. D. Taite; "Condensers for Electric Light and Power Stations," by Mr. J. F. C. Snell; "The Arrangement of Steam-Pipes," by Mr. J. E. Edgcome; "Notes on the Performances of Single-Phase Motors," by Messrs. J. R. P. Lunn and P. S. Thompson (associates' prize); "The Choice of Meters," by Mr. C. A. L. Prussman; "Electric Light Mains," by Mr. D. Clothier. Reports of the visits of the association, annual dinner, business meeting, hon. secretary's report, and the report of the committee on dangerous trades are also given. The *Proceedings* for 1900 contain the presidential address by Mr. A. B. Mountain. The papers published are those read by Alderman Potter and Mr. H. C. Bishop on "Means for Stimulating the Demand for Electrical Energy," and on "Electricity Works for Small Towns," by Messrs. C. S. Vesey-Brown and G. M. Harriss; "Electric Motors," by Messrs. T. P. Wilmshurst and C. A. L. Prussman; "The Combined Management of Tramways and Lighting Departments," by Mr. R. C. Quin; and "Methods of Reducing Light-Load Losses," by Mr. H. L. P. Boot; "The Distribution of Electricity in Scattered Areas," by Messrs. L. Andrews and G. Wilkinson; "Maintaining Certain Portions of Electrical Distribution Systems at Earth Potential," by Mr. C. H. Wordingham; "Impressions of Present American Tramway Practice," by Mr. A. E. Le Rossignol; and "Protection of Telegraph and Telephone Wires," by Mr. R. C. Quin. The *Proceedings* conclude with the usual reports, etc. These volumes, which contain a large amount of very useful information, can be had from Mr. A. B. Mountain, Corporation Electricity Works, Huddersfield, at the price of 3s. 6d. per copy.

Automobile Trials.—The first of the electric automobile trials under the auspices of the Automobile Club, and of which we gave details in a recent issue, took place on Tuesday last. The run was to be over a given course for an unlimited distance on one charge, the driver to declare to the official observer when the run was finished. The course on Tuesday was a circular route from Chislehurst, the total distance being 34¾ miles. If, however, it was wished to make a continuation of the run, a small circular route from Chislehurst of about 8¾ miles could be gone over as many times as wished. In connection with the trials on Tuesday, the route was severe and the roads in a very heavy state, owing to the large amount of rain which had fallen for the few days beforehand. The vehicle which covered the greatest distance was the

Digitized by Google

"Powerful," which was entered by the British and Foreign Electrical Vehicles Company. This vehicle, which covered 59 miles, carried two passengers. The same company's "Columbia Stanhope" traversed 7½ miles, and their delivery van chose an easier route, going seven miles, but failed to carry her three passengers all the way. Mr. Hart's "Toujours Contente" travelled 34 miles with two passengers, and the National Motor Carriage Syndicate's "Joel" car carried two passengers 37 miles. Two cars entered by the Electric Motor Power Company ran 17¼ and 35 miles respectively, each carrying two passengers. The Canadian Electric Motor Company's "Still" carriage carried four passengers 18 miles, and the Electrical Undertakings car conveyed two passengers 35 miles. On Wednesday there was a hill-climbing trial on a route between Chislehurst and Knockholt, the distance being some 30 miles. On this route the road between Green Street Green and Cudham rises from 300ft. to 680ft. above the sea, and at Knockholt it rises to some 735 above sea-level. The results of this trial have not yet come to hand. On Thursday was to be a trial over 30 miles of average road, and on Friday an optional trial over an unlimited distance on one charge. A note at the end of the official programme bestows praise on Prof. Boys, Mr. Holden, Mr. H. Edmunds, Mr. Harmsworth, Mr. Llewellyn Preece, and Mr. Hanning for the assistance they have rendered in various ways in helping towards the success of the trials.

Nickel Extraction.—The Nickel Copper Company, of Ontario, have recently been experimenting with a new process of nickel and copper extraction. The process is the invention of Mr. H. A Frasch, and it is said to be very successful. As applied to the Sudbury copper-nickel matte, the process consists, says the New York *Engineering and Mining Journal*, in the electrolysis of a brine solution in such a manner that, while the sodium ions are set free at the cathodes with the formation there of caustic soda, the chlorine ions are liberated in the anode section containing the matte and immediately form a chloride solution of the metals present. In this way brine is electrolysed to form caustic soda, at less expense, it is claimed, than with the insoluble anodes in the Castner-Kellner or Rhodin processes, and at the same time the chlorine, instead of being made into bleach, is utilised for the formation of the chlorides of copper, nickel, iron, and other metals that are in combination in the matte at the anode poles. The metallic chlorides can be directly treated for the contained metals by electrolysis or chemical methods, or after being electrolysed of half the content of copper they may be used for lixiviating the metals in the raw matte, the copper chloride acting chemically as a solvent for the metals in the matte, and making the electrolyte solution suitable for further electrolysis. Eventually the metals in the solution are recovered by electrolytic deposition, or in the case of nickel and cobalt the nickel is separated from the cobalt as a chemical salt by a method which is not as yet made public. The matte is crushed and conveyed to the vats, where it is charged directly on a layer of carbonaceous material forming the anode section at the bottom. On this layer of matte is placed a thin layer of sand, which gives a good diaphragm for the separation of the resultant solutions of caustic soda and the metal chlorides. The anode section of the vat is then filled to the sand layer with a saline or weak chloride solution, and the balance of the vat is filled with water or a weak caustic solution. After the passing of the solutions through the vats, the subsequent handling of the solid material, which remains in the anode section after treatment, consists of the removal of the upper layer of sand, which can be washed and used again, followed by the removal of the leached material, from which, perhaps, it might be well to extract the sulphur. Tests carried out by the Nickel Copper Company are said to have given excellent results, and it is claimed that the entire cost of the process will be fully met by the value of the caustic soda and other by-products.

Electrical Fire-Engines.—As may be remembered, some few weeks ago the firemen of Paris gave an exhibition of fire drill before their provincial and foreign colleagues, the apparatus used on this occasion being of an improved character. Three new types of automobiles in connection with the fire service have, we gather, been introduced, each type being used in the drill at Vincennes. The electrical hose wagon has been in use for some months past, and consists simply of an automobile capable of seating six men, and is provided with lengths of hose, life-saving tackle, and ladders. Another vehicle is the electric fire pump, which is of an entirely new type. It consists of a metallic tank capable of holding 100 gallons. This is mounted on an automobile carriage, together with a pump, hose, and nozzle. The motor which drives the automobile is switched off on arrival at the fire, and is switched on to work the pump. This is effected by an ingenious system of gearing, which is applied to work the pump or otherwise. The hose is wound on a cylindrical piece of metal, and is so fixed that on arriving at a fire a stream of water is at once available, and the 100 gallons of water in the tank are pumped out during the usual fitting up of the hose to the water-main. In running order the engine weighs, with men and a full tank, some 6,380lb. The pump itself has three chambers. It forces the water through the axis of the reel into the rubber hose which carries the nozzle for producing jets of different sizes. The apparatus both on the engine and hose wagon is so arranged that a portion of the energy can be utilised for the lighting of arc or incandescent lamps for fires occurring at night. The whole set of apparatus is finished with an electrical ladder. This consists of a low truck upon which the large ladder in use in the department is hoisted almost horizontally by means of an inclined plane and a windlass. The total weight of this apparatus, inclusive of its crew, is 9,150lb. It is the heaviest of the pieces of fire material to which mechanical propulsion has been applied. By reason of the peculiar difficulties presented by the manœuvring of it, it became necessary to assure the perfect stability of the vehicle, especially in turning corners, while running at considerable speed, and this has been done so successfully that the electric ladder truck is more stable than horse-drawn ones. The electric energy necessary for the operation of the various kinds of apparatus is furnished by batteries of accumulators made by the Société Bouquet-Garcin-Schrive, of Neuilly. The batteries are suspended beneath the vehicle in specially made cases. The capacity of the accumulators is sufficient to allow a vehicle to run 36 miles at 12 miles per hour without requiring recharging.

A New Electrolytic Meter.—A patent has recently been taken out in America by Mr. T. A. Edison, the invention being a new type of electrolytic meter. The instrument is claimed to be very accurate, easily read, and not liable to get out of order. The base of the invention is an improved electrolytic cell which is easily standardised, and which at a constant temperature will always maintain a constant resistance, so that the rate of deposition is uniform. The cell has two electrodes of pure zinc immersed in a solution of zinc sulphate. In order to prevent any evaporation of the solution or any tendency to creep, the solution is covered with oil. Having obtained this cell, two or three are then connected round a relatively low resistance, whereby a minute but constant ratio of the current will affect the cells. There is then produced by the

Digitized by Google

deposition from one electrode to the other, and by positive mechanical devices, an easily-read accurate registration of the total current. To this end the movable electrodes of two cells are hung on the two ends of a beam supported on knife-edges or other relatively frictionless support, the electrical connections being such that while the metal is being deposited upon the movable electrode of one cell it will be stripped off of the movable electrode of the other cell, whereby the scale beam will tend to move downward toward the heavier movable electrode. If desired, however, a single cell may be employed, connected to one extremity of the scale beam, a counterweight being connected to the other extremity of it. The beam is connected with a retarding device, which opposes the stress exerted by either of the movable electrodes of the two cells on which the deposit is taking place. In this way the scale beam, under the effect of the depositing and stripping of the metal, will acquire an extremely slow movement in one direction or the other, the extent of such movement being constant, but its relative slowness depending upon the current influencing the cells. The oscillations of the scale beam actuate an escapement controlling a registering train, which operates a suitable pointer or pointers of a dial or dials. The connection between the scale beam and escapement is of a novel character, and is such that friction is so infinitely small as to be negligible. The registering train is driven either by a weight or spring, and since the release of the escapement takes place very infrequently, even when currents of considerable volume are influencing the cell or cells, it will be possible to obtain a sufficient fall of the relatively light weight as to require winding only during long intervals of time. In order that the oscillations of the scale beam may be produced, the current through the cells requires to be reversed at each tripping of the escapement, and an improved reversing switch is employed wherein only a single movable contact is required, this reversing switch being operated directly by the register train, and imposing no stress upon the scale beam. The elements of the meter are carried on an insulated board within the meter box having a glass front, through which the dials may be observed. When used in localities where low temperatures may be expected, it is desirable to employ a heating device, probably an incandescent lamp, brought into circuit by means of a thermostat if the temperature falls near the freezing point of the liquid in the cell. In order that changes in temperature, which affect the resistance of the cells, may not result in incorrect registration, there is interposed in series with the cells an ordinary compensating coil, the resistance of which changes inversely with that of the cells, whereby the resistance of the shunt, including the cells and the compensator, will be always maintained constant irrespective of changes in temperature.

Electricity on the Rand.—We have just received the *Transactions* of the American Institution of Electrical Engineers published for August and September of this year. In it we find a most interesting contribution by Mr. A. W. K. Peirce on the use of electricity in South Africa. Mr. Peirce has been for some years the leading electrical engineer of the Consolidated Goldfields of South Africa, and his *résumé* of the electrical work actually carried out on the Rand is most interesting. He refers, for instance, to the largest distribution system established up to the present on the Wittewaterrand. This mining district occupies a stretch of country 25 miles long and a few thousand feet wide. At the one end of this there are some coal mines, which produce a fair quality of bituminous coal, which makes it, of course, very convenient. A project was started for establishing a power plant at one of these coal mines, using the waste coal as it came out and distributing the power at high tension along the reef, and that was done. There is a plant of about 2,500 kw. installed capacity and stepping up to 10,000 volts, transmitting over a pole-line about 25 miles long. All along the reef branch lines are taken off at intervals wherever required, and then, stepping down to suitable voltage, it is used for other purposes, usually for motors. The suburban district of Johannesburg is lighted largely from this plant. As regards the troubles experienced in this distribution, the insulators have been not the least important. This Mr. Peirce attributes to the fact that these are not high-tension insulators, such as are used in the States. The insulators are instead rather larger than the ordinary porcelain types, without the necessary provision for providing the high insulation required by such high voltages. It appears that these insulators explode at times, as fragments are frequently found up to 40ft. and 60ft. away from the poles. This the author thinks is due to the moisture in a crack in the insulator being converted into steam. Iron poles are used throughout, as wooden poles are attacked by ants. The maximum load on the supply station up to the beginning of this year was 1,800 kw., which occurred during lighting hours. The day load varies from 1,000 kw. to 1,200 kw. The next largest plant belongs to the Consolidated Goldfields Company, and is also worked at 10,000 volts. It is found that the electrical distribution gives the mines great assistance when unexpected amounts of water are met with in the workings, as an additional motor and pump can be laid down much more quickly than any other system of pumping. This company uses three-wire rubber-insulated, lead-covered, and iron-armoured cables for the distribution. Mr. Peirce then proceeds to state that the direct-current installations were not found to be as satisfactory as three-phase plants with induction motors. This he attributes to the fact that the motors are not well looked after, and that the dampness underground causes considerable trouble with the direct-current armatures. Also, attempts have been made to run the direct-current motors at high voltages, going up to nearly 1,000 volts. One of the most interesting problems yet to be solved, according to Mr. Peirce, is the haulage for the deep-level mines. These will have shafts extending down from 8,000ft. to 10,000ft. A single hoist from this depth up to the surface is a somewhat difficult problem on account of the necessary great weight and strength of the rope. In fact, in order that the rope may support itself and the cage at the bottom of the shaft, the size to be employed is almost prohibitive. One solution of the problem is to wind in stretches, and Mr. Peirce suggests that about 3,000ft. per stretch would be a reasonable lift. He is now looking into the question as to the best means by which this can be done electrically, as either electricity or compressed air would have to be used on the lower stages. He then calls the attention of his readers to the fact that no experimental apparatus ought to be sent out to the Rand, because the issues at stake were much too great for this. For instance, suppose a manufacturer does undertake to make good any defects which may arise, or supply new machinery if the first is not satisfactory, it takes six months at least to get plant out and erected, and when a mine is reckoning on a profit of £30,000 per month it will be seen that the failure of the plant is a most serious matter. In fact, the maker's risk in guaranteeing is infinitely small compared with the risk incurred by the mine owners. From figures given by the author we gather that a large amount of hoisting plant will be required, and it is a problem to which our electrical engineers could well devote considerable attention.

THE PHILOSOPHY OF DYNAMO DESIGN.

(Specially contributed.)

(Continued from page 585.)

Commutators and Commutation.

It was shown in the first article that if any wire be made to cut a magnetic field that an E.M.F. will be created in this wire, and that if this wire has a closed outer circuit that a current varying inversely as the resistance of the whole circuit, and directly as the E.M.F., will flow through this circuit; and, further, that the E.M.F. obtaining at any instant will depend upon the number of lines of force cut during that particular element of time, so that, in other words, it may be said that the amount of current will vary inversely as the resistance, and directly as the number of lines cut per unit time. It was also shown (Fig. 2) that the direction in which this current will flow depends upon the direction of the motion of the wire relatively to the field, and also upon the direction of the flow of the lines of force in a plane which is at right angles both to the direction of the motion of the wire and also to its length.

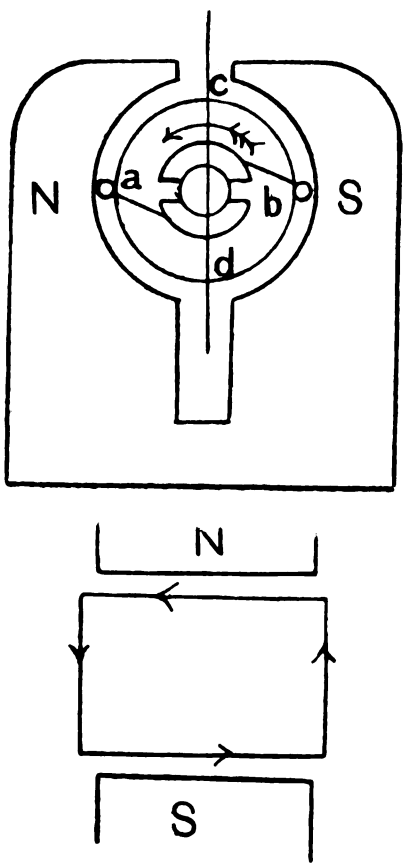

Fig. 10.

Fig. 10 represents a drum armature wound with a single complete coil, and it is assumed that each end of this coil is connected to a separate annular ring insulated from the other and also from the shaft upon which the two rings are mounted, and that the current is collected in any suitable manner from these rings. It will be seen from the plan that the two active lengths of the coil are in series with each other, the current flowing round the coil and through the outer circuit. If, now, a voltmeter were connected across these two rings, it would be seen that—assuming always a uniform speed—the maximum E.M.F. would be registered when the coil *a b* was in the position shown in the diagram, and that the E.M.F. gradually fell until the coil *a b* occupied the position *c d*, then gradually rose to its maximum when the coil had travelled through an angle of 180deg.—*i.e.*, when the positions of *a* and *b*, as shown in Fig. 10, were reversed—gradually falling again to zero, whilst the coil revolved through a further angle of 90deg, and rose once more to its maximum as it completed the full cycle, and reached its first position. If a current indicator had also been inserted, it would have been noted that while *a* travelled from *c* to *d* the current was flowing in one direction, but while it revolved from *d* to *c* the current was flowing in the opposite direction. This is only what would be anticipated from an application of the three fundamental principles. The lines of force flow—we may conveniently assume for the present—in straight lines across the armature core from one polar face to the other, and they have over all this area a uniform density—*i.e.*, in

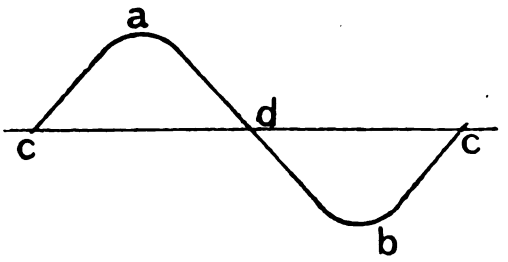

Fig. 11.

any square inch, or other unit area, taken in a plane normal to the flow, the number of lines passing is equal to that in any other square inch; and as the speed of revolution is uniform, the angle passed through in unit time by the coil is always the same, but the number of lines cut during this unit time will constantly vary, for while with the coil at *a* it is cutting straight across the magnetic lines, at *c* it is sliding, as it were, between them and not cutting any. If a large number of readings were taken and were marked on a chart, so as to show the E.M.F. produced at every instant, it would be found that the *locus* of these points would be a true sinusoidal curve as in Fig. 11, where the part of the curve above the line represents a current flowing in one direction, and the part below the line represents the current flowing in the opposite direction. It will be readily seen that this curve must be a true sine curve, for we have formerly stated that there will be uniform density of field in the plane *c d* (Fig. 10), which is parallel with the axis of the shaft, and at right angles to the direction of flow of the lines of force; and in order to cut a uniform number of lines per unit time it would, therefore, be necessary for the coil to travel a uniform length along *c d* per unit time, but since the coil travels through an equal angle per unit time, it is an easy mathematical proof to show that the distance traversed by the coil along *c d* is proportionate to the difference in the sines of the angles which lie between the lines, *c o*, *a o*, where *a* is the position which the revolving coil occupies at the end of equal intervals of unit time.

If the two annular rings be taken off and one ring be substituted, this ring being divided into halves along a plane parallel to the axis of the shaft, and if the two halves be insulated from each other and from the shaft we get an elementary commutator; if, then, the two ends of the coil be connected one to each of these commutator segments, and the brushes are so arranged that they pass from one section of the commutator to the other when the coil is in the position, *c d*, sliding through the lines, the current will in the outer circuit attain a maximum and minimum effect, but will always flow in the same direction,

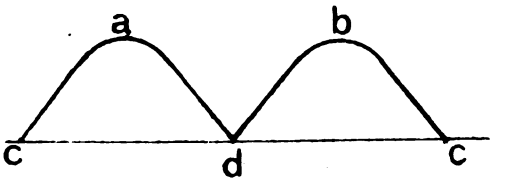

Fig. 12.

and it is then said to be commutated from an alternating to a direct current. It is worth noticing here that, with the single exception of homopolar dynamos, in all modern dynamos the current is generated as an alternating current, but in a direct-current dynamo it is rectified by the interaction of the commutator and the brushes before passing to the outer circuit. If, as before, periodical readings be taken of the E.M.F., and a curve representing this at any instant be drawn (Fig. 12), it will be found similar to the curve shown in Fig. 11, only

Digitized by Google

with the bottom part of the curve doubled over the datum line, showing that the current in the outer circuit flows always in the same direction, though the E.M.F. passes through a cycle of values.

If now, in place of a single coil being wound round the armature core, the coil be wrapped round twice before the two ends are connected to the commutator, it is evident that the four active lengths will all be in series with each other, and that if the speed be the same as before, the E.M.F. produced will be double that previously obtained; if, now, another voltmeter curve be obtained, the only difference will be that the length of the ordinates will be increased, the E.M.F. will still vary uniformly from zero to its maximum and back again to zero continuously.

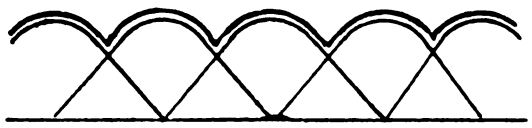

FIG. 13.

If, now, this extra coil be wound as a separate coil at right angles to the first, but in series with it, and a four-part commutator is made, each coil will only generate half the E.M.F. of the double coil, and as the coils are at right angles to each other, one coil will be cutting across the largest number of lines of force per unit time, while the other coil is cutting none; hence one will have its maximum value when the second has its zero value, and the first will gradually decrease to its zero value while the second is equally increasing to its maximum value, and we shall get two sine curves, one due to each coil, overlapping each other, as in Fig. 13, the resultant curve of the induced E.M.F. being shown for any instant by the heavy curve. It will be noticed that this resultant curve is very far from being a straight line, and that there will consequently be very great fluctuations in the induced E.M.F. In order to obtain a less fluctuating resultant E.M.F., the number of the coils and of the commutator segments must be increased, and these coils must be arranged symmetrically round the armature core, while the commutator segments must be equal in width and have a uniform pitch. It has been shown that with a two-coil armature wound at right angles, one coil must be passing through its position of zero value while the other is passing through its position of maximum value, and that hence the maximum E.M.F. will only be that which one coil would generate—although the amount of the fluctuations is halved. With an eight, sixteen, or other larger number of coils, more will lie in a strong field than in a neutral field, as the angle of embrace of the pole-pieces is usually larger than the angle of non-embrace. Consequently, not

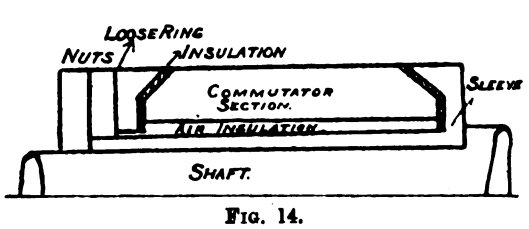

FIG. 14.

only will the amount of fluctuation with a large number of commutator segments and coils be considerably less, but the average E.M.F. will be higher. It has been found that for any number of coils above four, the average E.M.F. is about 0·63 of what the maximum E.M.F. would be were all the coils wound as one continuous coil and connected to a two-part commutator. The amount of fluctuation in the E.M.F. varies inversely as the number of commutator parts, but after a certain limit there is little advantage in further diminishing the fluctuations, as they are not appreciable whether the current be used for lighting or other purposes.

It has been pointed out that the various commutator segments must be insulated from each other, and also from the shaft, and although the mechanical construction of the commutator cannot be said to be in any way directly ruled by our fundamental principles, yet the difference in the running which a well-designed and well-built commutator makes to any dynamo is so great that it is most important that the student should have a sound knowledge not only of the function of the commutator, but also of the various stresses to which it is subjected. To begin with, we speak of the mechanical construction of the commutator, and yet at the same time, owing to its most unmechanical construction, it is generally the weakest part of any machine, while, in addition, the majority of the difficulties which arise in the design of a dynamo are those due to the requirements of either sparkless commutation, or fixity of lead—both commutator matters; and, further, after the machine is designed, built, and fixed, the commutator is the one part of the machine which receives the worst treatment: either the brushes are held down with too great a tension, or else, often, they are never readjusted, so that imperfect contact is made. Sometimes the commutator is left unlubricated and untouched; at other times, owing to the ignorance of the dynamo tender, it is so saturated with grease and oil that it collects all the dirt and filth of the engine-house, while often in private installations sparking is permitted to take place because the brush lead is not altered with the variations of load. So that we may sum up the question of the commutator thus: its mechanical construction is very weak and unsound at the best, it is concerned in the most difficult operation in the generation of a direct current—viz., the rectification of the current—and in actual work it too often receives only scant consideration and attention.

It has been shown that the various commutator segments must be efficiently insulated, not only from each other, but also from the shaft. In order to hold the commutator in position two end flanges are necessary, as shown in Fig. 14;

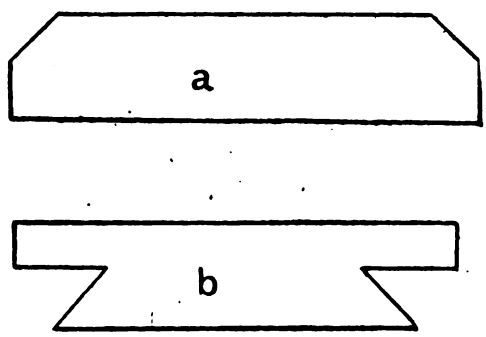

FIG. 15.

one of these is keyed tightly to the shaft, whilst the other is loose, and is forced into its position by means of a suitable nut, or bolt and nuts, tieing the two flanges together. In small machines it is usual to cast the fixed flange to a sleeve, which is keyed to the shaft, and which is screwed at the other end to receive the tightening nut holding the loose flange in position. Fig. 15 represents two sample types of commutator segments; *a* shows one in which the top corners are cut away to enable the end flanges to secure a good grip, while for the *b* type the end flanges are made with a horizontal V, which fits in a groove turned in the segments. No great difficulty would arise in building up a strong, sound commutator on such a principle, if it were possible to obtain a metal which was a good non-conductor of electricity, but as this is an impossibility, and it has been found impracticable to make a strong, substantial sleeve, with its necessary flanges, of any insulating substance, a loose sleeve or ring of some non-conducting material has to be inserted between the flange and the commutator, and this causes all the mechanical difficulty. The insulation of the various sections from each other is usually effected by means of thin slabs of pure mica, and that of the commutator from the sleeve or shaft by air only, the depth of the section being so designed as to leave such an air space between them and the shaft as shall prevent the current from arcing across in any way. The end insulation rings are now usually made of micanite, although other substances, such as red fibre, vulcanite, presspahn, have been and are still used. The peripheral speed of a modern commutator may be anything from 1,500ft. to 2,500ft. per minute, which is very high for such a loosely constructed article, and it is evident that the centrifugal force, especially as the mass is considerable, tending to cause the component parts of the

Digitized by Google

commutator to fly apart will assume a great magnitude. If, now, the commutator is in any way slack, or any one bar is not firmly gripped, this bar will fly outwards as far as possible, and as the whole commutator is held together by the wedging of the bars against each other, the shifting of one bar even to a slight extent will loosen the whole structure, and some bars will rise considerably higher than the others, and the necessary smooth and even surface of the commutator will be entirely destroyed. If, however, the commutator be well tightened up, it may be found that the bars have too small a cross-sectional area to carry the maximum current without heating considerably, or the friction of the brushes may cause undue heating, and this increase in temperature will cause the bars to expand, and so press more tightly into the insulating end rings, which, owing to their nature,

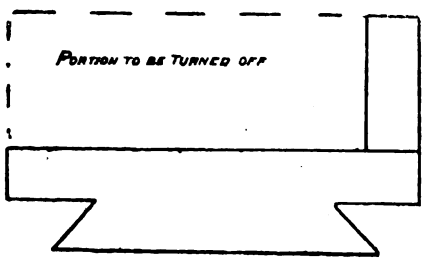

FIG. 16.

must have a yielding character. Upon cooling, the bars will contract and become slack, when the same result as that above described as due to a loosely-conducted commutator, will be obtained. The only method of securing a sound commutator is to arrange the cross-sectional area of such a size that, even allowing liberally for the heating due to friction, the rise in temperature of the whole commutator, after a prolonged run with full load, shall only be slight; a certain definite rise of temperature is often given in specifications for the armature, while no mention is made of any limiting value for the rise of the commutator—a matter which is of considerably more importance. After the cross-sectional area has been made large enough to fulfil the above requirements, the commutator should be built up and tightened in a lathe, and then, while being revolved, heated equally all over by means of a gas stove or other arrangement to some 10deg. or 15deg. F. higher than it is calculated the temperature will ever be in practice. It should then be allowed to cool to the temperature of the surrounding air, when it should

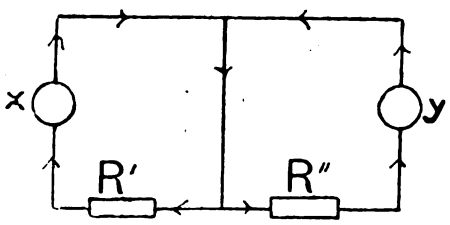

FIG. 17.

be again tightened up, and this process should be repeated three or four times. After being finally tightened up, the nut holding the loose flanges in position should be pinned or otherwise secured to the shaft to prevent it at any time working loose. If any type of section similar to *b* (Fig. 15) be employed, care must be taken to see that the sharp edges of the V's of all the flanges are cut away, otherwise there is a great possibility of these V's cutting through the insulation as the loose flange is tightened up; also great precaution must be taken to get rid of any dust in the commutator, which might cause a short-circuit between two bars.

The reason why such great care must be taken to prevent any bar from rising above its fellows is, that in order to obtain the best results the brushes are only held very lightly on the commutator, and with the high peripheral speed a risen bar would momentarily throw the brushes off the commutator, with consequent sparking. The section where the brushes were thrown off would become pitted and burnt, and the section upon which the brushes lighted again would also become worn away; flats would then be developed at these two points, and until these were turned out and the commutator tightened up, it would be quite impossible to run the machine without a great amount of disastrous sparking, which, if allowed to continue, would soon destroy the whole commutator. Flats will also be formed if any of the bars are softer than the others, and this prohibits the use of cast copper sections, as it is impossible, especially with copper, to guarantee that any two castings shall have the same degree of hardness; makers are therefore compelled to use either drop forged or rolled copper sections. The disadvantage of the latter is that usually it is necessary to have a lug of greater or less length attached to each section, and, as will be seen from Fig. 16, it would be a very costly matter if the bars were obtained of such a depth

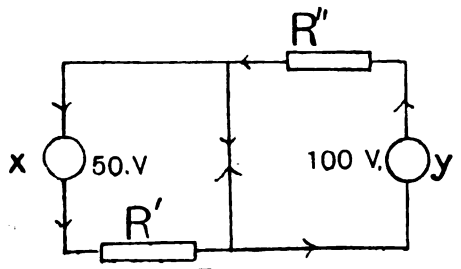

FIG. 18.

as would permit of their being turned down to leave a lug some 6in. or more long on each section, while the cost in labour of so turning them down would be very considerable. Hence the usual practice is to mill a slot in the end of each segment and let in a separate lug. This may be of cast or strip metal, according to the designer's fancy, but it must be firmly fixed. Preferably it should be brazed and riveted, as a loose or imperfect connection here or in any part of the armature will give rise to very heavy sparking when the machine is working.

The writer does not profess to have given every method which has been adopted for building up a commutator, but rather to have pointed out the main considerations which must be fulfilled in every design, whether for large or small dynamos, if successful running is anticipated. It is advisable to design the commutator to have such a length that the brushes may be staggered—*i.e.*, the positive and negative brushes should not trace out the same annular path, but rather overlap each other—so that should there be any tendency towards grooving, the

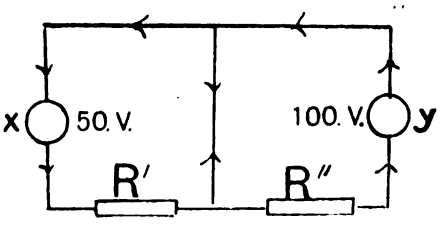

FIG. 19.

negative brushes may be so placed as to wear away the ridges which would be formed between the positive brushes, and *vice versâ*. It is also important that at least two brushes should be placed on each line of every machine, however small, so that, if necessary, one brush of any line may be removed or adjusted without interrupting the flow of the current while the machine is running. If sparking sets up at the brushes of a machine on which the commutator has just been turned true, in a very short time the surface of the commutator becomes badly worn, whereas if a machine runs for any length of time without sparking, a hard bronzy glaze is formed all over the commutator, which resists wearing away by sparking to a very great extent. The writer has found that if a machine be run with the brushes down on open circuit, but with the shunt excited from the armature, for two or three days when the machine is put down this glaze will be formed, and as any machine can be run without sparking on open load this glaze can always be produced. If, then, slight sparking does occur with full load, it will not be so injurious to the commutator as it would be were it not protected by this glaze.

Digitized by Google

Having dealt thus far with the construction and design of the commutator, we must now turn our attention to its function and to the theory of commutation. It was pointed out in the first article that an extension of Ohm's law, that $C = \frac{E}{R}$ was that if a current had several paths open for its flow it would be divided amongst them inversely as the resistance of the various paths, and it will be readily seen from Fig. 17 that if there are two different circuits having a common path during part of their circuits they will augment each other and flow down the same path together. It will also be seen from Fig. 18 that if the two currents oppose each other in this path, if they are equal in quantity, no current will flow down, but each will take up the work of the other. If the currents are not equal, only the amount of current equal to the difference in their values will flow along this path, and this will hold good whatever be the E.M.F.'s of the two currents, whether the same or not. For assume in Fig. 18 that x and y are two generators of electricity having no internal resistance, and that the external circuits apart from the resistances marked R′ and R″ have no resistance, that x generates a current at a pressure of 50 volts, and y a current at a pressure of 100 volts, and, further, that the directions

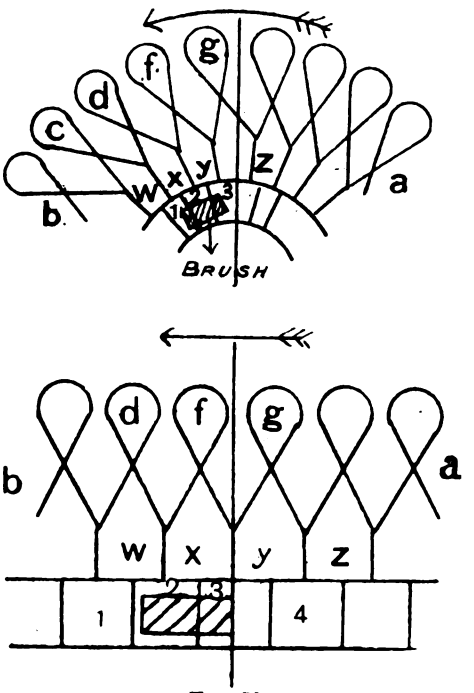

FIG. 20.

of flow in both circuits are those shown by the arrow heads. First, let us assume further that R′ = 10 and R″ = 20, then the current flowing round D C B A, if C F E B were taken away, would be five amperes, and that flowing round E B C F would also be five amperes were C D A B obliterated. At the positive side of x we have a pressure of 50 volts, which is maintained until the resistance R′ is reached; during the rest of the path the current is at zero potential. The same is the case with the current due to y. Now, if the path B C be removed there is a closed circuit still remaining—viz., E A D F—and the two generators are in series, and the conditions named above still hold good—viz., from R″ to x there is zero potential, and from R′ to y there is zero potential. There will, however, be a current flowing round the circuit, for considering the current to start at y, when it arrives with a zero potential at x its pressure will be raised to 50 volts to enable it to flow through R′ and thence into y. Hence, as in any case there will be zero potential at B C, the addition or omission of this path will make no difference, as no current will flow along it, and it may be said that x receives the current flowing from y, and y that flowing from x.

Let us now assume that R′ = 10 and R″ = 10. In this case we shall have a current of five amperes due to x and one of 10 amperes due to y. If B C is removed, we shall have at B zero potential of the current from y, and at C zero potential of the current from x. The y current upon reaching x will be boosted up to 50 volts, but since $C = \frac{E}{R''}$ and R′ = 10, only five amperes can pass through, and the other five will be blocked at x. If, however, the path B C be now inserted, these five amperes can flow down this path of no resistance to the negative side of y, and we shall have the whole of the x current flowing to y—half of the y current flowing to x to compensate for the x current which is flowing to y, while the other half of the y current will flow along the path B C.

If the two resistances be arranged as in Fig. 20, where x, y, R′, R″ have all the same values as before, we have a slightly different state of affairs. If B C be removed, there is a potential of 100 all the way from the positive of y to the negative of x, when the current is boosted up another 50 volts, and from the positive of x to R′ there is a potential of 150 volts. Now, the total resistance in the circuit is R′ + R″ = 10 + 10 = 20, which, since $C = \frac{E}{R'}$ will allow the passage of a current of 7·5 amperes. Hence, since E = C R, the fall of the potential due to R will be 10 × 7·5 = 75 volts, and we shall have a potential of 75 along the path between R′ and R″, and along the path from R′ to the negative of y a zero potential. If, now, the path B C be inserted, we shall still have a potential of 100 volts between y and x, and one of 150 between x and R′, and if 7·5 amperes flow through this resistance we should get a potential of 75 between R′ and C due to this current, but owing to the path B C having no resistance, there will be the same potential at C as at B—viz, 100 due to the y current. Hence along R′ C there will be a potential of 75 volts in a forward direction and of 100 in a backward direction, so that in addition to the resistance R′ there will be the extra resistance due to this back E.M.F. The condition which must be fulfilled is that the potential at C shall be equal for both the x and y currents—*i.e.*, the potential of the x current shall only fall 50 volts—and since E = C R′, we getting substituting known values, 10 C = 50, or C = 5. Consequently only five amperes can flow along the path B A D C, and we obtain the same result as before—viz., all the x current flows to y, half the y current flows into x to compensate for the x current flowing into y, and the other half flows down B C. It could be easily shown that the current would be similarly divided if it flowed the opposite way—*i.e.*, if the positive and negative sides of x and y were both reversed.

(To be continued.)

MISTAKES IN THE RATING OF INCANDESCENT LAMPS.*

BY ARTHUR J. ROWLAND, MEMBER.

(Concluded from page 564.)

It is interesting to notice, in these plots of illumination, that after the 45deg. ray is passed the value of all types of filaments is about the same; and it should be noted that the illumination procured is very small. An illumination of one-tenth of a candle-foot, for example, is that which one receives on a piece of paper held vertically more than 3ft. from an ordinary candle. Such light as passes out from a lamp in directions nearly horizontal or above the horizontal plane is useless except it is reflected back to the surfaces to be lighted or contributes to the general illumination by dispelling the gloom of the upper parts of a room and by giving a diffused character to the light. While it has such value, it is rarely that one can afford to use much light this way. If light is useful after reflection, it must travel in long paths, so that even if it reaches points where it is useful, so little illumination is produced that direct light is much the best. A very white surface will not reflect more than 85 per cent. of the light which strikes it, while dark walls and ceilings and hangings reflect almost no light at all. The item of reflected light is then one of very uncertain amount at most. Take a

* Paper read before the Franklin Institute.

Digitized by Google

room in which the ceiling is only 12ft. high, in which a 16-c.p. lamp hangs 4ft. from the ceiling, and one finds that no rays from any lamp now made, passing out to reach the ceiling or wall above the horizontal plane through the lamp, will give an illumination of as much as ·05 candle-foot on a surface 5ft. below the lamp, even on the assumption that the ceiling and wall are the best possible reflectors.

Influence of Filament Form on Candle-Power.—A number of interesting matters connected with the distribution of light from lamps having filaments of the different types are shown in Figs. 4 to 8, inclusive. Each figure gives the results from a test of one lamp—a lamp chosen to represent the type because it was truly representative mechanically, and by check against other lamps was found to be representative in light distribution. The rough sketch of the lamp on each figure shows very nearly the actual shape of the filament whose candle-power was measured. The left-hand sketch shows the lamp as it stood for measuring the horizontal candle-power at 0deg. and the right-hand figure at 90deg. In all the candle-power diagrams distance out radially from the centre of the diagram to the heavy curve giving the candle-power in that particular radial direction. Thus, in the curve of horizontal distribution, if the lamp stood with axis vertical and one went around the lamp taking candle-power of the light given in the direction toward him as he went on, these values of candle-power have been recorded and can be read off on the diagrams up to the heavy line. The same interpretation holds for the curves of vertical candle-power at the right of the figures.

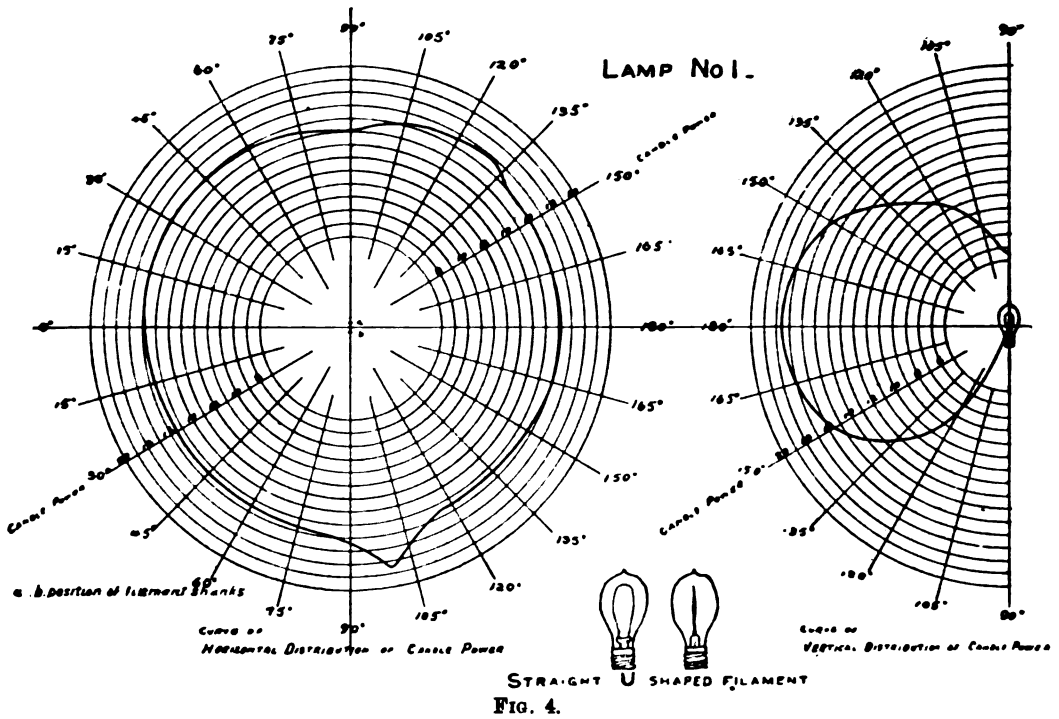

FIG. 4.

All the lamps were kept at the voltage at which they give 16 c.p. on the basis of the manufacturer's rating. In the curves of horizontal distribution we see that lamp No. 1 with the straight U-shaped filament is quite uniform in candle-power all around. The candle-power distribution of the long curl anchored filament (lamp No. 3) and the double filament (lamp No. 4) are somewhat similar. The irregularity of the curves for lamps Nos. 2 and 5, coil filament types, is great. This is always distinctive of lamps of the sort. The striking irregularity at one point of the curve for lamp No. 2 is not abnormal.

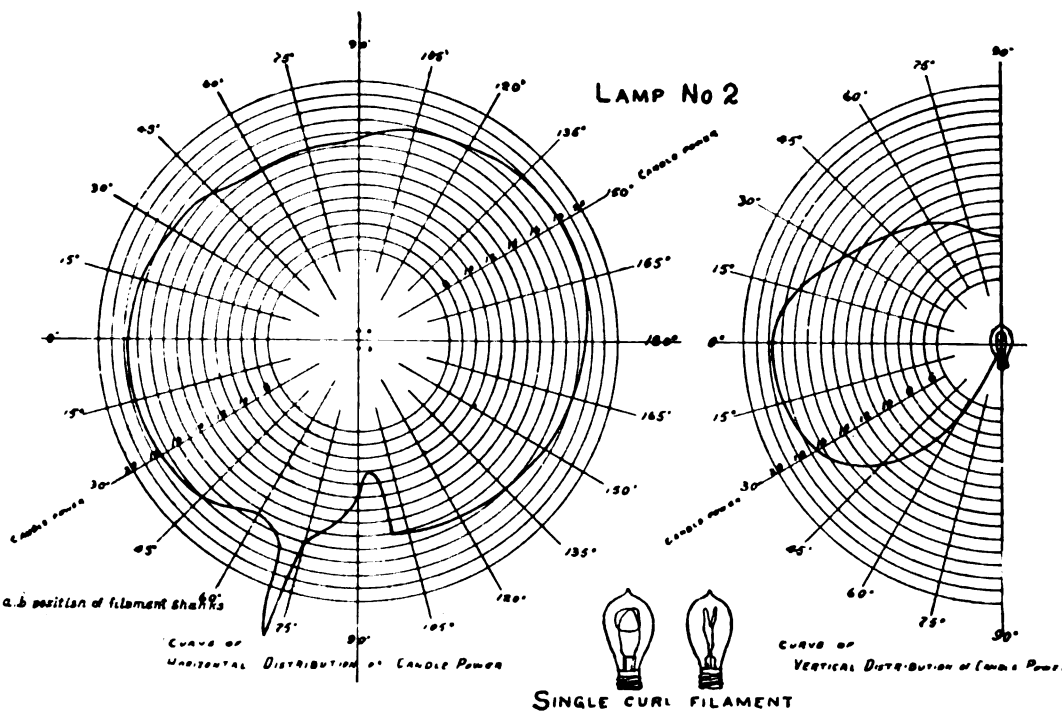

FIG. 5.

Digitized by Google

There are often two such breaks, one on each side of the lamp. The cause of this irregularity may be due to complex reflection and refraction of light due to varying thickness or curvature of the glass enclosure. It has not been investigated, I think. Since the manufacturer's rating is on the average or mean horizontal candle-power a lamp gives, the more uniform the candle-power curve of horizontal distribution the more nearly perfect a lamp might be considered, I suppose. At least, this seems to explain the design of the most recent filament forms. But by far the most important distribution is that in a vertical plane. Here the great differences in candle-power procured from various filament forms show best. Look at the curves.

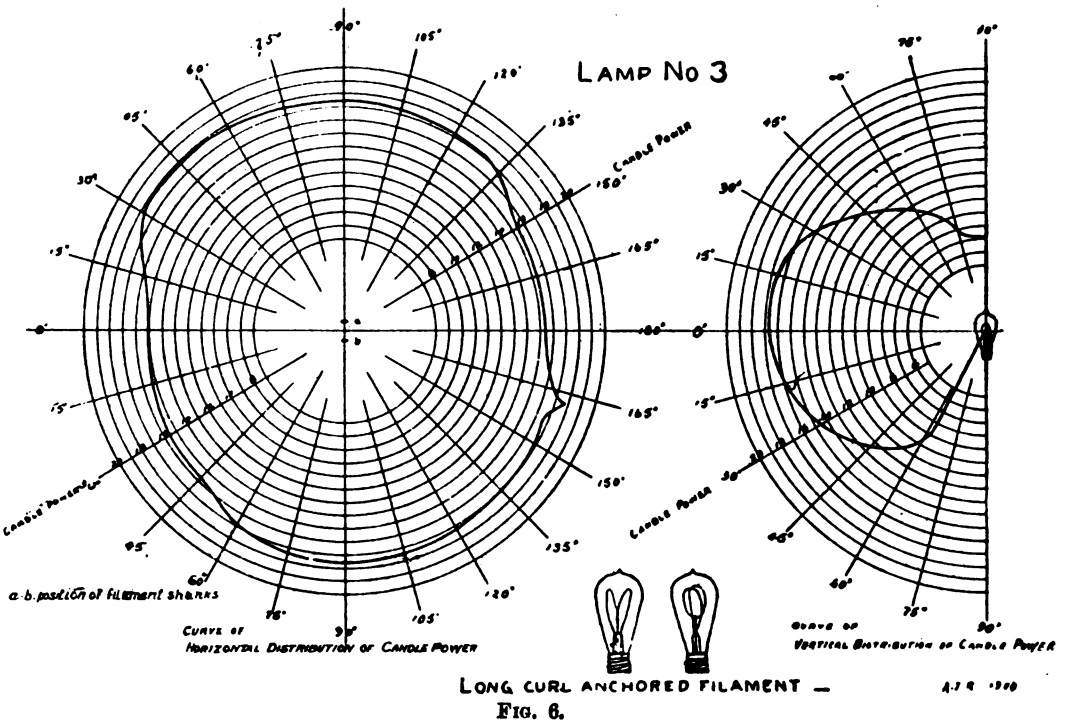

FIG. 6.

Lamps Nos. 1, 3, 4 are dreadfully deficient in light from the tipped end, and the candle-power of each falls off very rapidly as the 90deg. angle is approached.

How especially in this true of lamp No. 4, which, just as one comes to the direction from which the light is most important (between 75deg. and 90deg. at the tipped end), drops the candle-power down to less than five units. Most of the lamps, curiously enough, give most light in zones beyond the horizontal toward the base, where its usefulness is very problematical. This is true, too, of lamp No. 5, which maintains the candle-power it gives so well out toward the tipped end. It sends a good deal of light toward the base, but if we have a good light where it is useful, we must not criticise too severely the delivery of light where it has no especial value. The effect of the omission of the sealed-off tip on this lamp in helping up the candle-power at the end is well shown in the curve of vertical distribution for lamp No. 5, where from 75deg. to 90deg. the candle-power keeps up. This is due partly to the way the loops of the filament are spread, and partly to the omission of the tip.

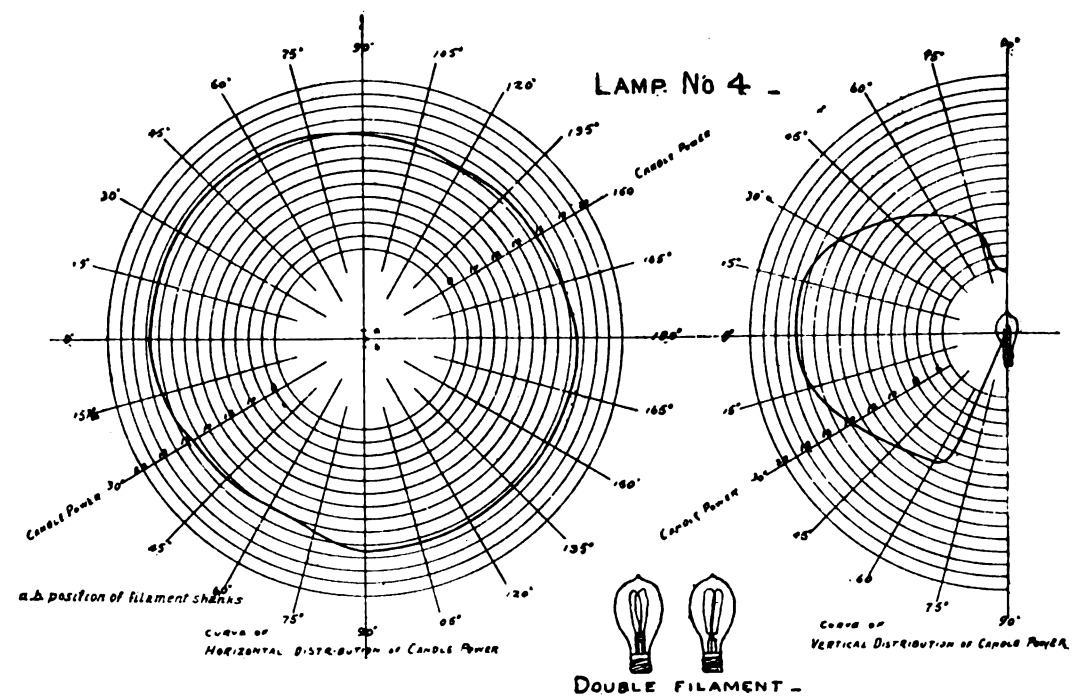

FIG. 7.

What is a 16-c.p. Incandescent Lamp?—It does not take much consideration of these curves to satisfy one that a 16-c.p. lamp is not necessarily one which gives 16 c.p. where this much light is wanted. The candle-power of incandescent lamps is determined really in a very empirical and arbitrary fashion. Most people seem to think it is as surely known as the watts used, and is as readily measured. But really it is about as vague and elusive a value as the

Digitized by Google

candle-power of an arc lamp, for which it has facetiously been said that it gives 2,000 c.p. because at any street corner it delivers 500 c.p. in each of the four directions. The common method of measuring candle-power in use by the manufacturers of incandescent lamps is to spin them at 180 revolutions per minute on a vertical axis and measure the average horizontal candle-power by a single reading. How this comes to be accepted as satisfactory, and what the status of candle-power measurement of incandescent lamps is, will be worth a little consideration right here.

When incandescent lamps first became commercial, they were put into competition with gas lights, and were made so they would measure 16 c.p. when placed in a photometer, precisely as gas lights had to be placed—base down, and the old U-shaped filament with a plane through the shanks of the U perpendicular to the photometer bar. Indeed, since photometers (except for purely scientific investigations) were used only for measuring the candle-power of illuminating gas, these very photometers were used for the incandescent lamps; and methods for gas photometry were adopted as far as possible into their candle-power measurement. It was soon clear that some more complete sort of measurement ought to be made, and in 1885, in connection with important tests of incandescent lamps for their economic value, probably the most elaborate tests ever made, the Franklin Institute adopted a method of measuring the mean spherical candle-power which was really an empirical or arbitrary one, but gave as a result a candle-power value quite nearly the true average of all measurements when the lamp was viewed from all possible directions.*

The measurement of the mean spherical candle-power by the Franklin Institute method requires that at least between 40 and 50 measurements on the photometer be made, and the average of 38 determinations is taken to get the result. About two hours' time for two operators with a well-equipped photometer laboratory is required for the measurement of one incandescent lamp, while the apparatus required, as supplied by instrument makers, is defective, in that it does not enable satisfactory measurements of the light radiated in directions near the lamp base to be made. While, then, this method came near giving the real average candle-power of a lamp, it could not well be used by lamp manufacturers in rating their product, nor was it. Most of them rated their lamps by the candle-power measured when the lamp stands vertically with base downwards and the bar of the photometer points to some selected side of the lamp. Some attempts were made to use a constant number, by which this reading of candle-power might be multiplied to give the mean spherical candle-power for a given type of lamp, but without success in commercial usage.

In recent years lamps have been measured by their mean horizontal candle-power and so rated. To save time, the manufacturer has lamps standing in the position already described, but has them rotating when the candle-power is measured; 180 revolutions per minute is a common speed, and the voltage marked on the label is that required to give 16 c.p. when the lamp is so rotating. The user who checks the manufacturer's product as it is delivered to him must perforce use the same method.

The National Electric Light Convention, not satisfied with the uncertainty of the methods in use, and in order to procure uniformity of standards and practice in rating lamps, appointed a committee, who made a report at the convention in June, 1897, in which they say that the mean spherical candle-power is the only proper and fair value to consider in comparing lamps. The practical measurement of this is so difficult, however, that a simpler method was recommended whereby the average luminous output of the lamp might be measured. The proposed measurement was to be taken "in the direction inclined 45deg. to the axis of the lamp, while the lamp is revolving upon its axis, the distance of the lamp from the photometric screen to be regarded as the distance between the centre of the axis of its bulb and the screen. This will furnish a fair approximation to the mean spherical candle-power, and reduce the amount of labour in measurement to the minimum." Two revolutions per second or 120 revolutions per minute was recommended as a speed of rotation.

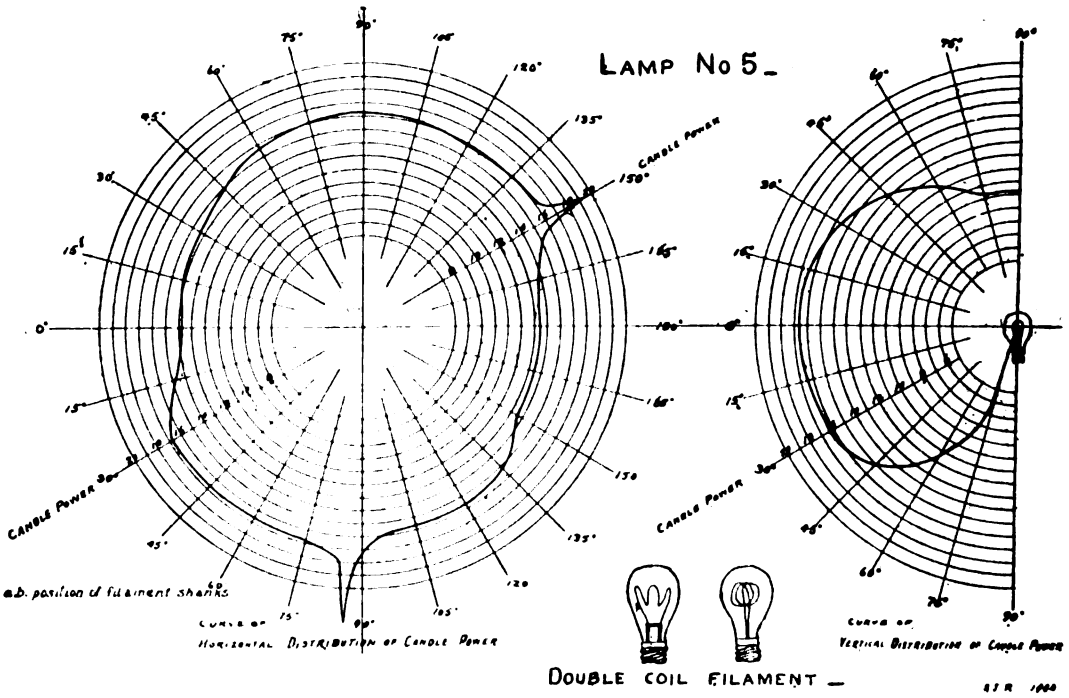

FIG. 8.

A year later, in June, 1898, the same committee made a further report telling of tests made, confirming the committee's suggestion of measurement at 45deg. of inclination, and making the proper speed 200 to 250 revolutions per minute. The committee was continued and made another report at the last meeting of the convention, but altogether on other phases of the subject—photometers, standards of candle-power, etc. Here the matter rests. In spite of the official adoption of the report by the convention, manufacturers continue to rate their lamps by a measurement of mean horizontal candle-power with the lamps in rotation at 180 revolutions per minute. There is no photometric apparatus made which can be satisfactorily and continuously used for the measurement adopted by the National Electric Light Association, and if there were, the indefiniteness of the conclusions reached leaves much to be desired.

* The influence of candle-power measurements of gas upon similar measurements of incandescent lamps is well shown by the fact that the photometer expert of the Franklin Institute committee was Dr. Ward, the Philadelphia gaslight photometric expert.

TABLE A.—Candle-Power of Lamps with Different Forms of Filaments.

Candle-power taken.	Candle-power. Single U shaped filament	Single curl filament	Long curl anchored filament	Double filament	Double-coil filament
(a) At 180 revs. with axis vertical	16	16	16	16	16
(b) Mean horizontal (standard method)	15·8	16·2	16 6	16 0	15 72
(c) Mean horizontal (from plotted values)	16·0	16·7	16·7	16 1	15·6
(d) Mean spherical (standard method)	12·7	13·5	13·75	13·2	13·8
(e) Mean with axis at 45deg.	10·5	12 0	11·7	12 0	14·0
(f) Mean hemispherical	14·3	14 5	14·6	14·0	14·5
(g) Mean within 30deg. from tip	8·7	10·3	8·7	7·9	10·9
(h) From the tip	5·7	8·35	7 05	4·8	10·1

In Table A, I have set down a number of candle-power values for each of the five lamps of which some data was given in Figs. 4 to 8 inclusive. Each of these gives a value of candle-power by which the lamp might be called. The values were procured as follows: A lamp was set at 16 c.p. when rotating at 180 revolutions per minute with the lamp axis vertical, in the common arbitrary method, and for all measurements involved in the other tabulated values was held at that voltage. Values in line *b* were determined by taking the average of 12 readings as the lamp is turned, beginning with its standard position and at every succeeding 30deg. Values in line *c* are computed from the curves in Figs. 4 to 8 which take account of all horizontal candle-power variations. The line of mean spherical candle-powers is computed by the Franklin Institute method. Notice how much less the real average is than the rated candle-power in each case, and how this average compares with the rated value for each type of filament. Line *e* gives the candle-power these lamps should have been marked if rated by the National Electric Light Association's standard. The readings are not by a rotating socket, but averaged from readings made individually from the lamps tilted at the right angle. It will be noted that this agrees poorly with the value of mean spherical candle-power, and bears no easy numerical relation to it. Line *f* of the mean hemispherical candle-power is to be compared with the spherical candle-power values, and this in turn with the line *g*, in which average candle-power is included every ray of really useful light. Line *h* is set down for comparison and to mention later. With such an array of candle-power values for each lamp, what is its candle-power?

What should a 16 c.p. Lamp be?—Earlier it has been pretty thoroughly explained that the only sensible candle-power by which to call an incandescent lamp, is that which is useful in producing illumination at desired points. Such a method has never been used in marking incandescent lamps for sale. It is strange how precedent binds us in everything we do. Here in the matter of incandescent lamp candle-power we are all tied to methods of designation which look back to photometric methods used for gas-burners. True mean spherical candle-power and rotation methods are distinctively electrical, but they first came to be of importance because incandescent lamps are so commonly placed in positions impossible to gas-burners, and the rotation methods are used simply to save time in measurement, one reading taking the place of a dozen. It has already been explained that mean spherical candle-power is an impossible measurement for commercial purposes. Rotation methods are poor, too. Not only does the speed of rotation affect the result procured, but some of the best modern lamps produce such a flicker at the car of the photometer when rotated at standard speed (180 revolutions) that not only is the making of an observation most trying to the eyes, but the observer can only make a rough guess for the position of his screen when a balance is obtained. A recent suggestion to choose such a speed for each lamp as just removes the flicker is impracticable also, for not only does it require an adjustment of speed with different lamps, but with many filaments high speed of rotation distorts the filament or even throws it against the glass, due to centrifugal forces brought into operation by the high speed.

What more rational, then, than to measure the lamp's candle-power looking in at the end? It is the light coming from the end which we make use of—which we are interested in. Then this is the light to measure, and that by which the lamp should be rated. Lamps measured thus are as comparable with each other as lamps measured any other way. The apparatus required to make the measurement would be very simple, for no rotating device would be required, and the lamp need only be inserted in the socket without any care as to which side comes uppermost when its candle-power is determined, since the candle-power must always be read the same. Thus, readings of different observers would agree without respect to anything involved in the measurement, except the standards used and the personal element, which never can be eliminated. Such a radical change of method, however sensible the change, could not be made without the sanction and support of some of the large associations of electrical engineers. In the meantime, however, for eventually this method must certainly come to be used, all lamp users, should in addition to a measurement of candle power in the conventional way to check up the lamps purchased, take a reading of the useful light out from the tip.

A 16-c.p. lamp should be one giving 16 c p. from the tipped end. The horizontal candle-power might be considerably less and be irregular in different directions without altering the real value of the lamp. An ideal 16-c.p. lamp would perhaps be one which measures 16 c.p. from the tipped end, had 16 c.p. as the mean horizontal candle-power, and was of nearly 16 c.p. mean spherical. Such a lamp could be turned into any position in an electrolier and still give an illumination equally as good as before and as well distributed.

In most lighting, also, the end of the lamp which has been called the tipped end all along should be tipless. Hold a piece of white paper below an ordinary tipped lamp hung with the tip down, as it commonly is, and the reason is unnecessary to state. Variations in thickness of glass and shadow cast by the tip make lines of light and shade that spoil all real value of light procured.

Since the making of such lamps as these is doubtless but a choice of filament form and arrangement, let us hope it will not be long until there are some ideal lamps available commercially.

TABLE B.—Watts per Candle-Power of 16-c.p. Incandescent Lamps on Basis of Different Candle-Power Ratings.

Watts based on candle-power as stated.	Watts per candle-power. Single U shaped filament	Single curl filament	Long curl anchored filament	Double filament	Double-coil filament
(k) At 180 revs. with axis vertical	3·5	3·5	3 5	3 5	3 5
(l) Mean horizontal (standard method)	3·54	3·45	3 37	3·50	3 56
(m) Mean with axis at 45deg.	5 33	4 66	4·79	4 66	4 00
(n) Mean spherical	4·40	4·15	4·07	4 23	4·07
(o) Mean hemispherical	3·92	3·86	3 83	4·00	3·86
(p) Mean within 30deg. of tip	6·44	5 44	6·44	7 09	5·14
(q) From the tip	9 82	6 71	7 95	11 70	5·54

What is a 3·5-watt Lamp?—So far no word as to the efficiency of lamps has been said. It does not directly affect the candle-power nor distribution of candle-power. All the lamps mentioned above, for instance, were 3 5-watt 16-c.p. lamps. But why are they 3·5 watts per candle-power? Each lamp used burned with a consumption of 56 watts. The efficiency or watts per candle-power is strikingly varied by the candle-power to which reference is made. In Table B are set down the efficiencies of each lamp of the five types, calculated on the basis of the candle-power values in Table A. A 3 5-watt lamp turns out to be

Digitized by Google

one which uses this much electric power per candle-power if this is reckoned at its highest value the mean horizontal. What a terrible inefficiency these lamps have if we calculate the watts per candle-power from the useful light or the light from their tips!

Lines *p* and *q* of Table B give this. Lamps 2 and 5 are the only ones whose efficiency reckoned in a rational way is at all reasonable. The lamps of Table B all were supposed to have the same average life and would not be very far different in maintenance of candle-power during life. If a lamp can be made which gives 16 c.p. out from the tip and burns at five watts per candle-power, we will have a lamp which is better than any now made. If its life is as good as the present 3·5-watt lamps, it would be a much better lamp than any we have now for all commercial usage. Keeping, however, to lamps now made, Table C. gives the relative cost of current per 16 c p. of useful light (light from the end) from each of the five different filament types now made. The computation is on the basis of 12 cents per kilowatt-hour for electrical energy, and the cost is per 500 hours of burning (the average life of a lamp).

TABLE C.

Type of filament.	Cost of current per 16 c p. of useful light and per 500 hours' service.
Single U-shaped	$9 43
Single curl	6 44
Long curl, anchored	7·62
Double	11 20
Double coil, tipless	5·32
Double coil (10-c.p. mean horizontal)	$4·10

Since we only use electric current in incandescent lamps for the light we get, and since it is the cost of the light which is the vital commercial problem, the table needs no comments to show which filament types are best—that is, which ones are most economical to use. I have put lowest in the table the cost of current per 16 c.p. of useful light from a standard 10-c.p. (mean horizontal) double-coil filament lamp. This lamp gives 8·2 c.p. out from the tip. It is worth noticing that a 10-c.p. lamp (so called), with this type of filament, gives as much candle-power out from the tip as any one of the other types which are rated at 16 c.p. Hence, such a lamp using only 35 watts gives as much useful light as any of the other four types, which require 56 watts.

INSTITUTION OF ELECTRICAL ENGINEERS.

Inaugural Address.

BY PROF. JOHN PERRY, M E, D SC., F R S, PRESIDENT.

I do not intend to make this in any sense a report of the progress of our Institution during the last or any number of years. I shall not, therefore, give any account of the exceedingly good work done by Colonel Crompton and the active service corps of our Electrical Engineer Volunteers in South Africa. I shall not describe how we fêted our American cousins in England and France, nor how they fêted us; nor what a wonderful success accompanied all that was attempted by us or by them or by M. Mascart and our French colleagues, although I cannot refrain from bearing my testimony to the great kindness of the Prince of Wales and the British Commission in so generously lending us the British Pavilion for our great reception and giving us the use of one of its rooms for our office all the time of our visit to Paris. My brother has tried to get me to introduce to your notice some novel ideas which have come to us during the last 10 years in our business of lighting the city of Galway from a fairly constant water power using accumulators with a gas plant stand-by. It has almost come to be a practical idea to produce carbide of calcium in wet seasons and utilise it through the gas-engine in dry seasons. I was also tempted to discuss the use of large gas-engine plant at central stations; and another of several subjects in which I have been recently engaged has been the magnetic effect produced by systems of electric traction. But I have resisted temptation, and have chosen a subject which seems to me much more important.

Your president's address is followed by no discussion. He is, therefore, privileged, but his very privileges cause him to address you with a greater sense of responsibility; he may say what he pleases, but he must be very sure that he has the best interests of the Institution at heart—the interests of the Institution as a whole, not the interests merely of a few members, and least of all ought he to think of his own interests. Nevertheless, your president speaks not as an omniscient judge, but rather as a very fallible, very prejudiced, one-sided man, who, because he has devoted himself to one part of the work of this Institution, is certain to be unfair in his comments upon other parts of the work. Your past presidents represent in this way all classes of members of this Institution. You have had scientific men, given some of them to calculation, and some to experiment, and some to both; men who have advanced the study of pure science. You have had practical telegraph men, civil and military, men cunning in land and deep-sea telegraphy and telephony; men cunning in railway signalling. You have had electrical chemists. You have had manufacturers and users of all kinds of electrical appliances. You have had men who devote themselves to the teaching of electrical engineers and who fully appreciate the fact that no good teacher ought to be out of practical touch with the profession. And nearly all of your past presidents have invented things which are now in practical use. As each of these men has given you at least one address written from his own peculiar point of view, his prejudices are not likely to have done any harm to members who read the other addresses. I know, therefore, that you are good-naturedly prepared to give me plenty of rope. I can predict the twinkle of amusement in the faces of some of my friends when they learn that I am about to take up a subject on which we have had many debates.

In this address I mean to put before you this simple question: Is electrical engineering to remain a profession or is to become a trade? Is this Institution to continue to be a society for the advancement of knowledge in the applications of scientific principles to electrical industries, or is it to become a mere trades union? Of course, at the present time the outside public are willing to regard membership of this Institution as a symbol of something more than the membership of a mere trades union. During the early growth of any trade, even such a trade as that of the plumber, it was really a profession. And a common trade may suddenly become a profession, if it suddenly begins to develop, as, for example, stonemasonry of a hundred years ago suddenly developed into civil engineering. Electrical engineering has been developed rapidly, so that in the past it has certainly been a profesion and not a trade. Again, we are an institution of engineers, and the general public are willing to class us with other engineering institutions—for example, the Institution of Civil Engineers. Now the title M.I C.E. is a professional distinction which represents in civil engineering what F.R.C.S. does in surgery, or M R C.P. in medicine. We owe a great deal to our association with, and recognition by, the Institution of Civil Engineers: our meetings are held in its rooms; many of our members are also its members; our proceedings are modelled on its proceedings.

Now this older institution, governed by the best thoughts of the best British engineers, has laid it down that its associate members, that important class from which the higher class is mainly fed, shall have passed certain specified examinations in pure and applied science. I am not now suggesting that we ought to adopt this science examination method of admitting any kind of members to our Institution. I do not believe in the wholesale adoption of methods of working from another society. I am asking you early in my address to remember that this greatest of all professional engineering institutions, governed by practical men full of common sense, knowing the wants of their profession well, insists upon a knowledge of science in its new members. If this recognition of science did not exist anywhere else in the whole world, I say that its recognition by such a thoroughly good professional society as that of the Civil Engineers ought to recommend it to all professional societies. In Germany an enormous stride has recently been made in the raising of

Digitized by Google

engineering degrees to rank with the highest university honours. There is hardly one engineer of eminence in Switzerland, France, or Germany who has not passed with honour through the classes of one of their great science universities.* In Great Britain within the last 15 years not only have great engineering schools been established in all the manufacturing towns, but even in Cambridge University there is one of the best schools of civil, mechanical, and electrical engineering of which I know anything.

Before we think of imitating the Institution of Civil Engineers, we ought to reflect on certain fundamental distinctions between that institution and our own which at first sight seem to make us less professional. There is a well-known unwritten rule of the Civil Engineers to which there are only a few exceptions, that no contracting railway or harbour engineer can acquire the title of M.I.C.E. I think myself that it is a pity to draw a hard-and-fast line between consulting engineers and contractors. No doubt it simplifies the labour of the council in its selection of candidates, but it gives rise to anomalies. A man who was once a civil engineer because he served a pupilage under his clever father, and who now is nominally at the head of his father's large practice, the real engineering work being done by many clever employés, this man may be a member. A contracting engineer who shows marvellous ability not only in rectifying the mistakes of the designer of a large bridge or tunnel or reservoir embankment, but shows the power of Lord Kitchener in directing the work of thousands of men so that no man need be idle, and the whole contract goes on like clockwork, and is finished well in the minimum of time, this man is ineligible. Now in our Institution it has been recognised from the very first that manufacturers and contractors and their employés may belong to the very highest ranks of their profession. Of course, I do not mean men who simply receive the profits of businesses, or even men who merely work to obtain orders for themselves. I mean men who are not merely formally, but in reality manufacturing or contracting engineers. I mean men who, in dealing with standardised things, design new methods for quick, good, cheap production of such things. I mean men who improve old forms of such things, possibly through their paid subordinates. I mean by a manufacturer fit to be a M.I.E.E. a man who might act as his own manager, and who perhaps, has a wider outlook than on mere managerial duties. So long as a contractor or manufacturer is really an engineer, we know that we add to our strength with the addition of every such member. But consider a contractor who only uses ordinary types of machines or electrical plant in well-known ways, surely he can hardly be said to be in the profession at all. Surely the one thing that differentiates us from mere tradesmen is that we do not follow mere rule-of-thumb methods; we think for ourselves, we weigh advantages and disadvantages. If every new installation required the same treatment as existing ones, the engineer would degenerate into a tradesman, and it seems to me that the electrical engineer ought to have a special fear of such degeneration. In railway and harbour and river and sanitary engineering, in every new job, there are new difficulties to be dealt with. An engineer who designs many undertakings and sees them carried out must be a thoughtful man. He cannot help keeping himself acquainted with engineering principles, and so he is a professional man. So an architect finds that each new job requires all his experience. Every case that comes before a real physician or surgeon requires a somewhat different treatment from any old case. Every case brought before a barrister requires the exercise of all his past experience. In every case a *profession* implies the necessity for the exercise of all one's past experience, because the work one has to do is never the same as any work one has ever done before; and when I say past experience, I really mean certain general principles which one has always in one's mind, principles derived from all that one has done, or seen, or read about.

Electrical engineering is in a curious position. It owes its being altogether to scientific men, to the laboratory and desk work of a long line of experimenters and philosophers. Even now the work going on in a laboratory to-day becomes the much larger work of the engineer to-morrow. When at length the laboratory experiment is utilised in engineering, we see that there is no other kind of engineering which so lends itself to mathematical treatment and exact measurement. Most of the phenomena dealt with by the electrical engineer lend themselves to exact mathematical calculation, and after calculations are made exact measurements may be made to test the accuracy of our theory. For a completed machine or any of its parts can be submitted to the most searching electrical and magnetic tests, since these tests, unlike those applied by the mechanical engineer, do not destroy the body tested. Contrast this with the calculations it is possible to make in other kinds of engineering. The pressure of earth against a revetement wall is possibly 200 or 300 per cent. greater, or 50 to 70 per cent. less, than what we imagine it to be in what some limited men call theory. We use factors of safety 5 or 10 or more on all kinds of iron structure calculations, because we are aware of our ignorance of a correct method of dealing with the problems. The civil engineer never has exactly the same problem as has already been solved. In tunnelling, earthwork, building, etc., in making railways and canals, he is supremely dependent on the natural conditions provided for him: the configuration of the surface of the ground, the geological formation, the structural materials available in the neighbourhood. The story of how the engineer has to study the endlessly different ways of interaction of water and sand and gravel is told by the troublesome bars at the mouths of rivers all over the world, by the difficulties of coast and river-bank protection, by the failure of sea-walls and piers. But why should I make a catalogue of the different kinds of work done by civil engineers? Every one of them needs the exercise of general scientific principles due to much experience.

Now of all such natural difficulties the consulting or contracting electrical engineer is greatly independent. Give him a source of power and tell him what is to be done; whether he is to light a town or a building, whether with arc or incandescent lights; whether he drives a stamp mill near a mine or a pump, or a machine tool, or a spinning frame, the electrical part of the work is carried out in much the same way. Natural conditions affect him mainly in the cost of transport of his materials and the cost of labour. He can make in an easy way the most careful calculations as to the best arrangement of his conductors and machines to give maximum economy, and except for this easy calculation his work is that of a mere tradesman. He is practically independent even of the weather. There are, indeed, some of us who grumble that this easy calculation is not made easier still, who prefer to make arithmetical guesses rather than exact calculation, because, perhaps, we like to see a little uncertainty introduced into the problem to make it more like a problem in civil engineering. I want members to see clearly that as time goes on, as our electrical engineering work gets more and more cut and dried, the man who loses the power to calculate, who loses his grip of the simple theory underlying our work, must sink more and more into the position of a mere tradesman who has no longer the right to call himself an engineer. An electrical engineer must have such a good mental grasp of the general scientific principles underlying his work that he is able to improve existing things and ways of using these things. It has become the custom to call this *theory*, and I suppose I must follow the custom. I should prefer to call it *science** or *knowledge* Do you remember

* I understand also that the great unions of manufacturers in *Germany* are about to make facilities for giving a year of real factory work to the polytechnic students, thus perfecting the German system. In Japan we found great success in requiring students to spend their summer in real shops, their winters at college. In England it may be that we shall prefer to let apprentices have shorter factory hours than workmen, their masters being responsible for instruction being given in theory.

* What Falstaff said of the word "occupy" we have to say of the word "science." It is used by many people out of its proper meaning and then condemned, so that one is getting afraid to use it. In Prof. Fitzgerald's splendid inaugural address to the Dublin Section of this Institution he says: "As has recently been pointed out to me by Dr. Trouton, it would be impossible to say the same contemptuous things of *knowledge* as are said of *science*. In Germany the word used, "Wissenschaft," is the one corresponding to our word 'knowledge,' and there nobody of any sense could say

Digitized by Google

Huxley's definition of science? "Science," he said, "is organised common sense," and this is really what I mean. Well, calling it *theory*, the man who is permeated by theory, whose theory is so much a part of his mental machinery that it is always ready for practical application to any problem, he is the real engineer. But you must not mistake me in this matter. Eighty per cent. of the men who pass examinations in mathematics, mechanics, and electricity have very little of this theory. Fifty per cent. of the writers of letters in the engineering journals in which mathematical expressions occur have almost nothing of this theory in their possession. It is unknown to foolish men. Books alone, lectures alone, experiments alone, workshop experience alone cannot teach this theory. The acumen of a Q.C. may actually prevent a man from acquiring it. A man may have much of this theory, although he may never have listened to lectures, although he may dislike the sight of a mathematical expression. I have known men who might be called illiterate to possess much theory. I have known many men who might be called good *electricians* who are almost wanting in the theory necessary for the electrical engineer. I am speaking only of theory. Of the other qualifications for an engineer I need not here speak; they are present to the minds of all of us. A man may have any amount of knowledge; he may know how to apply his knowledge, and yet he may not be able to apply the knowledge from a want of engineering *character*. The engineer must be a real man; he must possess individuality, the power to think for himself. He must not be like a sheep, knowing only enough to follow the bell-wether. Over and over again in the last 30 years have some of us given our students much the same sort of advice that Baden-Powell gives to scouts in that excellent little book of his. If any of you have not read that book you ought to buy it at once, and you will there find that if a man is to think for himself he must possess all kinds of knowledge, he must be constantly picking up new kinds of knowledge.

Nobody can limit the value of any kind of knowledge, but still one may say that certain things are probably more important than others. To gain what we call "theory" a good general education is most helpful—mathematical knowledge is very helpful; laboratory and workshop experience are extremely helpful. There is one qualification which the electrical engineer must have and without which all other qualifications are useless, and if a man has it no other qualification is supremely important, and this absolutely indispensable qualification is that a man shall love to think about and work with electrical things. He must like these not because of the money he can make through electrical contrivances, nor even, I think, because of the name he may make before the world—this would be mere liking or cupboard love, which has no lasting quality. So long as we have men in this country who have the true love for scientific work of which I speak, so long shall we have a real profession of electrical engineering, for such men are always scheming new contrivances and improving old ones and utilising the services of all helpful people, and especially of capitalists. When we have reached a state in which nobody schemes new things because the existing things are perfect there will no longer be a profession of electrical engineering. Of all ideas surely that of having reached *perfection* is most hateful: the idea of exact knowledge, that nothing is unknown, that there is no need for thought and therefore that to think for oneself is a sin. And so, although we are all agreed that much standardisation in our contrivances and methods is absolutely necessary for our competition with other nations, we must follow the Americans in this matter and take care that it does not destroy invention. Of course when things are really standardised, when we have our perfect Mauser rifle or dynamo or locomotive or traction engine or electrically-driven stamp mill, a Boer can buy or even manufacture them if he has money, and he can use them as well as, or possibly better than, we can. But he is not an engineer. He uses things after the engineer has done his work upon them. A stoker, a common engine-driver, the guard of a train, these are not engineers. You must have noticed that the American engineers, who surely deserve the character of being practical idealists above all other engineers, are the men who are most imbued with notions of standardisation which lead to cheapness of manufacture, and they are also the men most alive to the necessity for occasional extensive scrapping of types of machinery when they become even a little antiquated. Our chiefs—the men who run us all, our real men at this Institution—may be called practical idealists. They have imagination and judgment and individuality. They have the imagination and enthusiasm of inventors, and yet they are more than inventors, for they can estimate the worth of their own inventions and control their imaginations. They are ready to receive all new ideas, they welcome all new things, and yet they are not carried away. They are radicals, and yet they are conservatives. They have what Mrs. Beecher Stowe called *faculty*. A strong imagination well under control, surely it is the greatest of mental gifts. I look round me and wonder how many of us really have it, and how many of us are only dull music-hall loving men, who scorn novels and poetry, who live utilitarian, material lives, whose aim is merely to make money through electricity, who love it not for its own self, who cherish their "tuppeny-ha'penny-worth" of theory because it is sufficient for their immediate wants. Why, even the writers of leading articles in the daily papers can talk of the wonders of electricity, and what may yet come to pass, and yet we who make machines and use them, and switch the marvellous thing on and off, and take all sorts of liberties with it—we are like Calibans, oblivious of the wonders of the fairy isle—like soulless priests, making a living in the temple of Isis—like Aladdins, who rub our lamp only to get the necessaries of life.

Twenty years ago some of us were laughed at for our optimism, and yet everything that we declared then to be do-able has now actually been done by engineers, except the thing which was then and is now declared to be the supremely important thing—namely, the electric consumption of coal. We say now, as we said then, "The applied science of the future lies invisible and small in the operations of the men who work at pure chemistry and physics.' And think of the wonderfully rapid rate at which the laboratory discoveries have been made in the last 11 years, and how, as the years go on, they become more and more numerous, and yet many of us plod along with our work seeing no farther than our noses. A year is now more pregnant with discovery than a hundred years used to be, and yet the protective stolidity of our ancestors is upon us, and we think of the latest discovery as if it were really the very last that can be made. A thousand men are measuring and trying new things in laboratories all over the world. Some of them plodding and soulless; others of them with imagination and clearness of vision. Do you think that nothing is to come from all that work? And is not one of the most important functions of the engineer to do as Mr. Marconi has done—to convince capitalists ignorant of science that if the successful laboratory experiment is tried on the large scale it must also be successful? And are we going to leave all this pioneering work, with all its possibilities of great gain, albeit with possible loss, to foreign engineers, when in most cases the scientific discovery has been made in England? Are we so lacking in the hope and faith which are born of imagination and science? And must we in the future, as in the past, have to rely upon the influx of the clever foreigner like Sir William Siemens? Must we, Boer like, always depend upon our Uitlander population—Fleming and German, Hollander, Huguenot, and Hebrew—for the development of our natural resources?

Some of the best engineers I know are so exceptional that one must class them with geniuses; they have faculty and character, and so they have become engineers even under the most unfavourable circumstances. They have passed through ordinary schools and yet developed common-sense. They were pitchforked into practical work, and their liking for the work, as well as some curious kind of instinct, led them to pick up all sorts of knowledge which have become part of their mental machinery. They continue to pick up new kinds of knowledge when these become necessary for their pro-

that 'knowledge is all humbug,' as is here often said, and still oftener thought, of 'science.'"

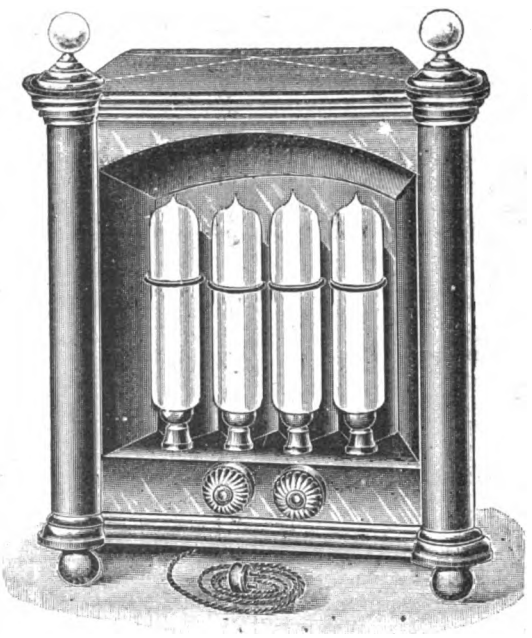
Digitized by Google

fessional work. Unfortunately these men do not realise how exceptional they are, and they advise boys to go direct from school into works. They forget that the other 99 per cent. of men treated in the same way as themselves can only become the hewers of wood and drawers of water to real engineers. Treated in this way, average boys are just like so many sheep: they learn just what seems absolutely necessary and no more; their acquaintance with the scientific principles underlying their trade is a hand-to-mouth knowledge which becomes useless when their trade undergoes development. In 1867 I was an apprentice, and when in the drawing office and pattern shop I remember well how I was chaffed for studying such a non-paying, non-practical subject as electricity. When I published my first electrical paper in 1874 before the Royal Society, and even for some years afterwards, the real students of electricity in England could be counted on the fingers of one's hands. Many of us remember the first Gramme magneto machine that came to this country, a scientific toy, in 1874. How many engineers dreamt that a great new branch of engineering had been started Even in 1878 engineers were, as a rule, quite ignorant of electricity, and since then every year, although newspaper writers have talked largely of the age of electricity, the men actually engaged in electrical industries have acted as if the greatest of changes were not perpetually going on in it. To be left behind, or to become camp followers, children of Gibeon, this is the usual fate of the men who scorn theory. In 1882-4 we used to have to pay men £200 or £300 a year because they had a slight knowledge of electrical matters. In 1884 6 these very men were not worth 20s. a week; they were weeded out of the profession, and their places were taken by men of better knowledge. Two or three years after, these better men were again found to have been weeded out, because men of still better knowledge were available. And so it has gone on ever since. Men learn just enough to get posts; they settle down in these posts and scorn theory. They actually forget what little theory they once did possess They know a great deal about existing machines, but presently they discover that improvements have been going on, and that they no longer have a right to say that they belong to the engineering profession. In every year one has told men, "You will be left behind. See A and B and C. I told them three years ago, when their names were in everybody's mouth, that they would be left behind like their predecessors, and they laughed. Now I tell you and you laugh, and you also will be left behind. Yes, I know that you get a good salary or large fees, and your head touches the sky. Nevertheless, because you neglect theory and the simple mathematics by means of which theory is made available in practical problems, you will have to take a back seat presently, for our profession is in its early youth and is growing rapidly." Remember that I do not now refer to the few exceptional heaven-born engineers who, in spite of bad training, do manage somehow to pick up the necessary knowledge. I speak of the average men, many of whom are now living in the same old fool's paradise. They know enough for present needs; they scorn the simple principles which underlie all our work; they scorn the easy mathematics by which these principles are most readily employed in practical problems; they will have their reward.

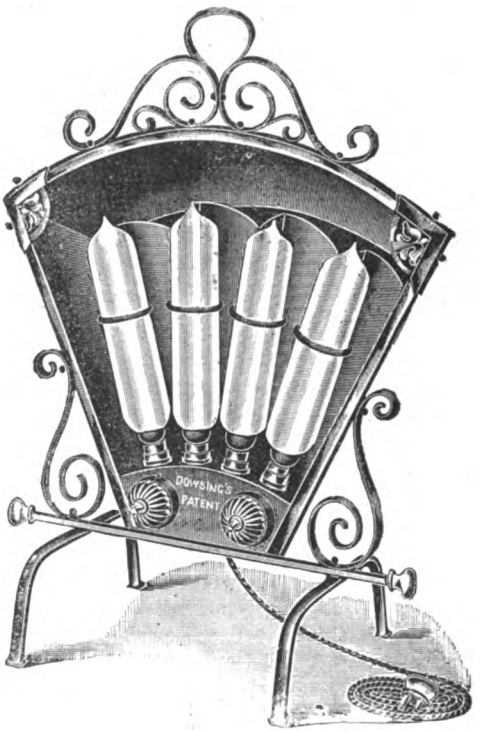
(To be continued.)

THE DOWSING ELECTRIC RADIATORS.

We have before now referred to the luminous electric radiators designed by Mr. H. J. Dowsing, but this week we were invited by that gentleman to inspect his new types, which, he rightly claims, are more serviceable than the older ones. In the illustrations herewith we show two of these new types, of which a description will be interesting. The so-called heat lamps employed are placed inside a radiator, the surfaces of which are, as a rule, highly polished, so that the heat may be reflected. As, however, the best of reflectors do absorb a certain amount of heat, Mr. Dowsing has arranged the forms of his reflectors so that there are vertical air passages behind them. Up these a draught is created on the well-known chimney principle, because the air becomes heated while in contact with the rear surfaces of the heat reflectors. The upper ends of these air tubes can be seen in the illustrations just above the ends of the heat lamps. The lower ends of these tubes are at the back of the radiator. The action then tends to circulate the air in the room, the cold air being taken up from the floor level. It then passes up through the radiator



and becomes heated. One result of this combination is that the radiators are more serviceable than those of the earlier type. With the ordinary type of radiator with heat lamps the consumption of electricity is one unit per hour. It must be remembered that central-station engineers are quite prepared to give special rates for electrical energy to be consumed for heating purposes; in fact, in many towns these radiators would be supplied at



1d. per unit, or, say, 8d. per day of eight hours. There are a number of rooms in every house in which it is difficult to know when fires will be required, and for these the electric radiators have special advantages. What, however, remains one of the greatest advantages of the Dowsing type of radiator is that they are exceedingly pleasant to look upon. They also give off heat immediately they are turned on, so that they are most serviceable in emergency.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

THE USE OF MATHEMATICS.

The President of the Institution of Electrical Engineers must not be classed with those prophets who prophesy smooth things. His address, delivered to the Institution last night, has many healthy criticisms both of the individual members of the electrical profession and also of the profession as a whole, in that it has allowed the electrical industry in this country to lag behind that in the States and on the Continent. With the fact that in certain respects Dr. Perry's charge is only too true we have to agree, and we have from time to time during the past few years commented on the indifference of electrical manufacturers in this country to improvements in types of machines and systems of supply which it was absolutely necessary they should adopt in order to retain control of the Colonial markets. It will, of course, be open to question as to whether Dr. Perry's solution of the chief cause of our backward position is a correct one. Personally, we believe that Dr. Perry is quite right in laying the great stress he does on the advantages of a working knowledge of the higher branches of pure mathematics, but there are many other causes at work, and we doubt if a knowledge of higher mathematics by certain members of the staff of a manufacturing firm will enable that firm to obtain the capital required to extend their works. The lack of capital easily obtainable for electrical ventures is a very serious drawback in England. Referring more, however, to the personal element, as Prof. Perry has done, our rising engineers must learn that pure mathematics applied without reason to engineering problems leads to disaster. We can point to numerous general solutions in mathematical form of particular electrical phenomena which are absolutely valueless save as a mathematical exercise, because they assume that certain constants exist and are obtainable when such is not the case. As a rule, however, a good knowledge of mathematics increases the aptitude of the student and the observation of physical facts, and the two in combination will be found a most valuable aid in professional life. We only wish that Dr. Perry's address was open for discussion.

THE MANCHESTER COUNCIL

The outcome of the enquiry undertaken by the special committee of the Manchester City Council into the charges brought by Mr. Norbury Williams against Mr. Alderman Lloyd Higginbottom has been the resignation of that latter gentleman from his position as alderman of the city, and consequently of the chairmanship of the Electricity Committee. Enquiry was made into the nine clauses in Mr. Williams's address which were directed solely against Mr. Higginbottom. Out of these eight were found to be without serious foundation, and the ninth was considered to be proved. This conclusion confirms what we stated in our leader last week, that the only objection which could be brought against Mr. Higginbottom was on the question of the supply of cranes. Evidence was obtained to the fact that out of six contracts for cranes Mr. Higgin-

Digitized by Google

bottom's firm had received, as sub-contractors, the major portion of the contract sums. If the engineers of the Gas and Electricity Committees had seen to the fulfilment of the common clause existing, we believe, in all engineering specifications on the question of sub-contractors, the so-called scandal in the present instance would have been avoided, as the name of the firm of Higginbottom and Mannock would then have had to come before the committees for approval. Still, Mr. Higginbottom has sinned against the law, and has suffered the extreme penalty of dissociation from the enterprise he has so ably controlled for many years. It has not, however, been proved against him that the contractors to whom his firm supplied goods for the Corporation did not in each case send in the lowest tender, or that they received any preferential treatment from the two committees or their engineers. It is, however, necessary that the Lord Mayor of Manchester shall be above suspicion, and we concur, therefore, in the course taken by the committee. Mr. Norbury Williams, as can be seen from the Manchester papers, is pleased with the success of his address, and in the pride of his success took it upon him to insult the Council as a whole. Thus in an address to the Manchester reporters immediately after the meeting on Monday, he had the impudence to wish the re-elected Lord Mayor "a happy and blameless year of office." We are also informed by the *Manchester Evening Chronicle* that "considerable further action against other members of the Council is most probable." The points arise out of the position of certain members of the Council on limited liability companies trading in that city. Such companies are not debarred by law from doing work for the Council, in spite of the fact that some shareholders may be either councillors or aldermen. The above paper states that, "unfortunately for the position of the members of the City Council, Mr. Norbury Williams is not satisfied with the law." When one considers the logical outcome of the position disclosed in our above-named contemporary, one is driven to the conclusion that the so-called reform party in Manchester will not be satisfied until all the members of the City Council are men absolutely without interests in undertakings in the city which may either directly or indirectly do business with the Corporation as contractors, or who may have to undertake negotiations with the Corporation. Such a restriction would prevent the best class of inhabitants from having any part in the government of their city. It is commonly stated that the man who successfully conducts his own business, making it a credit to the town he lives in, is the best qualified to assist in the ruling of that town. The Manchester reformers take the opposite view, which will only logically be fulfilled when the Manchester Council is elected from inhabitants of such far-away places as Lands End and John O'Groats.

New Canadian Cable.—It is reported that the Canadian Government intend having a short cable from Belleisle, Newfoundland, to Scotland, *vid* the North of Ireland. Canada's share of the cost would not be over £200,000, and the cost of cable messages would be reduced 6d.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

RATING OF INCANDESCENT LAMPS.

SIR,—You reproduce in your issue of the 19th ult. the first portion of a very interesting paper read before the Franklin Institute by Mr. Arthur J. Rowland. The paper deals with a matter to which my attention has for some time been directed, and which, so far as I am aware, has never, in view of its importance, been adequately studied (even admitting that it has been studied at all) by electrical engineers, either in this country or abroad.

The paper is entitled "Mistakes in the Rating of Incandescent Lamps," and it is, if I correctly appreciate it, designed to bring home to the public the erroneous conclusions which they come to in regard to the efficiency of electric incandescent lamps based on their arbitrarily marked candle-power.

Taking, by way of illustration, a 16-c.p. lamp, which is the one most commonly used, the author deals clearly and methodically with the questions of economy and efficiency, commencing with a statement as to what a lamp ought to be, then drawing attention to the importance of the light from the tipped end of the lamp, and describing the types of filament in use by the various manufacturers of lamps.

It seems incredible, after the lapse of so many years since the electric lamp became a commercial article, that so few attempts should have been made to utilise the rays of light emitted from the lamp in a plane at right angles to the filament, or, in other words, that makers of lamps should have practically ignored the fact that the length of the filament is a factor which determines the efficiency or candle-power of a lamp, and that any rating which disregards this is grossly erroneous. Lamps, however, have hitherto been rated according to their spherical candle-power, without regard to the fact that the light emitted from the end of the lamp is of prime importance, for the reason that the greatest number, probably 99 per cent. of the lamps in use, are suspended so that what may be termed the "side light" of the lamp is only partly utilised, and generally serves for the illumination of space, and is consequently often practically lost. In some installations, it is true, lamps are placed horizontally and reflectors are placed above them in order to obtain the benefit of this side light, but the arrangement is of such rare occurrence that it may be disregarded.

The diagrams appended to Mr. Rowland's paper and the description of the various forms of filaments which may be used with a view of giving the maximum efficiency at the tipped end of a lamp are most interesting, and shed a flood of light on the theories which the author enunciates. But as regards the filament, it seems clear that no form can be given to it which will render the light emitted at the end of the lamp equal, or nearly equal, to the side light. Hence, it behoves electrical engineers to endeavour to obtain some device which will intercept the side rays and divert them into the required direction *without diminution*, so as to obtain the maximum useful effect for a given consumption of current.

Mr. Rowland refers to the holophanes, which are no doubt useful devices, but which do not meet requirements, as they are expensive adjuncts, while their use is often precluded by reason of the cost of the installation, and they are apt to accumulate dirt. The use of a reflector, again, for the purpose of increasing the light below the lamp, is a crude attempt to solve the difficulty, for, apart from expense, a reflector, as the author remarks, cuts the light off absolutely in some directions, and so diverts it in others as to produce sharp shadows and brilliant lighting contrasts. Moreover, a reflector intensifies the light and thus increases the distress to the eyesight caused by the glaring filament, often necessitating the adoption of a ground glass or semi-opaque bulb to modify the light, so that while on the one hand some of the rays are refracted and diverted into the required direction, on the other hand the efficiency of the lamp is diminished. In other words, the account shows no balance to credit, the dividend earned being expended uselessly. The best type of what may be

Digitized by Google

termed a reflector lamp is that known as the improved glow lamp or Edison and Swan's "Queen" lamp, which is of flattened form and has a mirror-like backing, so that the light is powerfully projected downwardly when the lamp is hung from overhead.

What is required is a device which will both divert the side rays gradually and imperceptibly—*i.e.*, without any hard shadows or line of demarcation—and at same time screen the filament, that will be cheap, that will form a part and parcel of the lamp, and (which is of no less consequence) will be applicable to the lamps of all makers.

If the improved glow lamps were provided with a shade or screen which would conceal the filament while permitting the light to pass without undue diminution, it would be an excellent lamp, while the lamps of other makers would also be practically perfect if they were provided with a similar adjunct.

The nearest approach to what is needed seems to me to be the spiral globe, in which the bulb is enveloped by a spirally-coiled glass rod. This I have found a most excellent arrangement, as it does divert the side rays, and actually doubles the efficiency at the top or end of the lamp, as I have proved by the photometer. But the lamp is somewhat heavy and expensive, and does not suit all installations. But if someone could produce a screen partaking of the character of the spiral globe which could be applied to all kinds of lamps indifferently, he would earn the thanks of not only the public, but the makers of lamps also, as the serious objections raised to ordinary lamps would be got rid of, and consequently an increased sale of lamps would be the result.

I throw out the above suggestion, and trust that it will be carefully considered.—Yours, etc., H. A. HOBSON.

45, Lombard-street, E.C.

BURY ST. EDMUND'S.

SIR,—Referring to your notice of the Bury St. Edmund's plant, I have this morning received a sample from Mr. Roe, respecting which he writes that it was delivered by my heater detartariser at "top load." I have tested this sample, and find it to contain 2deg. of hardness. A sample of the main water which I tested in June last for the purpose of determining whether the use of soda would be necessary, showed the water to contain 19deg. of hardness, of which 3·5 consisted of sulphates and 15·5 of carbonates.—Yours, etc., WILLIAM BOBY.

London, Nov. 2, 1900.

ADVERTISEMENTS FOR TENDERS.

SIR,—In the interest of electrical agents, permit me to make some slight protest against the manner in which advertisements inviting tenders are too frequently worded. Often, for example, among the contracts advertised we find something of this kind: "The Corporation of —— invite tenders for the supply and erection of engines and dynamos. Specifications and forms of tender may be obtained on payment of a fee of three guineas, on application to," etc., no information being given about the type or size of engine and dynamo required.

An agent's profits are not so great that he can afford to risk many guineas on such indefinite grounds, with the probability that the specification will stipulate for one particular type of engine and some special features in the design of the dynamo which may prevent him tendering for those he represents, while an application to the consulting engineers for more definite information, before sending the prescribed fee, as often as not remains unanswered.

The objects in advertising for tenders are, presumably, to obtain the best possible machine for the required purposes and to encourage competition. These objects would, I think, be more readily attained were the advertisements to state clearly the required voltage and output of the dynamo, the type of engine, and whether the design of these is left open to the maker or is restricted by the terms of the specification. An agent or manufacturer could then tell at once if his machines were eligible for competition, and be saved the useless expense of applying for a copy of the specification, only to find himself unable to quote; while the advertisers would be more sure of obtaining tenders for those best suited to their requirements.—Yours, etc., W. H. MERRIMAN.

London, Nov. 7, 1900.

[N.B.—Mr. Merriman will find that in most cases such specification can, as is stated in the advertisements, be inspected at the offices of the consulting engineers. Such an inspection will enable manufacturers to determine, before expending the three guineas, whether or no they should be able to tender to the specification.—ED. *E. E.*]

PUBLIC OPENING OF THE BOROUGH ELECTRICITY WORKS, BURY ST. EDMUNDS.

The formal opening of the new electricity works at Bury St. Edmunds, fully described and illustrated in our issue of last week, took place on Tuesday, Nov. 6, when the Mayoress (Mrs. T. Shillitoe), in the presence of an interested assemblage of ladies and gentlemen, switched on the supply of current to the distributing mains. The MAYOR, in starting the first engine, alluded to the extreme pleasure which it gave him to be able to perform the ceremony during his year of office. He looked upon that day as a red-letter day in the history of Bury St. Edmunds, since it saw the completion of the long labours of the Electricity Committee which had been entailed in promoting the scheme. In this latter respect he could bear testimony as to the able manner in which Mr. Charles Oliver had discharged the arduous duties of chairman of the committee. The Mayor then called upon Mr. Oliver to start the second engine, which having been duly accomplished the Mayoress switched on the current, the supply thereupon being formally inaugurated. The subsequent inspection of the works revealed their very ship-shape order. A substantial job has been made of the battery-room, which was not quite fully equipped at the time of our previous visit to the works. The accumulators are arranged in three tiers with supports of cast iron. The connections from the battery are also very neatly disposed of.

After the inspection, a move was made to the Guildhall, where, in commemoration of the opening which had just taken place, a large number of guests were entertained by the Mayor and Mayoress to an excellent champagne luncheon.

In proposing the toast of "Prosperity to the Bury St. Edmund's Electricity Works," Mr. CHAS. OLIVER gave an outlined history of his association with the Electricity Committee as chairman, and commented upon the severe opposition with which the undertaking had had to contend with. But, notwithstanding the opposition, they were now in possession, he was pleased to say, of electricity works worthy of the town. He saw no reason why gas and electricity should be looked upon as directly antagonistic to each other; he felt sure there would be demands for both. Personally, he had come to the conclusion, after having put down for his own purposes the first private electric lighting plant in Bury St. Edmund's, that the new light was both economical and otherwise desirable as an artificial illuminant. For many years he had been a strong advocate of the electric light. With regard to their electricity works, there was only one fault concerning them which he had to find, and that was with the battery-room, which he considered should have been on the ground floor. He would couple with the toast the name of Mr. A. H. Roe, their resident electrical engineer, who was so ably promoting the interests of the undertaking.

Mr. ROE, in responding, expressed his regret at the opposition offered to the original scheme, but for which the town would have on that day been in the possession of an installation of public electric street-lighting in addition to the supply inaugurated. With regard to the popular idea that electrical energy was expensive as compared with gas, he would point out that electricity at 6d. per unit compared very favourably with gas at 4s. per 1,000 cubic feet. Electricity also facilitated further economy by the ease with which a lamp could

Digitized by Google

be switched off when not immediately required. He had great hopes of the future success of the undertaking.

The MAYOR, in very appreciative terms, then proposed the health of Mr. F. Hastings Medhurst, the consulting electrical engineer to the Corporation.

In returning thanks for the hearty manner in which the toast had been responded to, Mr. MEDHURST reviewed the difficulties which had been successfully encountered in connection with the scheme. With regard to the suggestion made by Mr. Oliver concerning the position of the battery-room at the works, he thought it strange that the criticism should not have been made when the designs were originally submitted for approval. In preparing those designs he had gone upon the same lines as he would have done had the moneys for their execution been coming from his own pocket. He had restricted expenditure so far as possible to immediate requirements, and this policy had been the ruling factor throughout. Provision had, however, been made to facilitate future extensions, and in this manner expenditure had been avoided for which there could have been no immediate return.

Alderman JOHN G. OLIVER proposed the health of the contractors. Messrs. F. J. ANSON and P. T. MOORE responded for Messrs. Fowler and Co., and Mr. POCKLINGTON for Messrs. Callender and Co.

The concluding toast—"Long life, health, and happiness to the Mayor and Mayoress"—was very heartily responded to, and this terminated a very enjoyable afternoon.

THE NEWCASTLE LOCAL CENTRE OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

Newcastle-on-Tyne is noted for the forwardness of its inhabitants, and in this respect the local centre of the Institution of Electrical Engineers is not behind. Thus, of all the local centres recently formed, it is the first to hold an annual dinner. This first annual dinner of the Newcastle centre was held on Wednesday last, when Mr. A. W. Heaviside, the president of the section, took the chair. Amongst those present were the Mayor of Newcastle (Sir Riley Lord); Prof. J. Perry, F.R.S., D.Sc., president of the Institution of Electrical Engineers; Mr. W. G. McMillan; the Rev. Principal Gurney; Mr. S. G. Weeks, president of the Institute of Mining Engineers; Mr. John H. Holmes, president of the Newcastle Association of Students of the Institute of Civil Engineers; Mr. J. M. Moncrieff, M.I.C.E., president-elect of the Newcastle Students C.E.; Mr. John Hay; Mr. C. L. Andrews; Dr. Stroud, and others.

After a well-served dinner, the usual loyal toasts were honoured, and Mr. J. F. C. SNELL then proposed "The Corporation and City of Newcastle-on-Tyne," to which the MAYOR responded.

The next toast was that of "The Learned Societies," and we may presume that the usual form of the toast was not adopted in order to cut away from under the feet of the proposer the usual jocular distinctions between the learned and scientific societies.

Prof. GURNEY, in reply lamented that this country had not taken the prominent lead it should have done in electrical engineering. He proceeded to review the remarkable developments of electrical engineering, and prophesied a most brilliant future for the profession. He even went so far as to say that the science was, "of course, still in its infancy."

It then fell to the lot of Prof. JOHN PERRY, F.R.S., D.Sc., to propose "The Newcastle Local Centre." He referred to the widespread influence which the Institution was exerting on the English-speaking world. Although London was the heart of their Institution, they knew that the heart was not really more important than the limbs, and he trusted that the particular limb of Newcastle would become of enormous importance, and vie with the centres in other large manufacturing districts. He proceeded to refer to the need of every exertion being made by the members to keep their industry well to the front.

The CHAIRMAN (Mr. A. W. Heaviside) replied on behalf of the section, pointing out that though they had a membership of 100, there was ample scope for a much larger support in the district which the section covered. He then referred to the development of the industry in the district.

A musical programme was interspersed with the various speeches.

OTTAWA AND ITS WATER POWER.

We have received from the Board of Trade of the city of Ottawa a copy of a most interesting book published by the Ottawa Free Press this year. In this volume illustrations are given of all the principal buildings in the town, and also of the health resorts near it. The various industries which are represented in the city and districts are also described, with numerous illustrations to exemplify the prominence to which these industries have been brought. The section of the volume most interesting to electrical engineers, however, is that which deals with the great water powers of the province. In connection with these a well-prepared map is given, to which we referred briefly a month ago. In this map the various rivers and lakes are shown, and the height and horse-power of the different falls are marked in red. In this way one can easily gather a good idea of the enormous water powers available, and also of their minimum and maximum values. For instance, with the Chats Falls, near Fitzroy Harbour, a 40ft. head is easily obtainable, while the horse-power would vary between 140,000 to 600,000. Another fall at Bryson has a 56ft. head, the horse-power available varying from 186,000 to 780,000. It would appear from this map that both of these falls are conveniently situated as regards water transit. Of the whole water power available, which comes out at about 1,000,000 h.p, over one-fifth is situated within eight miles of the city of Ottawa itself. These powers are in certain cases being utilised, and before long manufacturers in the province will have the full benefit of cheap electrical power. The advantage of this cannot be over-estimated, and when considered in connection with the natural advantages of the district, one cannot but predict a good future for the industries in question. What, however, is of more importance, is that these waterfalls offer such great opportunities for the establishment of new industries, such as the various electro-chemical manufactures in which electricity plays a prominent part. We think that every credit is due to the originator of the map in which so much information is given, and whom we understand to be Mr. Andrews Holland, a member of the council of the Ottawa Board of Trade. The illustrations of these various waterfalls in the volume are most interesting.

THE BIG SEARCHLIGHTS AT THE PARIS EXHIBITION.

We have received the following information about the searchlight on the tower of the German navigation section at the Paris Exhibition. This searchlight was quite a notable feature amongst the evening displays at the Exhibition, and it was available as an attraction when all the galleries of the Exhibition were closed. The searchlight in question was manufactured by the Schuckert Company, of Nuremberg, and is an outcome of the extensive experience which that firm has had in the manufacture of such apparatus It is now about 15 years since Mr. Sigmund Schuckert first succeeded in polishing glass mirrors into a true parabolic form. In devising the machine for this object he had the co-operation of Prof. Munker. The early machine for this purpose having proved successful, the firm commenced to turn out these mirrors in considerable quantities, and their great experience has enabled them to attain quite unprecedented accuracy even in large sizes. Thus the reflector of the large searchlight on the tower of the German navigation section has a diameter of 59in. The convex back of this glass mirror is covered by electrolytic means with pure silver. The arc lamp used in

Digitized by Google

connection with the same takes 150 amperes, and the crater of the arc is placed in the focus of the parabola. In the information before us an attempt is made to estimate the intensity of the beam of light produced by this searchlight, which is stated to be 180,000,000 c.p., but such comparison does not really hold, as one is comparing the light of a beam with that of a candle giving light in all directions. The dimensions of this searchlight are not extraordinary at the present time, as the same company exhibited a reflector of that size in Frankfort in 1891, and again in the International Exhibition at Chicago. It may be mentioned, however, that at Chicago the projector was placed at a considerable height, and that its beam was clearly visible at a distance of 170 miles. This projector was bought by the Government of the United States, and it is now in regular use in the Sandy Hook Lighthouse.

The Schuckert Company have, however, a much larger projector in the Paris Exhibition, in which a mirror no less than 79in. in diameter is used. In this case the electric lamp is constructed for a current of 200 amperes. The beam of light on the above-mentioned rating comes out at 300,000,000 c.p. The apparatus is heavy, as it weighs nearly five tons. In consequence of this, the friction had to be kept down in all the leading parts, and this was done by means of ball bearings. The carbons employed in the arc lamp are 49mm. and 35mm. diameter respectively. The mirror has a focal length of 34in. In addition to this, the searchlight has an arrangement for darkening purposes, constructed on the same principle as the Iris shutter used in photographic apparatus, and thus enables the light from the searchlight to be completely shut off. This arrangement is operated by means of a motor, and can be actuated from a distance. A hand-wheel also allows of the operation of this mechanism by hand. This searchlight is at present the largest in the world, and the accuracy of the polishing of the mirror is such that all the rays of a beam of light falling on the mirror in a direction parallel to its axis are united at the focus in a spherical space of not quite 2mm. diameter.

LIGHT RAILWAYS.

The enquiry into the Swansea light railway, which was adjourned from Swansea for counsel's speeches, was resumed at 54, Parliament-street, London, on Monday, before Mr. S. G. Fitzgerald. At the conclusion of the sitting, the Chairman said they would recommend the granting of the order of the scheme, subject to the introduction of clauses to carry into effect the undertaking given with respect to the reduction of speed and diminution of the other inconveniences mentioned when passing Mr. Harris's church, and subject also to the condition that if the Rhondda and Swansea Bay Railway Company pull down the Bridge Inn, so as to effect a public improvement, the Corporation shall pay the Rhondda Company £100.

It is announced that the Commissioners are prepared to sanction line No. 1 of the Rhondda Valley scheme, subject to a number of conditions which will be specified in writing to the promoters and to the various opponents.

The Santiago electric tramways, superseding horse traction, were inaugurated with much ceremony on Sept. 8. Over £600,000 will be required to complete the system.

It is stated that an application will shortly be made to the Commissioners on behalf of the London and South-Western Railway Company for permission to abandon part of the light railway they are authorised to construct from Grateley Station and Shrewton. If the application is granted the line will stop at Ratfin-road, Amesbury.

The Gloucestershire County Council will contribute £15,000 towards the Witney Burford and Andoversford light railway.

The Staines and Egham Tramways Company have decided to abandon their agreement with the Middlesex County Council to construct 31½ miles of light railways in Middlesex at a cost of £550,000.

The Middlesex County Council have finally approved an agreement between the North Metropolitan Tramway Company, the County Council, and the Metropolitan Tramways and Omnibus Company in relation to the working, purchase, etc., of the light railways under the county of Middlesex light railways joint order (northern lines), the important alteration being if the Council take over the Enfield and Waltham Cross lines it shall also purchase all the Council's lines in Middlesex and lease the whole of them. The Council also intend to apply for parliamentary powers.

THE FACTORS WHICH DETERMINE THE DESIGN OF MONOPHASE AND POLYPHASE GENERATORS.*

BY B A BEHREND.

(Continued from page 599)

In order to determine the dynamic characteristic from the static and short-circuit characteristics, which we assume to be known or predetermined (how this can be done will be shown in the third section of this article), we can proceed in the following manner:

If we assume that the armature reaction and armature leakage within the alternator have the same effect as an induction coil placed outside the machine, then the E M.F. which is to overcome the reactance of this coil must be in quadrature with the current, and as we take from the generator a wattless current, the E M.F. of self-induction is in an exactly opposite phase to the impressed E.M F. of the generator. Hence, in order to get a point of the dynamic characteristic, we should simply have to deduct the E M.F. consumed in the induction coil from the impressed E.M.F. of the alternator. If we take an ordinate of the static characteristic, and divide it by the short-circuit current belonging to the same excitation, we immediately get the reactance of the induction coil; or, as we assumed this reactance to be equal to the combined effect of armature reaction and armature leakage, this quotient gives us the apparent reactance of the armature. I say apparent reactance, as the real reactance may have a different value.

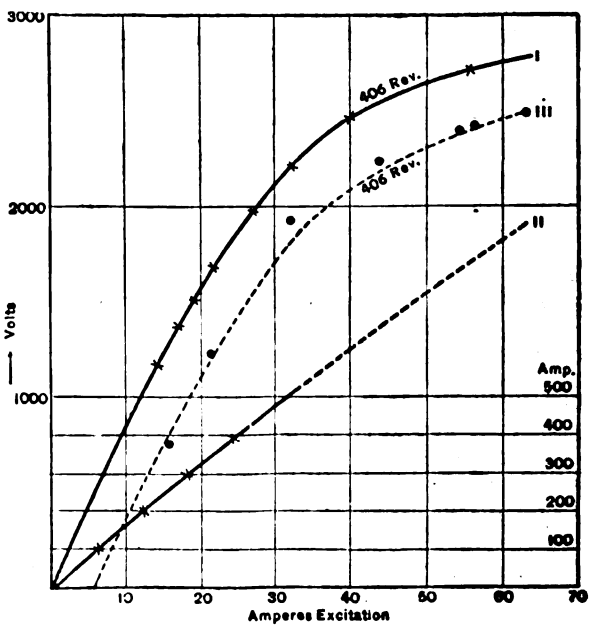

FIG 3.—Characteristics of Three-Phase Inductor Generator.

Mr. C. P. Steinmetz, in his admirable work "Alternating-Current Phenomena," first edition, p. 238, introduces for the combined effect of armature reaction and armature self-inductance (this term is here open to criticism, as the inductance is caused by the leakage lines of the armature current), the name synchronous reactance. The apparent reactance need not be equal to the synchronous reactance, though this is generally the case. We must bear in mind that the apparent reactance is a calculated value; hence these two quantities will be equal only if the method employed is correct. If we attempt to use the apparent reactance in the vector diagram for the determination of the power consumed by the circuit on which the generator works, we may be led into serious blunders. See for such an attempt Dr. Bohn-Eschenburg, *L'Industrie Electrique*, Aug 25, 1895. The E.M F. in the vector diagram is considerably greater than the real E M F. within the generator, on account of the armature reaction; besides, it is very doubtful whether we may rely on this method for power factors near unity. In this case the relative position of the armature with respect to the field is different from that at short-circuit, causing an increased self-inductance of the armature. If the iron in the armature

* From *Electrical World and Engineer* (New York).

Digitized by Google

between the slots is highly saturated, the distortion of the field caused by the armature currents will produce an additional drop just as in direct-current machines.

Let us now see whether this method yields results in conformity with fact and observation.

In Fig. 3 the Curve I. is the static characteristic of a 500-h.p. three-phase inductor generator for 2,000 volts between the lines. The speed is 406 revolutions per minute, the frequency 54. Curve II. represents the short-circuit characteristic. The generator was working on induction motors running light; the current was therefore practically in quadrature with the voltage at the terminals. The points marked represent an inductive load of 96 amperes. This current could not be taken out at voltages below 2,000 volts, as the magnetising current of the motors decreases with the lower voltage. It has therefore been necessary, in order to construct a curve for constant current, to make allowance for this difference. As the drop may, for low saturations, be set proportional to the current by which it is caused, the drop as represented by the points of Curve III. is obtained by multiplying the observed drop by the ratio 96 ÷ observed current. The broken line, Curve III., represents the drop calculated in the following manner:

For 62 amperes excitation the generator produces on open circuit 2,760 volts. The short-circuit current is 920 amperes. The apparent reactance of the generator for this excitation is given by the ratio 2,760 + 920 equal to 3·00. Hence the inductive drop for a current of 96 amperes is equal to 5 × 96 = 288 volts. This deducted from 2,760 volts gives 2,472 volts at the terminals.

TABLE I.

i.	I.	II.	*Et*	III.
62	2 760	920	2,470	2 472
56	2 710	840	2,410	2 400
54	2 690	815	2,390	2,373
44	2 550	680	2 230	2,190
32	2,220	510	1,900	1,802
31	1,650	340	1,230	1,184
15·5	1,270	255	747	792

Table I. is calculated in this manner. The first column contains the exciting current *i*. The second column, marked I., contains the volts on open circuit, interpolated from Curve I., in Fig. 3. The third column, marked II., contains the values of the short-circuit current, also interpolated from Fig. 3 The fourth column, marked *Et*, represents the volts at the terminals of the generator when working on the inductive load of 96 amperes. The fifth column, marked III., represents the calculated values of the terminal volts, as represented by Curve III. in Fig. 3. With the exception of the fifth series of observations, the agreement of calculation and experiment may fairly be called perfect. I am inclined to think that the disagreement in this one case is due to an inaccuracy in the measurement of either the voltage or the speed.

(To be continued.)

MANCHESTER ELECTRICITY COMMITTEE

The special committee appointed by the City Council of Manchester to enquire into the charges brought by Mr. S. Norbury Williams against Mr. Alderman Lloyd Higginbottom duly reported to the special meeting of the Council held on Monday last. As an outcome of this report, the meeting had also to receive a letter announcing the resignation of that gentleman.

The following is the full text of the report:

CITY OF MANCHESTER.

The special committee appointed by the City Council on Oct. 31, 1900, presents the following report, in pursuance of the instructions received by them—viz.:

"Resolved that this meeting at the close of its ordinary business be adjourned to Monday next, Nov. 5, for consideration of the allegations made by Mr. Norbury Williams against Alderman Higginbottom, and the statement of Alderman Higginbottom made this morning, and that in the meantime a special committee be appointed (for the purpose of considering the charges and reporting to such adjourned meeting of the Council), consisting of the Lord Mayor, Aldermen M'Dougall and Copeland, Councillors Edwin Holt, Shann, Plummer, and Vaudrey."

We met immediately after the close of the Council, and instructed the officials of the gas and electricity departments to be in attendance, with all books and documents, on the following morning. We also sent the following communications:

"Town Hall, Manchester, Oct. 31, 1900.

"Dear Sir,—I am desired by the special committee appointed by the City Council at their meeting held to-day to request your attendance at the Lord Mayor's office to-morrow (Thursday), at 10.30 o'clock a.m., in reference to the resolution copied on the other side.—I am, etc., THOMAS BRIGGS, Lord Mayor.

"S. Norbury Williams, Esq., Citizens' Auditor.

"P.S.—A similar communication has been sent to Alderman Higginbottom."

"Town Hall, Manchester, Oct. 31, 1900.

"Dear Alderman Lloyd Higginbottom,—I am desired by the special committee appointed by the City Council at their meeting held to-day to request your attendance at the Lord Mayor's office to-morrow (Thursday), at 10.30 o'clock a.m., in reference to the resolution copied on the other side.—I am, etc. THOMAS BRIGGS, Lord Mayor.

"Alderman Lloyd Higginbottom.

"P.S.—A similar communication has been sent to S. Norbury Williams, Esq."

We commenced our enquiry in the presence of Mr. S. Norbury Williams and Alderman Higginbottom on Thursday, Nov. 1, and continued it until after 6 p.m. on Friday, Nov. 2. Mr. Norbury Williams and Alderman Higginbottom attended throughout these proceedings, and addressed us from time to time. Several witnesses also attended before us, and have answered the questions put by the two above-named gentlemen and ourselves, and every opportunity has been afforded for the fullest explanation. At the commencement of the proceedings it was arranged, with the entire concurrence of Mr. Norbury Williams, that our enquiry should be confined to the items numbered 14 to 23 of his letter to the *City News*, and a print of those paragraphs, together with Alderman Higginbottom's speech in the Council on the 31st ult., is appended hereto.

Since the conclusion of the enquiry we have devoted several hours to the careful consideration of the evidence and statements placed before us by Mr. Norbury Williams and Alderman Higginbottom, and also of the information obtained by ourselves by means of documents called for or questions put by us during the enquiry. We propose to deal with the several items in Mr. Norbury Williams's letter *seriatim*.

Item 14. Having examined into the circumstances connected with item No. 14, referring to S. Z. de Ferranti, Limited, we find that this item has no bearing upon the subject of our enquiry.

Item 15. The British Insulated Wire Company, Limited.—We have enquired into this matter, and are satisfied that Alderman Higginbottom is not interested in this company.

Items 16, 17, 18, and 19.—After considerable investigation we find that neither the action of the British Electric Works Company, Limited, nor of Alderman Higginbottom as its chairman, has been such as to give rise to any substantial cause of complaint. One tender was sent in by this company without the knowledge of Alderman Higginbottom, who, on discovering it, instructed the chief engineer that it must not be considered, but it does not appear that this instruction was heard by the members of the committee present on the occasion.

Item 20. Purchase of scrap metal by the West Gorton Foundry Company, Limited.—As the company's tender was the highest, the Corporation suffered no loss by its acceptance, and we find that Alderman Higginbottom requested that it might be withdrawn, but the committee insisted on its being accepted. Alderman Higginbottom admitted the undesirability of this company sending in tenders to the Corporation.

Item 21. The scale of charges for supply of electric power, to which exception is taken in this paragraph, is purely a question of the policy of the Electricity Committee itself. This scale was fixed by the Electricity Committee on the recommendation of the chief engineer, and is very similar to that adopted in some other large towns. The imputation that Alderman Higginbottom was instrumental in reducing the price of supply for motors in order to promote his own business interests we find to be absolutely without foundation.

Item 22. Cranes at Corporation Gasworks.—We have carefully considered this matter, and have referred to the minutes and documents in the gas department. We find that, although Messrs. Frank Pearn and Co., Limited, took the contracts for doing the work, they sublet in some cases the whole and in other cases portions thereof to Messrs. Higginbottom and Mannock.

Item 23. Cranes at Electricity Works.—We find that Messrs. Higginbottom and Mannock have acted and are acting as subcontractors in reference to the manufacture and fixing of cranes in connection with the electricity works of the Corporation.

Digitized by Google

We find that the transactions have been as follows (the amounts of the sub-contracts given below were stated by Alderman Higginbottom in his evidence before us):

(*a*) That on March 14, 1892, a tender was accepted from Messrs. H. and J. Ellis amounting to £446 for work for the electricity department of the Corporation, and that Messrs. Higginbottom and Mannock were sub-contractors in this contract.

(*b*) That on Sept. 23, 1892, a tender was accepted from Messrs. Mather and Platt, Limited, amounting to £230 for work for the electricity department of the Corporation, and that Messrs. Higginbottom and Mannock were sub-contractors in this contract to the amount of £150.

(*c*) That on Jan. 26, 1898, a tender was accepted from Messrs. Thomas Parker, Limited, amounting to £528 for work for the electricity department of the Corporation, and that Messrs. Higginbottom and Mannock were sub-contractors in this contract to the amount of £307.

(*d*) That on June 7, 1898, a tender was accepted from Messrs. Thomas Parker, Limited, amounting to £1,545 for work for the electricity department of the Corporation, and that Messrs. Higginbottom and Mannock were sub-contractors in this contract to the amount of £950.

(*e*) That on Feb. 14, 1900, a tender was accepted from Messrs. P. R. Jackson and Co., Limited, amounting to £1,808 for work for the electricity department of the Corporation, and that Messrs. Higginbottom and Mannock are sub-contractors in this contract to the amount of £1,440. [This contract is still in course of execution.]

(*f*) That on May 12, 1900, a tender was accepted from Messrs. the British Schuckert Electric Company, Limited, amounting to £1,750, for work for the electricity department of the Corporation, and that Messrs. Higginbottom and Mannock are sub-contractors in this contract to the amount of £1,382. [This contract is still in course of execution.]

In conclusion, we are of opinion that the action of Alderman Higginbottom with respect to these sub-contracts, as well as to those referred to in item No. 22 of this report, has been altogether improper, and such as the committee cannot justify, having regard to his position upon the Electricity Committee and the Gas Committee.

THOMAS BRIGGS,	W. H. VAUDREY.
Lord Mayor, Chairman.	HENRY PLUMMER.
ALEX. M'DOUGALL.	EDWYN HOLT.
A. G. COPELAND.	T. THORNHILL SHANN.

Town Hall, Manchester, Nov. 3, 1900.

After the meeting, Mr. Norbury Williams made a statement to the Press to the effect that he was not to blame as to the time selected by him to publish his address. This he had done as soon as he had acquired the information in question, and he professed that six weeks ago he did not know of the irregularities he afterwards complained of. Mr. Williams proceeded to hint at further revelations being likely as regards the Electricity Committee, and concluded his statement by wishing the re-elected Mayor a happy and blameless year of office.

LEGAL INTELLIGENCE.

WOLVERHAMPTON CORPORATION v. BRITISH ELECTRIC TRACTION COMPANY.

In the Chancery Division, before Mr. Justice Joyce, Mr. Thompson on Nov. 2 made an application for the defendant company. He said the action was one for the specific performance of an agreement for the sale of certain tramways, and the substantial question in dispute was whether under certain Acts and provisional orders the defendant company were entitled to have running powers over certain of the Wolverhampton tramways. The defendants had retained Mr. Cripps, Q.C., but yesterday they heard that he had decided to go abroad, and would be unable to take up any case for three weeks. He now asked that the case should stand over for that period.

Mr. Hughes, Q.C., for the other side, opposed. He said the question affected the whole matter of the Wolverhampton trams, and the Corporation were very anxious to have it settled.

Finally, it was decided that the case should be taken on Thursday next, subject to any part-heard case.

CLAIM BY THE NATIONAL ELECTRIC WIRING COMPANY.

In the Westminster County Court, on Friday, before his Honour Judge Lumley Smith, Q.C., the case of the National Electric Wiring Company *v.* Jones was tried. It was an action by the plaintiffs, who carry on business at Charing Cross-road, to recover the sum of £61 in respect of electric wiring and fittings supplied to the order of the defendant, who carries on the business of an hotel keeper in the Strand. The defendant did not dispute having given the order for the wiring and fittings, but set up a counter-claim in the way of damages on the ground that the installation was badly done.

Mr. Jenkinson was called, and said that at the time the work was carried out he was general manager of the plaintiff company, and it was within his knowledge that everything was done to make the work complete. It was passed by the inspector of the company who supplied the light, and that was a guarantee that it was efficiently done.

After hearing the evidence of the defendant and his witnesses as to certain defects in the work, his Honour gave judgment for the plaintiff company for the amount claimed (£61), and judgment for the defendant on the counter claim.

BIRD v. THE DUBLIN UNITED TRAMWAY COMPANY.

On Monday at the City Sessions, before the Recorder, the case of John Bird, of 32½, Dawson-street against the Dublin United Tramways Company to recover damages for personal injuries received by the complainant on Sept. 24 by being knocked down in Dawson-street by an electric tram, which was opened on Saturday, was resumed.

Captain Greeley, examined by Mr. Brady, solicitor for the plaintiff, stated that, in his opinion, the tram conductor was in fault.

Mr. Kelly, examined, stated the plaintiff was hunting a collie dog, and suddenly turned on to the tramline. The tram conductor could not have pulled up in time to save him.

The Plaintiff said he was not getting justice in that court as a working man. There were witnesses for him that were not called.

Mr. Brady said they could not be found.

The Recorder said that if the plaintiff thought he was not getting justice there he would give him an opportunity of having the case heard elsewhere, and would dismiss it on the merits. He had three witnesses to one, and adjourned the case in order to give the plaintiff an opportunity of examining more witnesses. If people went hunting collie dogs in the street they must be careful. He dismissed the case on the merits, with costs.

FORTHCOMING EVENTS.

FRIDAY, NOV. 9.

Faradian Club.—At 8 p.m., at St. James's Restaurant, club smoking concert.

Physical Society.—At 5 p.m., ordinary meeting. Papers on "Electromotive Force and Osmotic Pressure," by Dr. R. A. Lehfeldt; "On Astigmatic Lenses," by Mr. R. J. Sowter; "On a Phase-turning Apparatus for use with Electrostatic Voltmeters," "On a Method of Measuring Power in Alternate-Current Circuits," and a "Note on obtaining Alternating Currents and Voltages in the same Phase for Fictitious Loads," by Mr. A. Campbell, B.A; and "On the Refraction of Sound by Wind," by Dr. E. H. Barton.

SATURDAY, NOV. 10.

Glasgow and West of Scotland Technical College Scientific Society.—At 7.30 p.m., at Glasgow, adjourned discussion of a paper on "Slow-Speed Engine Design," by Mr. A. M. Downie.

MONDAY, NOV. 12.

Institution of Electrical Engineers (Newcastle Section).—Opening meeting.

TUESDAY, NOV. 13.

Institution of Civil Engineers.—At 8 p.m., ordinary meeting. Paper on "The Metropolitan Terminus of the Great Central Railway," by Messrs. G. A. Hobson and E. Wragge.

Institution of Electrical Engineers (Manchester Section).—Opening meeting.

WEDNESDAY, NOV. 14.

Institution of Electrical Engineers (Glasgow Section).—At 8 p.m., opening meeting. Paper on "Electrical Supply," by Mr. W. A. Chamen.

Institution of Electrical Engineers.—At 7.30 p.m., students' meeting. Paper on "Overhead Line Material," by Mr. A. J. Le Hurst.

THURSDAY, NOV. 15.

Chemical Society.—At 8 p.m., ordinary meeting.

FRIDAY, NOV. 16.

Institution of Mechanical Engineers.—At 8 p.m., ordinary general meeting. Paper on "Capacity of Railway Wagons as affecting Cost of Transport," by Mr. J. D. Twinberrow.

Electro-Harmonic Society.—At 8 p.m., at St. James's Hall Restaurant, evening concert (ladies' night), Major Crompton presiding.

North-East Coast Institution of Engineers and Shipbuilders.—At Sunderland, ordinary meeting.

SATURDAY, NOV. 17.

Glasgow and West of Scotland Technical College Scientific Society.—At 7.30 p.m., ordinary meeting. Paper on "Some Notes on the Organisation of a Workshop," by Mr. H. D. Jackson.

North-East Coast Institution of Engineers and Shipbuilders.—At Newcastle, graduates' meeting. Paper on "Comparison between British and American Locomotive Practice," by Mr. H. J. Potts.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

323. In alternating-current supplies with networks of concentric cables, in switching on and off there is a danger of breakdown in the insulation between the outer main and the lead covering. What is the best way to prevent this defect?—K.

324. Compare the cost of lighting by direct and alternating current arc lamps respectively.—K.

ANSWERS.

Question No. 317.—Describe and sketch the cheapest form of main and distribution switchboard suitable for a small private station of two 65-kw. steam dynamos at 100 volts; first, with the necessary switching arrangements for accumulator charge and discharging; and, second, without same.

Best Answer to No. 317 *(awarded* 10*s.)*.—Two 65-kw. sets do not form a very small private station, and with plant of this capacity it would be foolish to go in for some cheap pattern of switchboard, but it should be of substantial design, and the writer suggests the one according to sketch to be used with a storage battery. The current from the dynamos is controlled by two main switches capable of carrying 600 amperes without heating, in connection with which is the main fuse; two dynamo ammeters reading to 600 amperes; bars arranged with plugs so that any combination may be obtained in working (two of these bars on each pole could be placed at the back of the board, which would diminish the cost, as they could be finished rough); six-way charge and discharge battery switch, the contacts of which consist of two separate bars, which are connected together through a resistance coil, which prevents the short-circuiting of a cell when passing from one contact to another; accomplishing the regulation without breaking the circuit, these switches to carry about 200 amperes; capacity of cells taken at 200 amperes for five hours. A magnetic cut-in and cut-out is very useful in charging accumulators, as it automatically cuts in or out if from any cause the E.M.F. of the dynamo falls below the required standard. A combined charge and discharge ammeter reading to 300 amperes, which also records at a glance whether battery is charging or discharging. A voltmeter reading to 150 volts with a five-way double-pole voltmeter switch, which is connected to different parts of the board as required (connections to voltmeter switch are not shown to avoid complication).

The distribution part of the board has been allowed for 10 100-ampere circuits, which is provided on one side with a two-way throw-over switch so constructed that the connection is made on one side before the other side is broken (see elevation at A) By this means the current on any circuit can be measured independently by means of ammeter 300 amperes. This switch will also act as a duplex fuse in case of emergency. On the other pole the circuits are taken through lever bar switch cut-outs (see elevation at B).

The price of this board with moulded teak frame on enamelled slate would be about £110; this could be reduced to £95 by having a simpler charge and discharge switch, and instruments with 7in. dials; by doing away with the accumulator portion the cost would be about £86.—W. A. J.

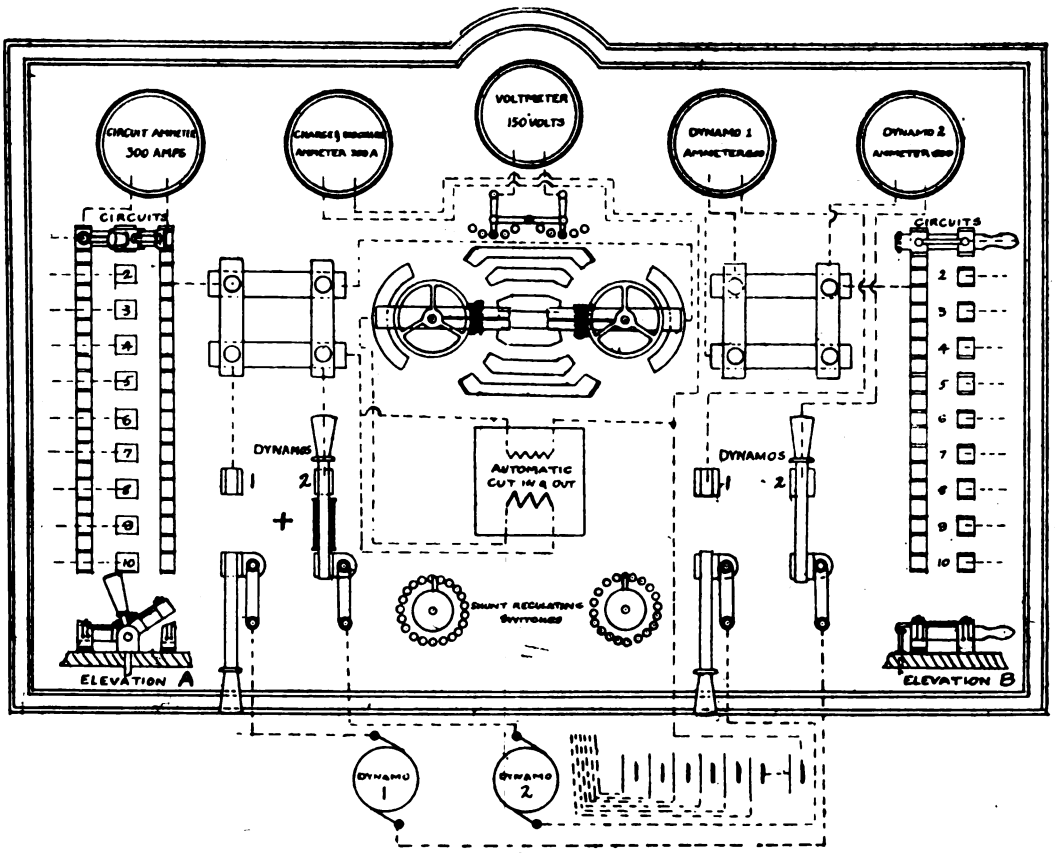

Diagram of Connections.—W. A. J.

Answer to No. 317 (*awarded* 5*s.*).—The question before us is one of interest, especially to the installation contractor, for there is at present a demand for "a good job at a low price." Having to comply with this request, contractors are anxious to obtain inexpensive material, which at the same time is of the best and thoroughly reliable; also to do away with those accessories which are not essential, and yet to have the job in every sense complete.

The particular case before us—viz., switchboards—is one in which great care should be taken, as unsuitable switching arrangements often lead to trouble, and prevents the plant from being run in the most economical manner; at the same time the board should not be designed with instruments, switches, fuses, etc., that are unnecessary.

Digitized by Google

The accompanying diagrammatic sketches show two boards, the connections of which will explain themselves. The writer has assumed the two dynamos are to work separately or in parallel, also that there are six main distributing circuits, as would be the case in a building with six floors, these circuits being taken to smaller distributing boards on their respective floors. Each machine gives 65 kw. at 100 volts = 65,000 watts at 100 volts = 650 amperes at 100 volts.

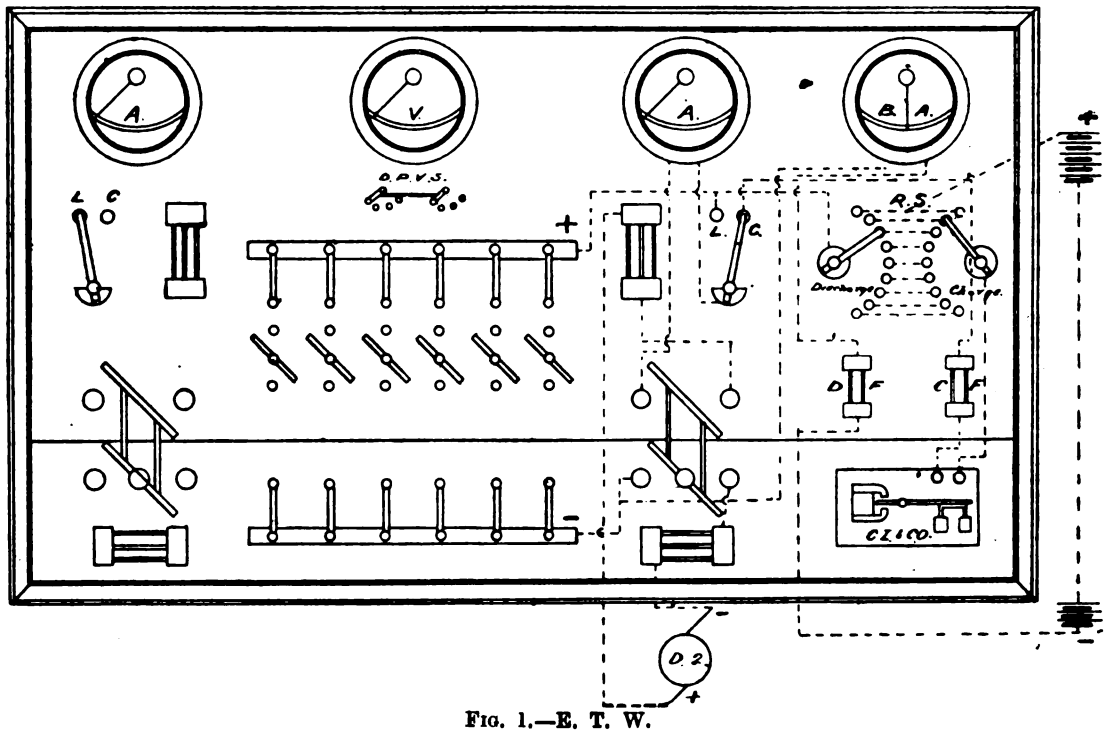

FIG. 1.—E. T. W.

Taking, firstly, the second board, the one without the accumulator charging devices, it will be seen that it contains the following instruments, switches, etc.: two ammeters reading up to, say, 800 amperes; one voltmeter reading up to, say, 150 volts; two double-pole, double-break main switches to carry 650 amperes; four main fuses to carry, say, 800 amperes; six branch double-break switches to carry, say, 150 amperes; 12 branch fuses to blow off at, say, 200 amperes; one three-way double-pole voltmeter switch. The board is made up of two enamelled slates, and fixed in a hardwood frame. The working of this board will be obvious, therefore further comment is needless.

The first diagram shows the arrangement for charging and discharging accumulators. In addition to the instruments, etc., enumerated for the second board, there are the following: two two-way main divisional switches, marked L C; one battery ammeter to read the charging or discharging current on either side of the zero; one battery-regulating switch for charging and discharging; two fuses, D F and C F; one automatic cut-in and cut-out switch; one four-way double-pole voltmeter switch in place of three-way ditto before mentioned. An inspection of the diagram and connections will show the method of working the board to be: for charging divisional switch, L C is turned on to C, contact. The current passes from here to fuse C F, which should be regulated to blow at 50 per cent. above the maximum charging current. The current next passes through the automatic cut-in and cut-out. The function of this instrument is, when the dynamo voltage is slightly in excess of the battery voltage, to cut in the battery-charging switch. If from any cause the battery voltage rises above that of the dynamo, the charging switch is cut out, thus disconnecting one side of the dynamo from the battery and preventing the possibility of reversing the machine. *For running direct* on to the main circuits, the divisional switch is turned over on to contact marked L. When in this position the battery is in parallel with the dynamo through the discharge regulating switch. In this manner any fluctuation of voltage is taken up by the battery, thus insuring steadiness to the lights. *For discharging* from the battery alone, it will be seen that the current passes from the battery through the discharge regulating switch on to the positive 'bus bar, returning from the negative 'bus bar through the battery ammeter and the fuse, D F, to the negative side of the battery. The function of the fuse, D F, is to prevent too great a current being taken from the battery, and ought to be rated at 50 per cent. above the battery maximum discharge current. It will further be seen that one dynamo can be run direct on to the load while the other is charging; also that one machine can be charging and supplying current for a load simultaneously.

For the sake of clearness a number of the connections have been omitted, but this should cause no difficulty. By using a voltmeter switch, one voltmeter is used to read the voltages on the respective dynamos and the battery. It will be noticed that, though the dynamos are intended to work in parallel, no minimum cut-outs have been provided.

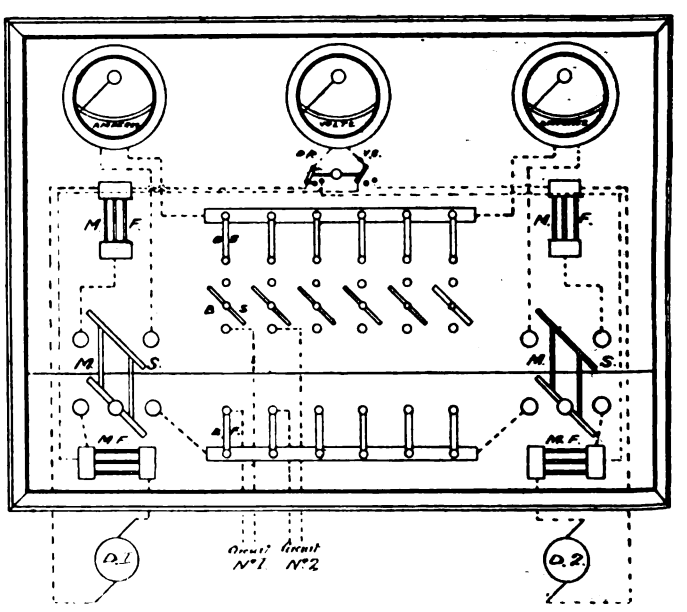

FIG. 2.—E. T. W.

Further, that there are no shunt-regulating switches for the dynamos. The writer thinks these to be hardly necessary; there are many similar private stations working efficiently without them.

The price of these boards may be greatly reduced by (1) working in with the makers' standard designs as far as possible; (2) having no bright metal work except the

Digitized by Google

rubbing contacts; (3) by working the metal parts at 25 per cent. greater density than the standard. The standard densities for the highest-grade boards are: copper, 1,000 amperes per square inch; gunmetal, 640 amperes per square inch; brass, 300 amperes per square inch. This increasing the density is a usual method adopted by some of the best makers for their second-grade boards.—E. T. W.

Answer to No. 317 *(awarded* 5*s.).*—The conditions laid down in the question are somewhat exacting and, indeed, impossible were they to be taken literally. One cannot have both the best and the cheapest of everything, although your client or customer almost invariably asks for it. What they get is a fair compromise between the two, and the extent to which one has to give way to the other almost entirely depends on how much money your customer has to spend and how far he will go in sacrificing convenience of running the plant to a low first cost.

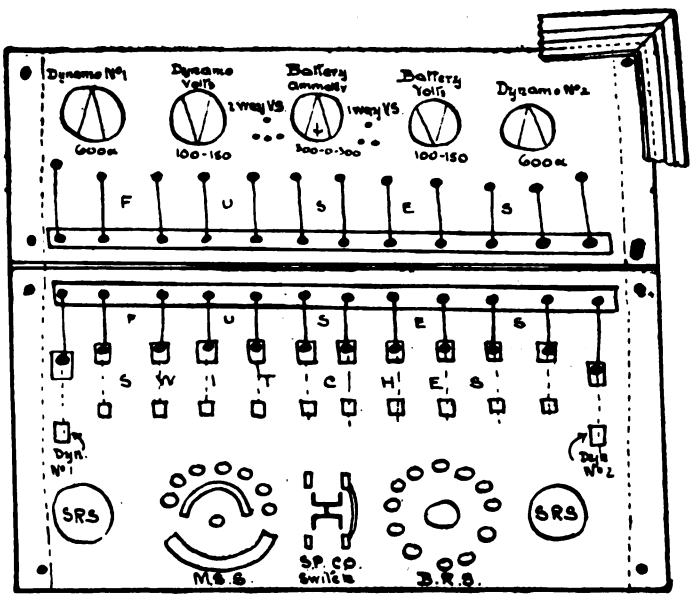

FIG. 1.

The switchboard shown in Fig. 1, the connections of which are given in Fig. 2, is of a type which obtains fairly often in installations of this kind. The arrangements are not elaborate, but will enable the plant to perform the work quite satisfactorily. The two generators are each provided with an ammeter, a single-pole switch, and double-pole fuse connected on to the + and − 'bus bars. The shunt-regulating switches, S R S, are shown on the lower panel and should each have about 15 stops. In the diagram (Fig. 2) it will be seen that the shunts are excited

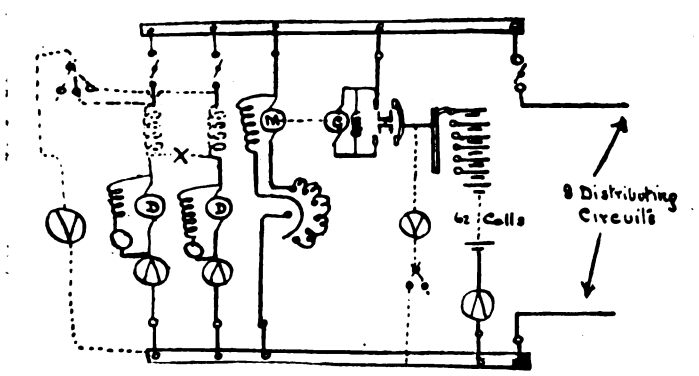

FIG. 2.

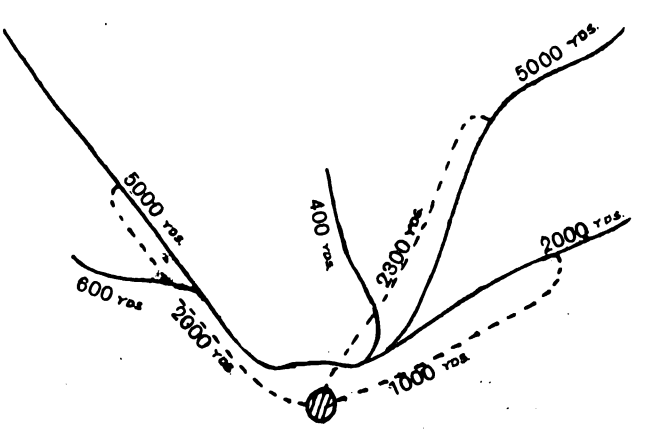
off the generator terminals instead of the 'bus bars, thus dispensing with shunt-breaking switches. The board is arranged for shunt-wound dynamos, but for compound-wound dynamos an additional switch has to be provided, shown at X in the diagram. This puts the series windings in parallel.

The writer considers that in connection with such large generators (for a private plant) it is the better plan to use a "booster" for charging purposes instead of the usual charge and discharge switch. The latter arrangement would involve sending very large currents through the regulating cells when maintaining a large load and charging the battery at the same time; also the first arrangement admits of great flexibility of manipulation, although more costly. We have a 15-way battery-regulating switch, B R S, the centre contact of which is joined to a two-way or change-over switch, which includes the generator of the booster set in the battery circuit or not according as the position of the change-over switch is up or down. This generator is driven by a motor connected across the 'bus bars, and its speed is varied, and consequently the generator volts, by means of the motor starting and regulating switch, M S S. When the battery is being charged all the regulating cells are cut in, and the booster set started, the voltage of which can be varied in order to keep the charging current at its proper value. In practice the booster in this case should be capable of generating about 40 volts at the charging current. There are shown eight 150-200-ampere single-pole switches and double-pole fuses attached to the 'bus bars for distributing purposes. The number and size of these, however, will be determined by the actual requirements of the plant. The remaining apparatus on the board are: an ammeter for the battery circuit; a dynamo voltmeter, with a two-way and off single-pole switch and a battery voltmeter; and one-way and off single-pole switch. The instruments may be of the ordinary type, with soft-iron attraction, of which there are plenty of makes at moderate prices. The fuses should be composed of tin strip secured to the 'bus bar by a stem and a nut or terminal head. On the lower panel these fuse terminals are attached to the top contact of a single-pole switch, which may be of the knife pattern. The change-over switch is shown as a chopper-type switch for the sake of clearness. The battery-regulating switch may be of the circular pattern with sector-shaped contacts, and the arm provided with a non-short-circuiting device. The contacts of the motor-starting switch may be similar to the above-mentioned, and provided with a shunt ring, which can be arranged to break a little after the armature circuit, and fitted with a non-inductive resistance. Cable connections should be made at the back by means of cable sockets attached to copper or gunmetal stems coming through the board from the various switches, etc.

The apparatus may be mounted on enamelled slate or marble, metal work of opposite polarity being on separate slabs as shown. The panels are supported on angle-iron uprights by means of bolts at the corners, the holes being bushed with ebonite for insulating purposes. The whole may be surmounted by a neat teak moulding to give the board a good appearance if desired. The board can be supported away from the wall by means of tiebars grouted into the wall. The angle-iron uprights may terminate in cast-iron feet fixed in concrete floor, and the board placed at such a height that the switches can be operated easily and the instrument readings taken from any part of the room. For an installation without battery the arrangement of switchboard would be the same with the exception that the change-over switch, motor-starting switch, and the battery-regulating switch would be left out.—E. J. EVANS.

Question No. 318.—In a traction scheme, as per appended sketch, would it not be advisable to feed the trolley wires

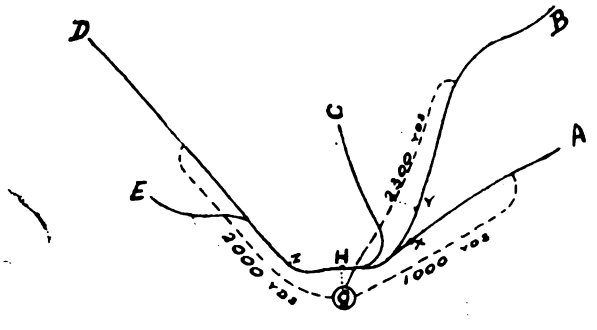


at the station in addition to the feeders, or would it be best to transmit all the energy through the feeders and not tap on to trolley wires at station?

Digitized by Google

Best Answer to No. 318 (*awarded* 10*s.*).—From the sketch I should gather that the whole system of trolley wires are electrically connected together independently of the feeders, and although such a system has the disadvantage that no one feeder circuit breaker will deaden a section of the line on which a serious short has occurred, leaving the remainder of the system in working order, we will deal with the question as it stands.

Referring to figure, to take a tapping from the trolley wire at a point adjacent to the station, G, may be done in two ways. One would be to run a short cable from the + station 'bus bar direct to H. This would necessitate another circuit breaker and feeder switch on the switchboard, and also arrangements (such as a street switch pillar) for making connection with the trolley wire. The other way would be tap from either of the feeders leading to A and B, and so make use of their circuit breakers and switching arrangements, but in this case also we should require a switch box to be built in the street. If all the feeders are taken from a common 'bus bar, the point H will be, owing to its relative shorter distance from G, of a higher voltage than either of the other feeding points, and as all the trolley wires are connected, feeding will take place from this point in each direction up to such points, that the drop in voltage from G, *viâ* H, to these points is equal to the drop *viâ* the original feeder in each section. These points will be continually shifting, their exact locality depending upon spacing of the load on each line at a particular instant, and upon the resistance of the feeders; but for the purposes of the question we may take it that, as an average, the current required for the whole of C, together with about 1,200 yards of B and 600 yards of A, will be passing through H to the right and, perhaps, the whole of E + 1,200 yards of D to the left. From this it will be seen that if method *b* has been adopted in making the tapping, the circuit breaker on the feeder from which the tapping has been taken will have to be of largely increased capacity; and if this is installed, the current flowing between the tapping and G along the feeder will be enormously in excess of its original value, and if the size of the feeder were just sufficient in the first instance, it will be very largely and dangerously overloaded at its station end as a consequence of the new feeding point. This practically disposes of *b*, and leaves *a* only to be dealt with. The section of the trolley wire between H and the junctions of C, B, and A, will now be carrying a large current, and although it is impossible to speak definitely without particulars of the traffic, it is not unlikely that it may be seriously overloaded—at least, at times when heavy loads coincide at the station ends of A, B, and C. From the information at hand, therefore, I should say that it would be unwise to make a feeding point of H by itself, especially when taking into consideration the alterations necessary on the switchboard and the switching arrangements outside; but if such a tapping is taken I would suggest inserting a section insulator between B and A as a means of reducing the current flowing through the short stretch of trolley wire above referred to, should it prove too great.



A better, and perhaps less expensive, way of dealing with the matter would, I think, be as follows: The Board of Trade in Rule 9 state that the line must be divided into sections not exceeding half a mile in length, with arrangements provided for isolating the sections for testing purposes. This is generally complied with by bringing the adjacent ends of two trolley wire sections down to a switch box at the most convenient points, and although the Board of Trade do not stipulate it, the feeders often pass through the boxes, and are themselves provided with arrangements for isolating sections. The advantage of this mode of procedure, apart from convenience of localising a fault, is that there is no need then for more than one section of the line to be dead in the event of a short or open circuit on the line, and if the track be double, this gap caused by the dead section may be bridged over by running the car trolley pole upon the other wire, removing it, of course, when an opposing car is met with. A faulty section of the feeder also may be made dead, and the current fed along the line up to the next switch box. Now, if in the system in question section switch boxes exist, a tapping might be taken from at least one such point to each feeder (provided that the feeder follows the course of the track), the position of these points being taken as nearly as possible to correspond with X, Y, and Z in the figure. The balance of the system will now remain almost undisturbed. There will be no alteration necessary on the switchboard, as approximately the same current will return by each feeder as formerly; there will be no need for a new switch box, as existing ones may be made use of; and, finally, no section of the trolley wire will be more overloaded than in the original case.—W. G. M.

COMPANIES' MEETINGS AND REPORTS.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH.

The ordinary general meeting of this Company was held on Wednesday at Winchester House.

Sir J. Wolfe Barry, who presided, stated that during the half-year under review the unissued balance of 50,000 shares of the Company's share capital was issued to the shareholders at a premium of £3 per share, or £13 each, and an official quotation on the Stock Exchange had since been obtained. The desire of the directors, was, if possible, to reduce the cost per word by this Company's system from 4*s.* 9*d.* to a minimum of 2*s.* 6*d.* The first step—viz., a reduction from 4*s.* 9*d.* to 4*s.*—was already accomplished, and the revenue up to now had been maintained at the reduced rate. It was intended, if the standard was maintained, to make successive reductions to 3*s.* 6*d.* 3*s.*, and finally in 1903 to 2*s.* 6*d.* per word, which would be 6*d.* per word less than the minimum sum proposed to be charged by the Pacific Company. The 2*s.* 6*d.* was not fixed on in any spirit of competition, but the decision was arrived at before the Pacific Company arranged that their charge should be 3*s.* per word.

The **Marquis of Tweedale** seconded the adoption of the report and accounts (noted in our last issue), which were carried.

BRITISH ELECTRIC TRACTION.

Directors: Sir Charles Rivers Wilson, G.C.M.G., C.B. (chairman); the Right Hon. Lord Rathmore; the Hon. Sir Charles William Fremantle, K.C.B.; John Smith Raworth, M.I.C.E.; Charles S. Drummond; C. Shirreff B. Hilton; Emile Garcke, M.I.E.E. (managing director).

The interim report of the directors, dated November, 1900, states that the directors have decided to pay an interim dividend on the ordinary shares on Dec. 22 next (being six months after the last payment of dividend) at the rate of 6 per cent. per annum for the half-year ended Sept. 30 on account of the dividend for the financial year ending March 31, 1901, which is at the same rate per cent. per annum as the interim dividend paid last year. Satisfactory progress continues to be made by the Company and its associated companies, and the aggregate traffic receipts on the various lines in operation show a considerable increase. The tramways (5¼ miles) owned by the Swansea Improvements and Tramways Company were opened for traffic by electric traction on June 30, 1900, and are working satisfactorily. The receipts have increased by about 60 per cent., while the expenses of working have been relatively reduced. The Potteries Electric Traction Company, Limited, is now working 24½ miles by electric traction, and a further 4¼ miles are ready for working. The traffic receipts on all the lines are satisfactory. Since the date of the last report 3½ miles of lines of the Dudley, Stourbridge, and District Electric Traction Company, Limited, have been opened for traffic by electric traction, and a further five miles will be opened as soon as the Board of Trade have given their certificate. The traffic receipts are satisfactory. The section of the Dudley and Wolverhampton tramways from Dudley to Sedgley (2½ miles) has been reconstructed, and was opened for traffic by electric traction on Oct. 3, 1900. The electric lighting supply under the order transferred from the Kidderminster Corporation to the Kidderminster and District Electric Lighting and Traction Company, Limited, was commenced in August. The lines (four miles) owned by the Tynemouth Electric

Digitized by Google

Traction Company are practically completed, and will be opened for traffic as soon as the Corporation are ready to supply the current. Additional powers have been obtained under light railway orders granted subject to the approval of the Board of Trade as follows: Durham and Brandon, 2¾ miles; Jarrow and South Shields, 3½ miles; Morley and district, 7 miles; Spen Valley (extensions), 9 miles; Barnsley (extensions), 4½ miles. The two light railway orders for South Staffordshire granted by the Light Railway Commissioners (seven miles) have been confirmed by the Board of Trade. An Act of Parliament has been obtained for the construction and working of tramroads in the Wellingborough district (19 miles). The Peterborough order granted by the Light Railway Commissioners (5½ miles) has been confirmed by the Board of Trade. The Poole and District Electric Traction Company, Limited, has obtained an Act of Parliament for the construction and working of tramways (3¾ miles) in Christchurch and Bournemouth subject to the provision that if within a certain period the Corporation of Bournemouth under powers granted them construct that portion of the line within their borough, the Company's power to construct it shall cease, but they shall be entitled to running powers. The Kidderminster and District Electric Lighting and Traction Company has been granted a light railway order for an extension to Bewdley (4½ miles), subject to the approval of the Board of Trade. The light railway order for the Gateshead Tramways Company (2½ miles) granted by the Light Railway Commissioners has been confirmed by the Board of Trade. The application for a light railway order for extensions by the Wigan Tramways Company, Limited, has been granted in part (four miles) by the Light Railway Commissioners, subject to the approval of the Board of Trade. The South Staffordshire Tramways (Lessee) Company, Limited, has obtained a lease of the whole of the lines of the South Staffordshire Tramways Company as from Feb. 1, 1900. The provisional order granted by the Board of Trade authorising the reconstruction of the lines of the Rothesay Tramways Company, Limited for electric traction and extension of tenure has been confirmed by Parliament. The provisional order authorising tramways (3½ miles) granted by the Board of Trade to the Weston-super-Mare and District Electric Supply Company, Limited, has been confirmed by Parliament The provisional order granted by the Board of Trade authorising (*inter alia*) the reconstruction by the Leamington and Warwick Tramways and Omnibus Company, Limited, of the company's tramways within the borough of Warwick has been confirmed by Parliament. The Bills promoted in the last session of Parliament by the Electrical Power Distribution Company, Limited, for the supply of electric energy in bulk in the county of Durham and North Metropolitan areas have both been passed, and the Acts of Parliament have received the Royal assent. The Board of Trade have approved the transfer to the Company of the following electric lighting orders from the authorities who obtained them: Hertford Local Authority, Lewes Local Authority. The following electric lighting provisional orders granted by the Board of Trade have been confirmed by Parliament: Banbury, Jarrow, Sevenoaks, Sheerness, Staines, Egham, and Chertsey, Wallington, Wellingborough. The applications for light railway orders at Blyth and Windermere have been withdrawn for the time being. The Light Railway Commissioners declined to grant the order applied for in respect of Kingston and Surbiton.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN

Salford.—Tenders for the electric lighting of the town hall, Pendleton, will be called for shortly.

Kendal.—The Corporation invite tenders for the supply and erection of various plant. Tenders by Dec. 1. Details in our advertisement columns.

Bristol.—The Electrical Committee invite tenders for electric travelling crane and condensing plant. Tenders by Nov. 22. Details in our advertisement columns.

Farnworth.—The Urban District Council invite tenders for the wiring of premises on a deferred payment system. Tenders by Nov. 12. Details in our advertisement columns.

Newcastle-upon-Tyne.—The New Tramways Committee invite tenders for arc lamp cables, telephone and pilot wires. Tenders by Nov. 21. Details in our advertisement columns.

Newcastle-upon-Tyne.—The New Tramways Committee of the Corporation invite tenders for arc lamps and accessories. Tenders by 21st inst. Details in our advertisement columns.

Belfast.—The Gas and Electric Committee invite tenders for switchboard extensions. Specifications, etc., may be obtained on application to Mr. Victor A. H. McCowen, city electrical engineer. Tenders by Nov. 23.

Nottingham.—Tenders are invited for the installation of an electric lighting plant at the new workhouse. Specifications may be obtained from Mr. G. Muncaster Howard, clerk, Poor-Law Offices, Nottingham.

West Bromwich.—The Corporation invite tenders for the supply of wiring materials, motors, and labour in wiring for lighting and power installations. Tenders by Nov. 17. Details in our advertisement columns.

Wolverhampton.—The Tramways Committee invite tenders for erection of car depôt, paint and repair shops, etc., at Cleveland-road. Plans, etc., may be seen at the office of Mr. J. W. Bradley, C.E., M.I.M.E., borough engineer, Wolverhampton. Tenders by Nov. 19.

Cardiff.—The Corporation invite tenders for the following: (Section 4) 75-kw. motor-generator and Tudor storage battery; (5) lead-covered cables; (6) 20-ton travelling crane. Tenders by Nov. 28. Details in our advertisement columns.

Watford.—The Urban District Council invite tenders for materials for and the construction of a boiler setting at their electric lighting station. Specification, etc., may be seen at the offices of Mr. D. Waterhouse, 14, High-street, Watford. Tenders by Nov. 15.

Greenwich.—The Guardians invite tenders for proposed electric lighting installation at the new workhouse, Grove Park, S.E., now in course of erection. Specification, etc., may be obtained and plans seen at the Greenwich offices of the architect, Mr. Thomas Dinwiddy, F.R.I.B.A. Tenders by Nov. 22.

Walker (Northumberland).—The Urban District Council invite tenders for the erection, complete, exclusive of buildings, of a two-unit dust destructor of the Meldrum type, etc. Specifications can be obtained from the engineers, Messrs. Handcock and Dykes, 1, Victoria street, Westminster, London, S.W. Tenders by Nov. 13.

London (City).—The Streets Committee of the Corporation invite tenders for the hiring of a mechanically-driven dust-cart for collecting and removing the dust, trade refuse, and street sweepings from the City to the Corporation's depôt at Lett's Wharf, Commercial-road, Lambeth, S.E. Tenders by Nov. 10. Details in our advertisement columns.

Shoreditch.—The Vestry invite tenders for the supply of various plant for the new generating station at Whiston-street, including direct-connected direct-current generators of an output of about 800 kw. each set. Specifications, etc., may be obtained at the office of the Vestry's electrical engineer, Mr. C. Newton Russell, Electric Light Station, Coronet-street, Hoxton, N. Tenders by Nov. 20.

Stockport.—The Tramways Committee invite tenders for the overhead equipment and supply of rail bonds for six sections of their electric tramways, having a total length of about 2 miles 3 furlongs 5 chains double line, and 2 miles 2 furlongs single line. Specifications, etc., may be obtained from Mr. A. J. H. Carter, electrical engineer, or Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Stockport.—The Tramways Committee invite tenders for the laying of the permanent way of their electric tramways, including concrete foundation, but excluding bonding and paving, in six sections, having a total length of about 2 miles 3 furlongs 5 chains double line, and 2 miles 2 furlongs single line. Plans, etc., may be obtained on application to Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul-General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

London, S.W.—The London County Council invite tenders for the supply, within 10 weeks of the order being given, of about 150 arc lamps, required in connection with the electric light installation for the Victoria-embankment and Westminster Bridge. Approximately, 80 of the lamps will be for current of 10 to 12 amperes, and 70 for current of 5 to 6 amperes. The lamps will be run in both cases 10 in series, and the supply will be from one or more dynamos, the pressure available being from 460 to 480 volts. Each person tendering will be required to submit a drawing of the kind of lamp which he proposes to supply, showing details of construction, and the materials to be used. Specifications, etc., may be obtained at the Engineer's Department, County Hall, Spring-gardens, S.W., upon payment of £1. Tenders by Nov. 13.

RESULTS OF TENDERS:

Limerick.—The tender of Mr. Bourke, Carr-street, has been accepted for erecting at the gasworks a generating station for electric lighting, at £2,680.

Middleton (Lancs.).—The Corporation have accepted the tender of Messrs. Partington and Sons, Middleton, at £5,950, for the erection of electricity buildings.

London County Council.—The Council have accepted the tender of Messrs. Barlow Bros. and Co., at £260, for the wiring and fittings required at the fire station in course of erection at Shepherd's Bush.

Whitby.—The Urban District Council have accepted the tender of the Callender's Cable and Construction Company, Limited, for the supply, delivery, and fixing of conduits, cables, boxes, lamps, and posts, at £5,327. 5s. 8d.

Sheffield.—The tender of the Electrical Construction Company, Limited, of Wolverhampton, for the two new two-phase alternators and engines for the sum of £13,840, and for the alteration of the existing single-phase plant at schedule prices, has been accepted.

London, S.E.—The Strand District Board of Works have accepted the tender of the Alliance Electrical Company, Limited, London, at £540, for the construction, delivery, and fixing of an engine and dynamo, switchboard, etc., for their destructor works, Shot Tower Wharf, Commercial-road, Lambeth.

Digitized by Google

Beetle.—The following contracts have been entered into by the Corporation for electric traction purposes in Knowsley-road: R. W. Blackwell and Co., £1,100; Callender's Cable and Construction Company, £210; Leeds Steelworks, together with cost incurred by the Corporation in laying rails, £2,924.

Warrington.—The Electric Lighting Committee have accepted the following tenders: Venner and Co., 200 meters to be delivered within 12 months from acceptance of tender, according to schedule prices; the Reason Manufacturing Company, Limited, 200 demand indicators; the Warrington and District Electric Light and Power Company, Limited, installation of electric light mains and fittings at the generating station and central sanitary depôt, at £354. 2s.

Salford.—The following tenders have been accepted: Cables—(Section 1) Western Electric Company, (2) British Insulated Wire Company, (3) Western Electric Company, (4) St. Helens Cable Company, (4, part) W. T. Glover and Co., (5) St. Helens Cable Company, (6) W. T. Glover and Co.; rubber solution and strip, Baxendale and Co.; black tape and binding wire, St. Helens Cable Company; fine solder, jointers' metal, etc., British Insulated Wire Company; cast-iron boxes and brass fittings, Lancaster and Tonge; wrought-iron pipes and bends, Clydeside Tube Company.

Cardiff.—The following tenders have been received by the Tramways Department of the Corporation:

Section No. 3.—Boilers, etc.

V. Coates—boilers, £3,700; Vicars stokers, £730; Bennis stokers, £650; conveyor, £170; elevator, £160; bunkers, £800; economisers, £530; superheaters, £440; water-tank, £500; pumps, £390.

Evans—boilers, £2,900; Vicars stokers, £750; Bennis stokers, £625; conveyor, £180; elevator, £150; bunkers, £800; economisers, £510; superheaters, £585; water-tank, £525; pumps, £350.

Galloways—boilers, £3,040; Vicars stokers, £720; Bennis stokers, £628; conveyor, V. £168, B. £288; elevator, V. £138; bunkers, V. £966, B. £804; economisers, £530; superheaters, £620; water-tank, £560; pumps, £370.

Meldrum—boilers, own make; Bennis stokers, £705.

Musgrave—boilers, £2,952 (accepted); Vicars stokers, £685; Bennis stokers, £595; conveyor, V. £159. 10s., B. £280; elevator, V. £131. 10s.; bunkers, V. £917, B. £762; economisers, £512 (accepted); superheaters, £558 (accepted); water-tank, £698 (accepted); pumps, £395 (accepted).

Tinkers—boilers, £2,940; Vicars stokers, £725; elevator, £138; bunkers, £965; economisers, £550; superheaters, £590; water-tank, £720; pumps, £380

Yates and Thom—boilers, £2,877; Vicars stokers, £753; Bennis stokers, £605; conveyor, V. £305, B. £288; bunkers, V. £958, B. £800; economisers, £530; superheaters, £566; water-tank, £581; pumps, £378.

Danks and Co.—boilers, £2,767. 10s.; Bennis stokers, £623. 14s.; conveyor, B. £286; bunkers, B. £798. 1s.; economisers, £530; superheaters, £450; water-tank, £495; pumps, £371.

Vicars (direct)—stokers, £684. 19s. (accepted); conveyor, £159. 10s. (accepted); elevator, £131 (accepted); bunkers, £917 (accepted).

Messrs. Tinkers's tender reduced £965 if Bennis stokers are used.

Perth.—The Commissioners have received the following tenders for supply of electric cut-outs: Hands, Limited, 21, Garlick-hill, Cannon-street, London, E.C., cut-outs, two-wire, 0 to 10 amperes carrying capacity, 8s. each, 10 to 25 amperes 11s., 25 to 50 amperes 12s. 6d., 50 to 75 amperes 15s., 75 to 100 amperes 18s. (accepted).

London County Council.—The Council have received the following tenders with regard to the wiring and fittings required in connection with the electric lighting of the fire station in course of erection at Redcross-street, City:

Barlow Bros. and Co. (accepted)	£270	0	0
Electric Lighting Corporation, Limited	305	0	0
G. E. Taylor and Co.	320	0	0
F. A. Glover and Co.	321	0	0
Tamplin and Makovski, Limited	375	0	0
E. S. B. Harrison and Co.	440	1	0

BUSINESS NOTES.

TRACTION.

Buxton.—The rent for meters has been reduced to 2s. 6d. per quarter.

Perth.—The tramway company have refused the offer of the Town Council to purchase the tramways.

London County Council.—The Fire Brigades Committee are considering the advisability of employing motors instead of horses.

Warrington.—Application is to be made to the Board of Trade by the Town Council for permission to construct certain tramways in the town.

Bolton.—The electric tramways, which are worked by the Corporation, have made a profit of £12,151. 11s. 6d. upon the last six months' working.

Erdington.—A committee is to be appointed with the power to obtain expert advice and to consider and report upon the best system of tramways to be constructed, and the roads along which they should be laid.

Folkestone.—At a public meeting on Friday the subject of the proposed tramways (details of which appeared in our last issue) was discussed, and a resolution passed in favour of the scheme. A poll was demanded.

Audenshaw.—Notice is to be served upon the Manchester Carriage and Tramways Company for the purchase, under the Suburban Tramways Act, 1879, of so much of their undertaking, including material and plant, as goes through the township of Audenshaw.

Huyton.—At the last meeting of the District Council the proposed branch of the South Lancashire tramways through Roby and Huyton was again discussed, and it was decided that the scheme be opposed until the line along the Liverpool-road had been constructed.

Brighton.—At the clearing-up meeting of the Town Council last week a motion to amalgamate the Electric Lighting and Tramways Committees was moved, but was withdrawn on the balance of opinion appearing to favour the keeping of the two committees separate.

Cheap Tramcars.—When the Sheffield Tramways Committee sold six of their old vehicles last week, one in fairly good condition fetched 25s, another £2. The best realised only £4. 2s. 6d., although it had cost originally about £100. These prices were exclusive of under-carriage and wheels.

Birstall.—A letter from the British Electric Traction Company suggesting that the District Council should purchase the portion of the Dewsbury, Batley, and Birstall tramway within its district, and lease the same to the traction company for 28 years, will come before the next meeting of the District Council.

Glasgow.—The Tramways Committee of the Corporation have agreed that additional borrowing powers should be obtained for £1,250,000 to cover the cost of constructing and equipping the authorised and proposed tramway lines, and also of completing the conversion of the existing lines, including cars, power stations, etc.

Paisley.—Polling took place on Saturday on the question whether the Corporation should promote a Tramways Bill or support private enterprise in carrying out a tramways undertaking for the town and district. The result was announced as follows: private enterprise, 3 616; Corporation Bill, 2,022—majority, 1,594.

Aberdeen.—The Tramways Committee of the Town Council have decided to allow a section of line to be laid down on the surface contact system as an experiment. The length of the experimental track will be about 600 yards, and Messrs. M'Elroy and Grunow, if the line is successful, are to sell it to the Town Council for £1,400.

Wrexham.—Mr. Trentham has been in communication with the National Electric Traction Company, Limited, 66, Victoria-street, London, as promoters of the tramways, and he is of opinion that a traction feeder, at the cost of the tramway company, would have to be laid to Ruabon-road by way of Madeira-hill and Poplar-road.

Lytham.—Negotiations are proceeding between the Blackpool Corporation and the Blackpool, Lytham, and St. Annes Tramway Company for the purchase of the latter's undertaking, and it is

Digitized by Google

stated that there is not a very great difference between the respective amount the Council is prepared to give and the company to accept for the concern.

Wolverhampton.—At a special meeting of the Town Council last week a report from the Tramways Committee containing recommendations as to the lines of route which should be first taken in hand for construction for the future working of the tramways on the electric traction system in place of the present horse traction, was adopted.

Burton.—The sub-committee of the Town Council appointed to deal with the proposed tramways for Burton have adopted the reports of the borough surveyor and Mr. J. E. Waller. The scheme includes the laying of tramways in six different directions in the town. As to the motive power to be used the committee leave the Town Council to decide.

Turton.—The Bolton Corporation Tramways Committee not being prepared to make any offer with regard to any tramways proposed to be constructed in Turton, the clerk is consulting Mr. Ball the Urban District Council's parliamentary agent, as to the proposals of the South Lancashire Tramways Company with regard to tramways and light railways in Turton.

King's Norton.—The Urban District Council have proposed to promote a Bill in Parliament or apply for a provisional order to authorise the Council to construct and work and to lease or sell certain tramways and light railways along the Bristol-road, Pershore-road, and other roads, and for granting other powers in relation to tramways within the district of the Council.

Kent.—The authorities of the districts from Plumstead to Dartford have agreed to ask for powers for an electric tramway. The proposed line will run from the existing metropolitan system at Plumstead through East Wickham, Welling, Bexley Heath, Crayford, and Dartford. Both the Dartford and Bexley urban authorities have the electric supply in their own hands.

Fulham.—At the final meeting of the members constituting the Vestry, a communication was received from the London County Council notifying their intention to introduce a Bill in the next session of Parliament for powers to construct tramways along the King's-road, Fulham, to and over Putney Bridge. The Vestry sanctioned the affixing of the usual notices to the lamp-posts.

Hull.—Lieutenant Colonel Von Donop, R.E., has made an inspection of the Spring-bank route of the Hull Corporation's system of tramways. The city engineer (Mr. White) has been instructed to lay the rails for electric cars along the Hedon-road, and to repave the road with wood as far as the sanatorium. The plant at the station is to be increased by additional engine, boilers, and dynamo.

Bristol.—A number of new electric lines are shortly to be placed at the service of the public in Bristol. Many lines have recently been converted from horse to electric traction, and some are of entirely new construction. Some 250 new cars have been built for this service, and the cars are to run from about 5 a.m. to 12 midnight. It is proposed to use the tram horses for omnibuses which are to run to and from the various electric tramways.

Llanelly.—The Light Railway Commissioners last week held an enquiry into the scheme formulated by the Llanelly and District Electric Lighting and Traction Company, which was approved of by the Borough Council and all other local public bodies. The Chairman, at the close of the enquiry, remarked that the scheme appeared to be an excellent one, and that the Commissioners would have great pleasure in recommending it to the Board of Trade.

Reading.—Notice to purchase has been served on the tramways company, and has been acknowledged by them. The Corporation have made a formal offer of £10,105, and have informed the company that in the event of the offer not being accepted within a month from the date of making the same, the offer will be regarded as declined, and an application will thereupon be made by the Corporation to the Board of Trade to appoint a referee pursuant to Section 43 of the Tramways Act, 1870.

West Bromwich.—At Wednesday's meeting of the Town Council the General Purposes Committee reported that they had now arranged terms by which the tramways when acquired should be leased to the South Staffordshire Company for a term of 21 years (to be extended to 30 years if the authority of Parliament be obtained) upon satisfactory terms under which the Corporation would reconstruct the tramways and equip them electrically with overhead traction, the company taking from the Corporation the supply of electrical energy required.

Birmingham.—The accounts of the tramway department for the half year ending Sept. 26 show a surplus between income and expenditure of £12,151. 4s. 6d. The expenditure includes a sum of £6,385. 6s. 6d. for interest and sinking fund, and £3,610. 4s. 9d. for repairs of all kinds. Thus in the general statement the income is £35,762, and the expenditure £23,610. The details of the working expenses are for management £807, for traffic £10,988, and for rent, rates, and taxes £1,677. The repairs and maintenance expenses include: rolling stock £2 567, electrical equipment £230, permanent way £813, and miscellaneous expenses £143—making a total for works expenses of £17 225.

New Issue.—The London United Tramways Company, Limited, are issuing £550,000 4 per cent. first mortgage debenture stock, of which £34 125 is reserved for allotment to the holders of existing terminable debentures, and the remaining £315,875 is offered for public subscription at par. The company was incorporated in 1894 with a capital of £600,000, £350 of which has been called up, and they have powers for the construction of electric tramways in the western districts of London. The first portion of the scheme to be carried out comprises 16 miles of route, of which 11 miles have already been completed and are about to put into operation electrically; the remaining five miles are in course of construction.

Manchester.—A special meeting of the City Council will be held on Dec. 5 to consider and decide "whether the Council shall exercise its right, under the powers conferred by Section 43 of the Tramways Act, 1870, to require the Manchester Carriage and Tramways Company to sell to the Corporation so much of the undertaking authorised by Part II. of the Manchester Carriage and Tramways Company Act, 1880, as the Lord Mayor, aldermen, and citizens of the city of Manchester are under the said 43rd section entitled to purchase"; and to consider an agreement to be produced at the meeting made under the provisions of the Manchester Corporation Tramways Act, 1900, fixing a date for the accruer of the right of purchase, also to adopt, if so decided, a resolution by which the sale will be required after the approval of the Board of Trade has been obtained.

William Griffiths and Co., Limited.—This Company has been formed, with a capital of £200,000, to acquire and carry on the well-known business of William Griffiths, stone and granite merchant, contractor for paving works in stone, wood, and asphalte, tramway construction, municipal works, and other works of a similar nature, carried on at Hamilton House, Bishopsgate-street (London), Hoxton, Islington, Bethnal Green, and elsewhere, and the business of William Stranger, quarry owner, Guernsey, which has been worked in connection therewith. The business of William Griffiths has been established for upwards of 70 years, and amongst its more important customers are H.M. Government, the Corporation of the City of London and other corporations, the London County Council and other county councils, and municipal authorities, also railway, gas, water, tramway, electric lighting, and other public companies.

Normanton.—Some time ago the Urban District Council decided to oppose the application of the North British and Northern Counties Electric Supply Companies for a provisional order to supply the town with electric light by making application for an order themselves. Since then the Council met a deputation from the United Kingdom Tramway, Light Railway, and Electrical Syndicate, Limited, of Westminster, who have a scheme in hand for connecting Normanton, Castleford, Pontefract, and Knottingley with electric tramways and electric light, and the proposed area will include Altofts, Whitwood, Fryston, Featherstone, Sharlston, Streethouse, Snydale, and Warmfield. It is intended to form a sub-company, to be named the West Riding Company, and the offices will be at Leeds. The maximum rate for the tramways will be 1d. per mile for ordinary passengers and ½d. per mile for workmen's cars, and the maximum price for lighting is to be 4d. for public and 6d. for private use per unit. The syndicate will also undertake the conveyance of goods by night. The Council favour this scheme on condition that Altofts was connected instead of Featherstone, and on the consent of the other authorities being obtained, the work will be proceeded with on license pending the granting of the provisional order.

Bradford.—Lieut.-Colonel Von Donop last week inspected the two new tram routes belonging to the Corporation, which are now ready for operation. The first of these, known as the Whetley Hill tramway, extends from Godwin-street, in Westgate, to Duckworth-lane, and is 1 mile 922 yards long. The other line runs from Thornbury to the Leeds city boundary at Stanningley. On the new Whetley Hill section during Friday, Saturday, and Sunday, traffic on the first named day not being begun until half an hour after noon, and with five cars only at disposal on the route at present, a distance run of 762 miles produced receipts of £80. 1s. 4d., or 25 21d. per mile. The returns of the working of the other Bradford electric tramways for the week ended Nov. 4 show that on the Bolton section 3,099 miles have been run, and that the receipts amount to £136. 16s. 1d., which is equal to 10 59d. per car mile. The workmen's cheques issued numbered 1,490, and 1 498 were returned. The total receipts since April 1 amount to £4,716 7s. 5d., or 11·38d. per car mile. On the Horton section during the past week 6,309 miles were run, and the receipts were £285. 6s. 5d., equal to 10·85d. per car mile. The workmen's checks issued numbered 1,764, and 1,793 were returned. The total receipts since April 1 amount to £10,205 6s. 6d., or 12 09d. per car mile. On the Lidget Green section 2,720 miles were run during the past week, and the receipts were £128. 14s. 4d., equal to 11·35d. per car mile. The total receipts up to date have been £1,266. 17s. 8d., equal to 11 65d. per car mile.

Sheffield.—The Heeley route has been opened for traffic. The minutes to be presented at the Council meeting to-day include those of a joint meeting of the Finance and Consultation Sub-Committee of the Improvement Committee, the Audit Sub-Committee of the Highway Committee, and a sub-committee of the Tramways Committee, which has been held to consider the cost of street widenings and works necessitated through tramways construction. The Joint Sub Committee recommend that the following principles of adjustment be adopted between the Tramways and Improvement Committees as to purchases of properties for tramway construction and street improvements: (1) In case of street widening entirely and solely for tramway construction, which otherwise would not be done, the Tramways Committee to bear a proportionate share of the cost; the amount to be adjusted by the two committees. (2) In case of street widening where it is partly required for street improvement and partly for tramway construction, the Tramways Committee to bear a proportionate share of the cost; the amount to be adjusted between the two committees. (3) In case of street widening where it is entirely and solely for street improvement, irrespective of any contemplated tramway con-

Digitized by Google

struction which may hereafter be carried out, the Tramway Committee not to bear any proportion of cost of such widening. The Tramways Committee recommends increases of wages of the staff at the power station; also that the general manager and the city surveyor report on the facilities of the Fitzalan Market as a central tramway station, and that power be obtained to take over the whole of the Fitzalan Market for use as a central station, and that the Finance Committee be asked as to the amount required to buy the same. At a recent meeting of the Tramways Committee the city surveyor reported that the following routes are now in hand, being part of the work ordered for the year 1900-1: Hillsborough route (*via* Nursery-street) to Hillsborough-park; Western Bank to Crookes (*via* Whitham-road); Darnall route (Staniforth-road and Pinfold-lane). The city surveyor also reported that the following is a list of the routes (not yet started) to complete work ordered for year 1900 1: Broomhill to Nether Green *via* Fulwood-road; Shalesmoor to Hillfoot Bridge *via* Penistone-road; Intake route extension (cemetery to Intake). The sub-committee recommend that the following routes be put in hand as soon as the work already agreed to be done is completed: Page Hall-road and Upwell-street; Newhall-road; Rustlings-road, Hunter's Bar to Nether Green; Carlisle-street to Grimesthorpe; junction of Glossop-road and Hounsfield-road along Clarkehouse-road and Brocco-bank to connect with Ecclesall-road; Ecclesall-road, Hunter's Bar to Ecclesall Church; Cemetery-road to Ecclesall Church *via* Cemetery-road and Psalter lane. That the route from Nether Edge terminus along Sheldon-road, to connect with Abbeydale-road, be commenced as soon as the road is properly constructed. That the portion of the road from the bottom of Crookes-road to Broomhill (bottom of Manchester-road) be electrically equipped, so as to commence running cars to Broomhill as soon as the route is ready for running.

LIGHTING AND GENERAL.

Gibraltar.—Wireless telegraph stations are to be established here and at Malta.

Kingston.—Low-tension mains will be laid in Brunswick-road and also in a portion of Coombe-road.

Keeles.—A new feeder cable is to be obtained at an estimated cost of £515 to cope with the present demand.

Maidenhead.—The Council have decided to hold a special meeting on Nov. 14 to discuss the subject of electric lighting.

Birstall.—The District Council have decided to apply for an order authorising them to supply electric light and power within their district.

Kidderminster and District Electric Lighting and Traction Co.—The transfer-books and register of members will be closed from 7th to 15th inst. inclusive.

Chapel Royal.—The Chapel Royal, St. James's Palace, is to be lighted in future by electricity. The work will probably be completed within the next fortnight.

Bridgwater.—On Friday Colonel A. J. Hepper held an enquiry into the application by the Town Council for powers to borrow £20,000 for purposes of electric lighting.

Wellingborough.—The refuse destructor is now approaching completion. The Council have decided to apply for an order enabling them to carry out their electric lighting scheme.

Theft of Wire.—Arthur Green, a labourer employed by the City Electric Lighting Company, was charged with theft of electric cables at Southwark Police Court, and remanded for a week.

Folkestone.—The sub-committee have prepared a report of their proceedings in connection with the application of the National Telephone Company for permission to put their lines underground.

Sale of Plant.—The Corporation of West Ham and Messrs. Mather and Platt are advertising sales of gas-engines and of dynamos respectively, details of which appear in another column.

Belfast.—The license which the Postmaster-General is prepared to grant to the Corporation for the establishment of a municipal system of telephones in the telephone area of Belfast extends into Down.

"The London Technical Education Gazette."—The last number (September and October) contains a detailed list of evening classes that are conducted in London during the session 1900-1.

London Gazette.—Notices of intention to apply for orders have appeared in the *Gazette* as follows: Electric lighting—Friern Barnet Urban District Council and Cannock Urban District Council.

Holyhead.—The experts who examined the force of water running through Pont Lusinwan with a view of setting plant to generate electricity have guaranteed sufficient power to generate 25 000 c.p.

Guildford.—A tracing of the route of the supplementary mains proposed to be laid by the Electricity Supply Company in the eastern portion of the town has been referred to the Paving Committee.

Otley.—The Urban District Council have instructed Mr. G. Wilkinson, electrical engineer, of Harrogate, to conduct an enquiry and submit a scheme for the lighting of the town by electricity.

Columbia Motorcar Co., Limited.—This Company has been registered with a capital of £1,000 in £1 shares, the object being to manufacture, sell, let on hire, and deal in electric motors, etc.

Stockton.—At a meeting of the Town Council on Nov. 6 it was reported that by the end of the month the electric lighting works would be completed so far as to enable the light to be turned on in the streets.

Partnership.—Mr. Haydn T. Harrison, M.I.E.E., has taken into partnership Mr. F. S. Pillean. The name of the new firm is Haydn Harrison and Co., having offices at 11, Victoria-street, Westminster, S.W.

Electrical Trades Supply, Limited.—This Company has been registered with a capital of £5,000 in £1 shares, the object being to carry on at Birmingham or elsewhere the business of electric appliance manufacturers, etc.

Automatic Telephones.—The Victorian postal authorities are perfectly satisfied with the income earned by automatic telephones. During the 12 months the sixpence-in-the-slot instruments have been in use they have earned £127. 6s. 3d.

Pocklington.—The Urban District Council have decided to send a deputation to the Northallerton electrical works, with a view of considering the advisability of the installation of a similar plant for electric lighting purposes at Pocklington.

Pickering.—The Urban District Council have passed a resolution assenting to an application to the Board of Trade by an electricity supply company for an order empowering them to establish works for supplying electricity in the urban district.

Accident.—There is nothing like leather, for when a 60ft. telegraph pole fell at Southampton recently while a wireman in the employment of the General Post Office was working on it, the man, who was strapped to the top of the pole, escaped without injury.

Wellington.—The District Council have resolved to apply to the Board of Trade for a provisional order authorising them to supply electricity for all public and private purposes within the Council's district. Mr. T. L. Miller, of Liverpool, is the consulting engineer to the Council.

London Electric Warehouse Co.—This Company has been registered with a capital of £1,000 in £10 shares, the object being to carry on the business of electrical engineers, electricians, suppliers of electricity, manufacturers of and dealers in electrical machinery, plant, apparatus, etc.

Walton.—The Urban District Council do not approve the application of Edmundson's Electricity Corporation for a provisional order, and have referred it to a committee of the whole Council to consider whether they should not themselves take the necessary steps to apply for an order.

Yorkshire Electric Power Syndicate, Limited.—This Company has been registered with a capital of £10,000 in £10 shares, the object being to carry on in the West Riding of Yorkshire, south of the River Wharfe, or elsewhere, the business of an electric power supply company in all its branches.

Portsmouth.—The Town Council have adopted a report of the Finance Committee recommending the adoption of the smaller scheme for the establishment of a municipal telephone exchange mentioned in Mr. Bennett's report, and the appointment of Mr. Bennett as consulting engineer at a fee of 5 per cent. on the outlay.

King's Norton.—The Urban District Council have passed a resolution in the following form: "That the Council do take into consideration the desirability of proceeding with the powers to establish electric lighting undertaking under the powers of the provisional order obtained in 1898, and that instructions be given for the preparation of the plans; and, further, that the clerk inform the Board of Trade of the action taken, and do apply to them to allow a further period before considering the question of revoking the order."

Camera Club.—At the meeting on Thursday night last week Mr. James Cadett, lecturing on the latest in X rays, gave an account of his experiments with X ray tubes in regard to their behaviour to photographic plates or sensitised papers. He also, with the assistance of Mr. Cook, turned the current through a number of tubes, demonstrating how the electric current refuses to penetrate the dark spot in the tube, supposed to be the place where the highest vacuum exists, and follows the walls of the tube or the gaseous matter near them. This was most remarkable in the case of tubes with considerably elongated ends, forming a spiral course of perhaps 20 times the distance between cathode and anode. He also found, when applying the wire to the most distant ends of a tube of moderate vacuum and disconnecting the anti cathode that, contrary to the generally adopted theory, the current flowed twice as easily as before. An interesting debate ensued, and afterwards some pretty specimens of fluorescence were shown.

Appointments Vacant.—Applications are invited for the post of manager and engineer to the Portsmouth Corporation telephone exchange.—The Cardiff Corporation have vacancies for a chief assistant engineer to the electrical tramway engineer, and an electrical mains superintendent.—Assistant engineers are also wanted at Newcastle under-Lyme and at Bolton.—The Electricity Department of Aberdeen require a junior station assistant, salary commencing at 30s. per week. Applications, stating age, etc., to be sent by 14th inst. to Mr. J. Alex. Bell, city electrical engineer, Cotton-street, Aberdeen.—The Warrington Electric Lighting Committee are about to advertise for an electrical engineer at a salary of £250 per annum.—A resident electrical engineer is also required at Barking Town, Essex. Particulars of these vacancies and others relating to articled pupils, draughtsmen, jointers, etc., will be found in our advertisement columns.

Digitized by Google

West Bromwich.—The Electric Lighting Committee have received 64 applications for the position of borough electrical engineer, and will recommend that Mr. J. H. Wray, of Blackpool, be appointed, at a commencing salary of £250 per annum. The construction and laying down of the works and mains is now well in hand.

West Hartlepool.—At the monthly meeting of the Town Council on Tuesday the Council accepted a recommendation of the Finance Committee that the services of an expert be engaged to report on the desirability and cost of installing a municipal telephone service in the town. Mr. J. G. Steel was appointed assistant electrical engineer.

Skipton.—With regard to the proposed electric light supply for the town we learn that 281 circulars have been sent out by the Council. Of these 90 replied assenting to the Council's proposal, 95 refused, and 96 have not yet replied. No price has been fixed at present. It is stated that next week everything will be ready for the application for an order.

Blairgowrie.—When a number of years ago the Ericht linen works were lighted by electricity, steam was the motive power. Water power has, however, now been adapted by means of the water-wheel at the "Muckle Mill." Messrs. Lowdon, electricians, Dundee, superintended the operations, and the dynamo and shafting were supplied by Mr. Abercrombie, engineer, Blairgowrie.

Wolverhampton.—The annual report of the Lighting Committee, which will be submitted to the Council to-day, states that the profits during the year had amounted to £402. 6s. 11d. The demand for electricity continued to increase, and extra machinery was being put down. The units sold to private consumers during the 12 months to Sept. 29 last were 653,216, as against 331,203 in the previous year.

Bristol.—A proposal to extend several mains has been accepted. The committee have decided to carry out Sir Benjamin Baker's recommendation that the foundations of the new electric lighting station should be strengthened by buttresses instead of cross walls. In recommending this the engineer pointed out that the buttresses would involve less expenditure than walls, and would achieve the object in view.

Elland.—Unless a move is made shortly toward the construction of an electric installation, the Council will be in danger of losing the powers conferred upon them some time ago by the granting of an electric lighting provisional order. The negotiations are at present in progress as to a proposed site, and until some definite arrangement has been made with Mr. Lipscomb, Lord Savile's agent, little more can be done.

Walmer.—The Electric Lighting Committee have been discussing a report of an electric lighting installation at a cost of £60,000, which would show an annual profit of £2,000. It has been left to the committee to confer with Deal in order to ascertain what steps that Council are going to take, the Walmer Council being of the opinion that, to make it a paying concern, it could only be done jointly between the two places.

Newport.—The Electrical Committee of the Council have adopted a report in favour of the free wiring of private residences in the borough. The present rate per unit for lighting purposes is from 5d. to 6d.; but where an outlay is made for wiring the premises the charge will be 6d. to 7d. per unit. The kind of fittings, too, are prescribed, and should the householder require very elaborate or ornate fittings he will have to pay the difference.

Beetle.—The Town Council have agreed that, pursuant to the sanction of the Local Government Board to the borrowing of £19,819 for the purposes of electric lighting, the Finance Committee be authorised to take up on loan the following sums: for electric lighting purposes in Linacre lane and Hawthorne-road, £1,662; for the same purposes in Stanley-road, £790; and for Derby-road, Rimrose-road, Knowsley-road, and Marsh-lane, £6 855.

Sam Deard's Glazing.—We learn that Sam Deard's patent glazing system has been adopted for the Wantage Engineering Company, Limited, workshops, boiler and sanitary buildings, etc., at Wantage; also at Tendring, near Colchester, for the workhouse buildings, for new warehouse roof at Dawson-street, Dublin; and also for the new electric light buildings at Chelmsford. The patentee's works are at Harlow, Essex, and London offices, 34, Old Broad-street, E.C.

Plumstead.—At a special meeting of the Vestry on Friday a report was adopted from the Lighting Committee on the provision for electric lighting, which recommended that tenders be accepted, amounting to a total of £36,816 16s. 10d., for various works in connection therewith. It was also resolved that detailed plans be furnished to the County Council as early as possible, and that the Borough Council be requested to expedite the scheme for electric lighting and the dust destructor.

Government Telephones.—At the Court of Common Council on Thursday a letter was read from the Postmaster-General relative to the excavations in the City for the purpose of laying telegraph and telephone pipes, and stating that in the more important thoroughfares the work had been carried on day and night whenever practicable without infringement of the restrictions imposed by the city engineer, and that the work would be continued to be pushed on as rapidly as possible.

Glover's Sports.—Glover's Salford Works played Glover's Trafford Park Works on Saturday, the parent works being defeated by nine goals to nil. A combined works club was formed after the game with the special object of promoting matches (or, if possible, a football league) among the electrical engineering works in Manchester and district. The hon. secretary, Mr. W. G. Tickle, will be glad to receive challenges or communication to this end. Address, Springfield Cable Works, Salford.

Westinghouse Co.—We have received from the British Westinghouse Electric and Manufacturing Company, Limited, a copy of their circular No. 1,034, which deals with the direct-current engine-type generators at 250 volts which are manufactured by the firm. The generators are more particularly constructed for supplying power to machine tools, cranes, pumps, etc. As is usual in these circulars, the machines are described in detail, and illustrations and diagrams are given, as are also tables giving the standard sizes and approximate dimensions of the generators.

Strike.—The strike of tramway men at Ashton-under-Lyne ended on Saturday. The men on strike returned to work pending the Board of Trade arbitration on the points in dispute. The free labour men who took the places of the strikers five weeks ago, when this dispute began, have been paid up and granted a bonus. The arbitrator, the company, and the men's representative have agreed that the arbitration shall take place at the Ashton Town Hall on the 15th inst. On Saturday two men were charged with assaulting police officers, and were each fined £1 and costs or a month's imprisonment.

Airdrie.—The amended draft agreement between the Council and the Scottish House-to-House Electricity Company, Limited, as to electric lighting of the streets will come before the Town Council next month. The draft is divided as follows: (1) agreement as to the Tramway Act obtained by the New General Traction Company, Limited, in last session of Parliament; (2) conditional agreement for the transfer of powers, duties, and liabilities of the Airdrie Burgh Electric Lighting Order, 1898; (3) agreement transferring powers, duties, and liabilities of the Airdrie Burgh Electric Lighting Order, 1898; and (4) agreement for public lighting.

Cardiff.—Members of both the Cardiff Electric Lighting and Tramways Committees met at the town hall on Monday to consider a suggestion that the two committees should be amalgamated. After discussion, the question of amalgamation was dropped, and it was decided that, with a view of avoiding the building of another station, the two engineers of the electrical and tramways departments respectively should prepare separate reports as to how the existing station and the power station at Roath could be utilised for supplying additional current for lighting and traction purposes, the date upon which current would be available, and the price thereof.

Amalgamation.—We are informed that an amalgamation has been effected between Messrs. the Maxim Electrical and Engineering Export Company, Limited, 65, 66, and 67, Gracechurch-street, E.C., and Messrs. Edwards and Barnes, engineers, Westminster. The allied firms will trade under the style of the Maxim Electrical and Engineering Export Company, Limited, 65, 66, and 67, Gracechurch-street, E.C. The entire staff of this business is still retained, and Mr. Howard T. Wright remains manager of the department taken over. This company are making a speciality of central electric light and power station steam accessories, including condensers and economising plants.

Price-Lists.—We have received from Messrs. J. Gibbs and Son, of Duke-street, Liverpool, a copy of their latest price list dealing with their patent air propelling and ventilating fans. The diameter of the blades of these fans varies from 15in. up to 72in., and the price from £3 to £41. 10s. Their electrical fans are fitted with an enclosed motor, and in order to meet the demand for small apparatus for ships' cabins, offices, etc., the firm are now producing a fan of small size at a reasonable cost, and capable of being driven at various speeds. We have also received from Messrs. Gibbs and Son a copy of a testimonial recently received from Mr. S. B. Cottrell, M.I.C.E., M.I.M.E. from which we gather that the firm have been successful in reducing the temperature of the Liverpool Overhead Railway Company's generating station by nearly 15deg. F. by means of some of their fans.

Hull.—The council of the Hull Incorporated Chamber of Commerce and Shipping held its monthly meeting on Monday. Referring to the decision of a committee of the City Corporation to apply to the Postmaster-General for a license to establish a municipal telephone system it was asked whether it would be substituted for the old system, or whether it would be an additional one. It would be a serious inconvenience to have two systems in operation. The Chairman understood that the two systems would be joined together, so that subscribers to the Corporation system would have access to the National one. If the two did not interwork no one would support the new one. The council expressed dissatisfaction with the rebate offered by the National Telephone Company with respect to the breakdown last February, and they therefore withheld the payment of the year's account.

South African Contracts.—The *British and South African Export Gazette* contains the following information on South African contracts: "A complete electric power installation for the Rezende gold mine, Rhodesia is in course of shipment. A small generating plant is to be ordered for the electric lighting service of East London, Cape Colony. The installation of an electric lighting service, at an estimated expenditure of from £3 000 to £8.000, is under consideration by the Uitenhage Town Council, Cape Colony. The Cape Government propose to make additions to their telegraph and telephone systems to the extent of £30,018. The details include additional telegraph wire, £9,105; automatic fast-speed apparatus, £3,150; extensions of telephone systems, £15,263; additional switchboards for Cape Town and Port Elizabeth,

Digitized by Google

£2,000. The Durban Corporation are about to place an order for two additional engines for the electric lighting service.

Dudley.—The Mayor (Mr. E. Grainger) and the chairman of the Electric Lighting Committee on Monday initiated the lighting of the principal streets of the town. Mrs. Dunn switched on the current The sum of £33,000 has been borrowed to carry out the scheme, and an additional £10,000 is to be obtained for free wiring houses and business premises for electric lighting purposes. In connection with private consumption the cost will be 6d. per unit (equivalent to 9d. per 1,000ft. for gas) for two hours per day, and 1½d. per unit for the remaining 22, which is stated to be the lowest price charged by any municipality in England. It is estimated that the electric lighting in Dudley will consume 270,000 units a year. The newly-erected power station at Springsmire is not quite completed, but current has been supplied to the tramways to Cradley Heath and Sedgley during the last fortnight.

Islington.—At the last meeting of the Vestry, the treasurer gave some interesting figures relating to the cost of the electric light undertaking. He said the ratable value of the electric lighting property was at the present time £3,094, but at the last quinquennial valuation the amount was raised to £3 790. The amount of outstanding loans on the undertaking was £325,863. For the past six months ending June 30 there was a profit in the working of the undertaking of £5,087. 14s. 10d. A sum of £1,523. 5s. 3d. had to be set aside for redemption of debt, a sum of £4,158. 15s. 7d. for paying interest on loans, and a sum of £64. 8s. 10d. had to be written off for bad debts. The profit on the undertaking was insufficient to meet those charges by £638. 14s. 10d. The ratable value of the parish for the year ending September, 1894 was £1 717 414. At the present time the ratable value was £1,835,193. Mr. H. L. Mills, the electrician-on-mains, has resigned his position.

Wrexham.—The extension to Ruthin-road has been confirmed by the Council. The cost, including cable for the two arc lamps, will be £172. The following epitome has been prepared by Mr. Trentham of the expenses undertaken or recommended by the Town Council up to the 16th inst.—viz.: Messrs. Davies Bros.' contract, £1 122; boiler setting, £143. 13s. 9d.; new girders for water-tanks, £44. 10s; Messrs. Babcock and Wilcox, two water-tube boilers £1,761. 16s. 7d., water softener £250; Mr Lord, Lancashire boiler, £825; Lancashire Dynamo Company, £7 286. 10s.; Messrs. Brook, Hirst, and Co., switchboard, £589; St. Helens Dable Company, £4,499. 11s. 7d., nine extra arc lamps, Egerton-street extension and Ruthin-road extension, £438. 10s.; Chloride Battery Company, £991; Messrs. Carrick and Ritchie, £140 and £16; Messrs. Meldrum, destructor, £1 630; and consumers' connections and meters arranged for, £500—making a total of £20 240. 11s. 11d. To this has to be added engineering fees and presumably tipping platform for destructor.

Sheffield.—The Markets Committee of the Corporation, says the *Sheffield Daily Telegraph*, might very well take a hint from Leeds as to the lighting of the markets by electricity. Mr. S. E Fedden, chief engineer and manager of the Sheffield electric light department, recently visited Leeds and inspected the new installation of arc lighting at the covered market there. Eighty enclosed alternating arc lamps of the "Reason" type have already been installed, and another 40 are on order for extension of the buildings not yet completed. The Markets Committee have put in a large number of lamps, and the light at night is almost equal to daylight. Apparently the question of cost has not so much been considered as the obtaining of a thoroughly good light, and thus facilitating the transaction of business. The charge to the committee is 3½d. per unit for lighting, but this figure will probably be reduced after a time. The results obtained are eminently satisfactory, and there is no doubt that the cost incurred will in the near future be indirectly if not directly recouped.

Presentations.—Mr. John Ferguson Bell, A.M.I.C.E., late engineer and manager of the gas and electricity works of the Stafford Corporation, was presented last week with a testimonial from many friends in the town on his leaving to take the management of the Derby gasworks. The presentation was made in the Mayor's parlour at the borough hall, Mr. C. H. Wright (chairman of the Gas and Electricity Committee) presiding. The testimonial consisted of an illuminated address and a silver tea and coffee service and salver. The inscription upon the latter referred in most eulogistic terms to Mr. Bell's services to the Corporation during the last 17 years. The employés at the gas and electric light works presented Mr. Bell with a very handsome silver tray suitably inscribed.—The staff and employés of the electricity works of the Huddersfield Corporation have presented Mr. J. R. P. Lunn, the mains superintendent, who has left to take the position of borough electrical engineer at Darlington, with a timepiece and ornamental figures which had been subscribed for by the staff and employés.

Personal.—Mr. G. Swift, of the Electric Construction Corporation, Wolverhampton, has been appointed a shift engineer at the Blackburn electricity works in the place of Mr. J. W. A. Binnes, who has been appointed assistant engineer at the Accrington Corporation electricity works.—Mr. Samuel Hartford, of Collier-street, Salford, Manchester, having resigned the secretaryship of Messrs. W. T. Glover and Co., Limited, Salford and Trafford Park, Manchester, has commenced business at that address as agent for the following firms: the British Insulated Wire Company, Limited, Prescot; the Brockie-Pell Arc Lamp, Limited; Mr. Wm. Rickard, Derby; and Messrs. W. N. Brunton and Son, Musselburgh, Scotland.—We are informed that Mr. C. McDermid has been appointed secretary to the Institution of Mining and Metallurgy, of London, and he is consequently leaving the Iron and Steel Institute, where he has for seven or eight years been assistant secretary under Mr. Bennett Brough. We wish Mr. McDermid every success in the new position which he is about to occupy.

Leigh.—Mr. G. W. Wilcocks has held an enquiry into the application by the Town Council to borrow £5,000 for electric lighting extensions. The electricity works were completed in January last. Sanction has been given to a loan of £10,216, but £10,546 has been expended on capital account up to the present time. The number of consumers at present is 67, and the number of private 8 c.p. lamps 3,766. There is no public electric lighting at present. The length of the mains already laid is 2 miles 382 yards, and the £5,000 is for extension of mains amounting to an additional 4 miles 1,444 yards. A canvass of the area through which the new mains are to run has been made, resulting in applications from about 50 consumers for 1,500 8 c.p. lamps, and it is estimated that each lamp will burn in a year 5s. 6d. worth of electricity, bringing in a total revenue of £412. 10s. Sufficient power is now available, the additional cost will only be in the generating of the current, estimated at £70. 0s. 3d. The amount of interest and capital required yearly to repay the loan within 25 years amounts to £323. 3s. 9d. The total cost will thus be £393. 4s., leaving a balance of £19 6s.

New Issue.—The Electrical Power Distribution Company, Limited, are making an issue of 12,980 ordinary shares of £10 each, at a premium of £1 per share, through the Electric and General Investment Company, Limited, 1 and 2, Great Winchester-street, London, E.C. The board of directors consists of Mr. J. S. Raworth, M.I.C.E., chairman; Messrs. Emile Garcke M.I.E.E.; C. Shirreff Hilton; R. Percy Sellon, M.I.E.E; and Wm. L. Madgen, M.I.E.E. (managing director). This company was formed in 1898 with a nominal capital of £20,200, the whole of which has been paid up, for the purpose of securing and working concessions for electrical power distribution. The prospectus gives particulars of Acts, and of provisional orders under the Electric Lighting Acts, promoted or secured by the company, or by associated companies, in which the company holds or controls all the shares; also of electric tramways promoted so far by the British Electric Traction Company, Limited. They refer to Gateshead, Durham (City), Jarrow, Hertford, Barnet, Sutton, Carshalton, Wallington, Weston-super-Mare, Penarth, Lewes, Banbury, Sevenoaks, Sheerness, Staines, Egham, and Chertsey, and Wellingborough.

Wednesbury.—In discussing the electric question the *Midland Counties Express* says: "Whilst, as yet, nothing definite has been decided upon by the Town Council, it is pretty certain that no electrical scheme involving any great outlay will be embarked upon at present. But although no course of action has been resolved upon, there is, we understand, a strong feeling amongst the local municipal rulers in favour of leasing the tramway lines in the borough when they belong to the Corporation to some company, who will be expected to run electric cars, and pay every attention to the comfort and convenience of the travelling public. The electricity question, and how to provide an ample supply for the tradesmen and other inhabitants, and also for public lighting, will be the most difficult to grapple with, and in the absence of their own electrical undertaking, the Corporation contemplate, it is believed, purchasing their electricity in bulk from the company who take over the working of the trams, and be responsible themselves for its distribution throughout the town. Whether such an arrangement is possible or not remains to be seen." The Midland Electric Corporation for Power Distribution, Limited, have just given notice of their intention to open and break up certain streets in the borough, pursuant to the powers contained in their provisional order.

London County Council.—On Tuesday the following notices under Electric Lighting Acts and Orders were agreed to: The County of London and Brush Provincial Electric Lighting Company, under the County of London (Northern Extensions) Order, 1897, of intention to lay power mains along Baldwin's gardens; the Blackheath and Greenwich District Electric Light Company, under the Blackheath and Greenwich District Order, 1897, of intention to lay low-tension mains (*a*) along a portion of London-street, and (*b*) along and across Trafalgar-road; the Westminster Electric Supply Corporation, under the Westminster Order, 1899, of intention to lay mains along both sides of Graham-street; the Vestry of St. Pancras, under the St. Pancras (Middlesex) Order, 1883, of intention to lay mains (*a*) along a portion of King's Cross-road and along Woodsome road, and (*b*) along George-street, Euston buildings, and Tonbridge-street. The following notices under orders granted to local authorities were reported: Whitechapel District Board, under the Whitechapel District Order, 1892, of intention to lay mains along Trinity-square, Little and Great Tower-hill, George street, High street, and Norton Folgate; and Vestry of Hampstead, under the Hampstead Order, 1893, of intention to lay mains along Fortune Green-road, Boundary-road, Adelaide-road, Mill-lane, and Westbere-road.

Salford.—The members of the Electric Light Committee and a few other gentlemen met at the new electric light works last week in Strawberry-road, Pendleton, in response to the invitation of Alderman Shaw, chairman of the Electric Lighting Committee, when the new electric works were formally taken over by the Corporation. The Chairman said when the building was finished there would be working 12 large steam dynamos, which would be equal to 12 000 h.p. The electricity produced by these dynamos would not all be used for lighting, but some of it for traction. The steam-boilers would require 36,000 gallons of water to be generated into steam. There would also be required 480,000 gallons of water for the working of the condensers for condensing the exhaust steam, and to assist the engines. This water they had

Digitized by Google

arranged to take from the Lancashire and Yorkshire Railway Canal. There would be five contracts for the buildings, amounting to about £55,000; 14 contracts for machinery and plant, amounting to about £136,000; and four contracts for cable, tramway equipment, etc., amounting to about £180,000—making a grand total of £371,000. At the Wallness-road station a plant had been working continuously for five years, and with very little expense. The demand for current had been so great that it gave the Electric Light Committee great concern. They thought it would be best for them to make provision for the coming winter and they, therefore, engaged Messrs. Mather and Platt to put a 200-h.p steam dynamo there, and it had started working, so that they thought they should get through the winter all right. There are to be 16 boilers in all, each weighing 32 tons, and tested to a pressure of 250lb., while the working pressure will be 160lb. It is considered that two chimneys, each 200ft. high, will be absolutely necessary, and arrangements are being made whereby one chimney can be shut off and the other used as occasion requires. Alderman Linsley (chairman of the Tramways Committee) said the Tramways Committee and the Electric Light Committee had about the same amount of money to spend, and it was their anxious care to put that money to the best possible use. Since February last eight or nine miles of single track of tramlines had been laid, and they hoped to be able to run the electric cars on April 29 next on some of the lines in Salford, and he thought they would be ready in Cross-lane and in Pendleton by that time.

PROVISIONAL PATENTS, 1900.

OCTOBER 29.

19294. The B.B. improved semi-dry storage battery or accumulator for storing electrical energy. Henry K. P. Barham and Edgar N. Bambury, 60, Fratton-road, Fratton, Portsmouth.

19334. Improvements in automatic switches. William Edward Wilson, Daramona House, Streete, co. Westmeath.

OCTOBER 30.

19371. Improvements in starting switches for electric motors. Edward Norris, 284, West-parade, Lincoln.

19338. Improvements in and connected with electric arc lamps. Frederick Richard Boardman, 10, Union-court, Old Broad-street, London.

19386. Improvements in automatic time switches. Charles Herbert Offord and Samuel Jevons, 77, Colmore-row, Birmingham.

19393. Improvements in apparatus for electrically treating air gases and gaseous mixtures. Reginald John Yarnold, 321, High Holborn, London.

19394. Improvements in lampholder switches for electric lighting. George Henry Chard, 5, Budge-row, London. (Complete specification.)

19395. An anti vibration base-frame for motors, dynamos, and other machinery. George Middleton, 8, Quality-court, Chancery-lane, London.

19416. Improvements relating to telephone call recorders. Harold Dudley Stroud, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

19438. Improvements in electric arc lamps. Carl Schuster, 18, Buckingham-street, Strand, London. (Complete specification.)

19444. Improvements in arc lamps. George Croydon Marks, 18, Southampton-buildings, Chancery-lane, London. (Continentale Jandus Electricitäts A.-G. Societe Anonyme, Belgium.)

19448. A new or improved method of controlling the action of electromotors. Charles Ashley Carus-Wilson, Norfolk House, Norfolk-street, Strand, London.

19449. A new or improved method of controlling the action of electromotors. Charles Ashley Carus-Wilson, Norfolk House, Norfolk-street, Strand, London.

19451. Improvements in and relating to electrical condensers George Frederick Mansbridge, 322, High Holborn, London.

OCTOBER 31.

19470. Improvements in electric switches. Crompton and Co., Limited, and Sydney Linton Brunton, Arc Works, Chelmsford.

19471. Improvements in electrical switches. Crompton and Co., Limited, and Henry William Wartnaby Dix, Arc Works, Chelmsford.

19482. Improvements in electric ignition for internal-combustion motors. William John Crossley and Cyril Joseph Atkinson, Openshaw, Manchester.

19486. Improvements in electric clocks. Frederick William Leake, Liverpool-street Station, London.

19494. Improvements in slot wedges for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Henry G. Reist, United States.) (Complete specification.)

19495. Improvements in systems of electrical distribution. The British Thomson Houston Company, Limited, 83, Cannon-street, London. (William Le R. Emmet, United States.) (Complete specification.)

19496. Improvements in induction electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

19497. Improvements in automatic circuit breakers for electric circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett, United States.) (Complete specification.)

19498. Improvements in circuit breakers for electric currents. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett, United States.) (Complete specification.)

19499. Improvements in systems for controlling electric motors and electrically-propelled railway trains. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Frank E. Case, United States.) (Complete specification.)

19500. Improvements in electric switches. The British Thomson Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett, United States.) (Complete specification.)

19506. Improvements in electric arc lamps. Frederick James Green, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

19509. Improvements in the manufacture and production of solid ends on wire ropes, electrical conductors, and the like. Thomas Joseph McTighe, 47, Lincoln's-inn-fields, London.

19511. Improvements in dynamo-electric and electro-dynamic machines. John Herbert St. Hill Mawdsley, Norfolk House, Norfolk-street, Strand, London.

19512. Improvements relating to electric circuit breakers or switches. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (McElroy-Grunow Electric Railway System, United States.) (Complete specification).

19516. An improved device for regulating engines for driving electrical dynamos and the like. Johann Rudolf Frikart, 6, Lord-street, Liverpool.

NOVEMBER 1.

19539. Improvements in trolley poles and standards. Arthur James Ireland and Charles William Godson Little, 10, Mortlake-road, Kew, Surrey.

19554. Improvements in and relating to combined telephone and sound telegraph apparatus. Carl Ernest Ljungman, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

19570. Improvements in or relating to overhead trolley wires or conductors for electric traction, overhead electric cables, or the like. Augustus Wyvill Hancock, John Leighton, and Robert Hacking, 111, Hatton-garden, London.

19576. Improvements in electric switches and in ships' telegraphs, railway signalling apparatus, and the like. Adrien Louis Augustin Charles d'Arlincourt, 53, Chancery-lane, London.

19588. Improvements in automatic electrical switches and circuit breakers. Joseph Booker and Piers Sumner, 70, Chancery-lane, London.

19594. Improvements in alternating-current transformers or economy coils. John Llewellyn Davies, 40, Chancery-lane, London.

19595. Improvements in or connected with arc lamps. John Llewellyn Davies, 40, Chancery-lane, London.

19612. Improvements in or relating to the renovating of electric incandescent lamps. Alfred Julius Boult, 111, Hatton-garden, London. (La Saymar Omnium Industriel d'Electricité Societe Anonyme, France.)

NOVEMBER 2.

19616. Improvements in electric railway car or vehicle trolleys. George Prescott, 15, Water-street, Liverpool.

19623. An improved gastight fuse and junction box for electric cables. Percy Joseph Emmerson Kennedy and Harold Cornelius Reading, Bretby, Burton-on-Trent.

19658. A new and improved process of insulation of electric wires or cables. Max Hankin, 15, Copthall-avenue, London.

19672. Improvements in wireless telegraphy and in apparatus therefor. Eugène Pilsoudsky, 6, Lord-street, Liverpool.

19674. Improvements relating to electric railways working on the surface-contact system. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William Milton Brown, United States.) (Complete specification.)

19686. Improvements in accumulators. Georges de Roussy de Sales and François Gueugnon, 24, Southampton-buildings, Chancery lane, London. (Complete specification.)

NOVEMBER 3.

19736. Improvements in de-cohering apparatus for wireless telegraphy. Jonathan Zenneck and the Prof. Braun's Telegraphie Gesellschaft mit beschränkter Haftung, 55, Chancery-lane, London.

19737. Improvements in signalling by means of electric waves. Jonathan Zenneck and the Prof. Braun's Telegraphie Gesellschaft mit beschränkter Haftung, 55, Chancery-lane, London.

Digitized by Google

19754. Improvements in and relating to key sockets for incandescent electric lamps. Owen David Lucas, Thomas Herbert Marsh, and Albert Vandam, 322, High Holborn, London. (Complete specification.)

19759. Improvements in electric traction systems. William Aitken, Pine Glen, Muswell-avenue, Muswell-hill, London.

19765. Improvements in electric resistances. Walter Pitt, 24, Southampton-buildings, Chancery-lane, London.

19766. Improvements connected with overhead trolley poles used in electrical traction. William Ellison Rowlands, 10, St. George's-crescent, Liverpool.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Nov. 24.

1899.

21844. Portable telephonic apparatus. Holden.

22163. Continuous current electricity meters. Schattner.

24524. Electric accumulators. Leve and Monobloc Accumulator Syndicate, Limited.

24805. Appliances for reversing the current in continuous-current dynamos. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellshaft.)

25053 Connectors for electrical wires or cables. Sowerbutts.

25353. Liquid resistances for electrical circuits. Moy, Bastie, and Ernest F. Moy, Limited.

25628. Electric fishing apparatus. Lindbohm.

1900.

81. Electrically-operated clip to be employed in machines for tentering and stretching fabrics Whiteley and Whiteley, jun.

163. Automatic make and break for electric circuits. McFarlane and Reid.

216. Manufacture of active mass for accumulator batteries. Rodrian.

3158. Fluid pressure thermo-dynamic engines. Wainwright.

5764. Means for retaining the field-magnet coils of electric motors and dynamos in position. Lindstrom. (Date applied for under International Convention, Oct. 16, 1899.)

13048. Means for controlling the speed of electromotors. Elliott and Eskholme.

14458. Telegraphic relays. Wilson.

14582. Electric furnaces. Chavarria-Contardo.

15298. Wireless telegraphy. Wilson.

16129. Dynamo-electric machines. British Thomson-Houston Company, Limited. (Steinmetz.)

16130. High-potential electric switches. British Thomson-Houston Company, Limited. (Hewlett and Emmet.)

16147. Electrically-propelled motor road vehicles. Ryan.

16483. Portable electric batteries. Fuld.

17549. Electrically operating signal bells and apparatus for that purpose. Jerrard.

NOTES.

Personal.—We are informed that the council of the Tramways and Light Railways Association have appointed Mr. Norman Thompson, B.A. (Cantab), A.I.E.E., as secretary of the association, his offices being at Clun House, Surrey-street, W.C.

A New Appointment.—The Postmaster-General has, we learn, appointed Mr. Thomas Mason, the chief superintendent of the special telegraph arrangements branch, to be traffic manager for telegraph business in the United Kingdom. This is a new departmental post, and we hope that Mr. T. Mason will have every success in the first occupancy of it.

Institution of Electrical Engineers.—We are informed by the secretary that an extra meeting of the Institution will be held, by kind permission, in the rooms of the Institution of Mechanical Engineers, at 8 p.m., on Thursday, Nov. 29, when a paper will be read by Mr. W. E. Langdon, vice-president, on "The Supersession of the Steam by the Electric Locomotive."

The Harness Case.—There is an echo in the daily Press this week of a case which interested electrical engineers very much a few years ago. We refer to the bankruptcy examination of Mr. C. B. B. Harness, who was so prominently connected with the Harness electric belts. His present condition is stated to be—assets, nil; liabilities, £7,500. It was stated in the course of the examination that from 1890 to 1892 over £15,000 profit was made out of the electric belts.

Obituary Notice.—We sincerely regret to have to announce the death, on the 7th inst., of Herr Johannes Hausmann, who for close upon 25 years has acted in the capacity of chief engineer to the world-famed firm, Felten and Guilleaume, Carlswerk, Mulheim-am-Rhein, Herr Hausmann seems to have won the high esteem of his employers, not only on account of the distinguished abilities which he displayed in assisting to build up a magnificent business, but also in virtue of his splendid social qualities.

The Paris Medals.—The Parisians do not appear to have had a very great amount of success with their exhibition, and in awarding the medals and prizes things have, it would seem, become a trifle mixed. Large numbers of gold and silver medals were to have been awarded, but the expense appears to have frightened the French Government, who have now decided that only bronze medals can be given. It is very considerate, however, and kindly offers if gold and silver medallists care to take their bronze medals to the Mint and to pay for having facsimiles struck in the more precious metals, to do the minting work for them.

Acetylene Gas.—Dr. Frederick Rose, the British Consul at Stüttgart, reporting on the trade, etc., of Wurtemberg in 1899-1900, refers to the rise and progress of the acetylene gas industry. It is at present impossible to predict, he asserts, the ultimate result of the struggle between this new illuminant and its rivals. The probability is, he adds, that petroleum will suffer most, that coal-gas will be superseded to a great extent, especially with regard to the lighting of small towns. Electricity, however, will not, he thinks, be appreciably affected, and this opinion will probably be gratefully received by the holders of electric shares.

High Voltage Through Cables.—We understand that some successful experiments have been made at St. Paul, U.S.A., on underground cables using 30,200 volts. In this case a triple-core cable was employed, with paper insulation and lead sheathing. The cable in question was drawn into stoneware ducts about three miles in length. Up to the present satisfactory results have been obtained, and the cable is to be used in connection with a system of distribution of power. Besides the underground portion of the cable, 24 more miles of overhead wire will be required in order to reach the Apple River, where the power station is situated.

Incandescent Lamps for High Voltages.—While the 220-volt lamp is now the standard article in England, it has not found favour to such an extent abroad. In the States, for instance, they still talk about the unsatisfactory performance of the 16-c.p. 220-volt lamp, and of the worse troubles which arise from the use of smaller candle-power lamps at that voltage. Our success in this is due to the competition between the very numerous lampmakers in this country. Of course, the higher-voltage lamps are not yet quite so efficient as those made for 100 volts, but it is very much better than was the case two years ago. As a consequence, English engineers are able to obtain much more income from the same size network than their American contemporaries.

Elberfeld.—Good reports of the 1,000-kw. steam turbo-generator constructed by Messrs. Parsons and Co., Newcastle-on-Tyne, for the new electricity works in Elberfeld, Germany, are to hand. The set was run in position for the first time on the 9th ult., and on the 13th was paralleled with the 1,000-kw. triple-expansion steam alternator comprised in the other plant installed, subsequently taking over the whole of the Sunday night alternating-current load, which represented a maximum output of 550 kw. The paralleling of the turbo-generator running at 1,500 revolutions per minute with the triple-expansion set running at 93¾ revolutions per minute, which speeds correspond to the full periodicity of 50, was accomplished, we understand, without the slightest difficulty. We trust this success will influence further orders for British-made generating plant in the same direction.

Unauthorised Supply.—What seems to us to be a hard case was recently tried at the Barnsley Borough Court. An electrical engineer was charged with supplying his next-door neighbour without having obtained the permission of the Corporation to do so. The next-door neighbour had applied to the Corporation for a supply, and there was evidence brought of the fact that the electrical engineer connected his neighbour's wiring on to his own meter for his neighbour's convenience until the Corporation had completed their connections. That no fraud was intended is doubly assured, in that the electrical engineer would have the electricity registered on his own meter, the other proof being that he told an assistant engineer of the Corporation that he had made the connection. After hearing the case, the magistrates inflicted a fine of £1 and costs. While we quite believe in upholding by-laws and regulations, we think from the report that we have seen of the case that this prosecution was absolutely unwarranted, as in cases of emergency all rules may have to be broken.

The Liverpool Self-Propelled Traffic Association.—The opening meeting of the session of this local section of the Automobile Club of Great Britain and Ireland is to be held on Dec. 3 at the Royal Institution, Colquitt-street, Liverpool, when an address will be delivered by Mr. M. G. Forestier on "Heavy Motor Traffic in France." The lecture should be a very interesting one, as Mr. Forestier, in addition to his office as engineer-in-chief to the Department of Roads and Bridges under the French Government, is president of the technical commission which conducted the heavy motor trials at the recent

Digitized by Google

International Exhibition at Paris, and of the commission of organisation for various trials arranged by the Automobile Club of France. He was also president of the International Congress on Automobilism held in Paris last July. The cinematograph has been pressed into the service of the lecturer, and those who attend the meeting should receive a good impression as to the extent to which traffic with heavy motor vehicles has advanced in France. A luncheon is also to be given to the club by the Lord Mayor of Liverpool (Councillor Crosthwaite) at the town hall, on the day following the opening meeting—viz, Dec. 4.

The Capital Value of Waterfalls.—The continent of North America is wonderfully favoured in respect to the water power which it has available in connection with what is the largest system of fresh-water lakes and rivers in the world. As our contemporary, the *Electrical Review* of New York, justly points out in an editorial article, the value of large waterways has been realised from the first settlement in the country, and the connections between the great chain of inland seas and the ocean has been greatly improved. A new phase of the value of this large water system is now beginning to be developed, and our contemporary points out that no less than 400,000 h.p. of plant is being laid down at the present time or is in actual work. Still, this horse-power represents but a very small percentage of what could be obtained, but the capital cost of the same is by no means insignificant. Our contemporary estimates the income from the above-mentioned horse-power at £1,600,000 per annum. The capital value of an income of this kind is, of course, very much larger, but our contemporary is quite wrong in putting it so high as 500 millions sterling, as at this figure the income is not 1 per cent. However, even with another cipher struck off the capital sum, one cannot but realise what a large value the waterfalls are to the country in which they are situated.

Institution of Electrical Engineers.—We have received from Mr. E. W. Cowan a copy of the programme of the Manchester section of the Institution of Electrical Engineers. In this section of the Institution the meetings are held fortnightly, on Tuesday evenings at 7.30 p m. The first meeting took place last Wednesday, Nov. 13, Dr. E Hopkinson being in the chair, when Prof. A. Schuster, F.R.S., read a paper on "Some Phenomena of Electric Sparks." Other papers to be read are on "Relative Advantages of Direct-Current and Three-Phase Distribution for Small Installations," by Mr. Hardman A. Earle; "The Proposed Manchester and Liverpool Express Railway," by Mr. F. B. Behr; "Direct-Current Generators," by Mr. L. H. Short; "The Training of Electrical Engineers," by Dr. John T. Nicolson; "The Use of Storage Batteries in Connection with Electric Tramways," by Mr. G. A. Grindle; and "The Adaptation of the Steam-Engine to the Generation of Electricity," by Mr. J. S. Raworth. There are yet two or three dates for which papers have not yet apparently been sent in, but it is probable that once the section gets properly to work there will be no lack of offers for papers to supply these vacant dates. The hon. secretary of this section of the Institution is Mr. E. W. Cowan, Springfield-lane, Salford, Manchester.

The American Street Railway Convention.—The November number of the *Street Railway Journal* contains a very long notice of the American Street Railway Convention, recently held at Kansas City. The list of exhibits, which is given by our contemporary, is very full, and one notices a good many exhibits which are of general interest. For instance, the Wheel Truing Brake-Shoe Company, of Detroit, Michigan, exhibited a special form of brake-shoe, which consisted of an iron frame in the form of a brake-shoe, but which was filled with an abrasive material, probably emery, which is intended to be put on in place of the ordinary iron brake in cases where a flat wheel occurs. The special shoe is kept in service until the flat place has been worn off. An extensive use is claimed for the shoe in the United States, it being stated that the factory is now working night and day in order to fill orders. Another device was that shown by the Garton-Daniells Company, of Keokuk, and called the "automotoneer." This arrangement is intended to be applied to the controllers on street cars in order to prevent the motorman from starting off too suddenly or from throwing the handle too far on an emergency stop, which usually has destructive effects. The device in question enforces a pause on each notch of a controller, and can be adjusted to allow the car to be started in seven, ten, or twelve seconds.

The Mansion House Subways.—We have received from Mr. David Ross, the engineer to the Corporation of London, a copy of a report prepared by him as to the number of persons using the subways beneath the open space in front of the Mansion House. The first observation, taken on March 12 last, when the subways were partially completed, showed that the number of persons entering the subway was 25,637, of which some 6,400 booked from the Bank to Waterloo by the Waterloo and City Railway, leaving a total of 19,237 persons who used the subways without the railway. On April 25 the number, exclusive of railway passengers, was 15,276. The whole of the subways were opened on July 30, when the Central London Railway was opened to the public, and on Aug. 15 the returns showed a total number of persons using the subways, exclusive of railway passengers, of 19,600. On Oct. 3 the observations taken showed a decrease on this figure, the number being only 16,011. The observations were made over a period of 20 hours, from 5 a.m. to 1 a.m. The engineer therefore thinks that the number of persons making use of the subways with the object of avoiding danger and difficulty in crossing the open space in front of the Mansion House is but small compared with the enormous number of pedestrians passing over the surface at this spot. It is difficult to ascertain the exact number of these, but it is estimated from recent observations to be between 180,000 and 200,000 in the 20 hours from 5 a.m. to 1 a.m.

The Faradian Club.—The first smoking concert in connection with the Faradian Club was held at St. James's Restaurant last Friday evening, when Mr. Robt. Hammond filled the office of chairman. Before giving the word to proceed with the concert, Mr. Hammond said it gave him great pleasure to preside at this first smoker of the club, although it was not the first thing which the club had done, as they had previously had a club dinner. He was pleased to preside because the club was connected with an institution with the founding of which he had to do. He was glad to see in the room some of the old members of the Hammond College, out of which had sprung the Electrical Standardising Institution. It delighted him to think that if the old Hammond College was a bit too soon in the electrical world, it had been worthily succeeded by the Electrical Standardising Institution, and he was glad to know that there was such a bond between the members of the institution as had brought them there that evening. Although Prof. Perry had told them the previous evening that they should be purely mathematical and theoretical to the core, there were certain events, of which this was one, which did not come under these heads. He then mentioned that it was the Prince of Wales's birthday, and asked Mr. G. W. Lloyds, the pianist, to open the

Digitized by Google

concert with something appropriate to that day. The concert then commenced with a pianoforte solo, "God Bless the Prince of Wales.' The songs on the whole were humorous, Messrs. Will Edwards, H. W. Berry, R. Ganthony, and H. Harvey shining particularly. Mr. W. Murray Bemister sang some very striking songs, particularly an Hungarian folk song, in which a shepherd intimated his intention of hurting a prospective bridegroom with a bludgeon. Banjo duets and coon songs were well rendered by Messrs. Montagu and Robson, Mr. Montagu also giving a solo on the mandoline.

The Electrolytic Production of Soda and Chlorine.—Mr. Jas. F. Hobart has been contributing a useful series of articles on the above subject to the *American Electrician*. In the earlier issues he has dealt generally with the apparatus, giving most useful information, but in the last article, which appears in the November number, he deals with the general arrangement of a number of cells such as are used in commercial work. The arrangements he describes were got out for the Mercer cells when the experimental plant for the same was being laid down as a guide for larger practice. In this case the earthenware porous pots were about 18in. in diameter, the total height of the cells being about 3ft. These pots form the diaphragm of a double-fluid cell for the production of chlorine and caustic soda. Round the outside of the porous pots a layer of asbestos paper were wrapped, on to which a perforated iron strip about 12in. wide was secured by iron clamping bands. This formed the negative element. The porous pot with its iron sheath was then placed in an iron tank which was built to contain five cells. The positive plate was of carbon. Illustrations are given of the cells to show how the chlorine was collected. One of the most interesting features about the arrangement is that by which the liquid was kept circulated and the cells kept full by placing 20 of them in a line, each one a fraction of an inch below the one preceding. An outlet for the liquid was then provided through what is known as a drip pipe. It was necessary that the water should drip, as otherwise a stream would provide a path for current between one cell and the next. Both the solutions were circulated in this way. For instance, in the alkali side pure water was poured into the first tank, it coming out practically strong caustic alkali at the other end of the series. The author also gives some interesting details as to the reservoir for chlorine gas, which was led out from the cell into an earthenware pipe and thence to the reservoir, where it was mixed with water. The following figures were obtained with this plant in January last on a 23 hours' trial: the average ampere-hours were 138, the available chlorine liberated being 563lb., and the available caustic soda liberated 630lb.

Shipbuilding.—We have received a proof of the presidential address by Mr. H. Withy to the North-East Coast Institution of Engineers and Shipbuilders. The remarks naturally refer almost entirely to shipbuilding and its allied trades. To show the advance made in shipbuilding the president instanced the cases of the "Phœnix" paddle steamer, which in 1819 went across the Atlantic in 29 days 11 hours, and the "Deutschland," which recently crossed in 5 days 11 hours. The use of pneumatic tools for riveting, drilling, caulking, etc., is then mentioned, there being, it was stated, a great field open for the substitution of machine riveting in the place of hand labour, which was more difficult as the size of the vessels increased. The number of vessels of a large size built in Britain for foreigners was commented on, the Continental supply not appearing to be nearly equal to the demand. As to the use of electricity, he thought a plant of multitubular boilers, with triple-expansion engines coupled direct or connected by belts to dynamos, left very little to be desired, either in economy or upkeep. At Middleton Shipyard they had for over five years employed a plant of this description, and during 1896-7 the cost of power production, attendance, and repairs was 6·4d. per pound of wages paid; or, to take another figure, the cost of power production worked out at ·9d. per Board of Trade unit. Since introducing electric driving the wages bill had been doubled, and also the number of machines, but the cost of superintendence had not relatively increased, and it was considered that electric driving was a large factor in the increased output. Middleton Yard was the first in the world to be wholly worked by electricity. Great strides were being made in America with large electric cranes for dealing with coal, ores, etc., and before long an electric crane would be at work in a shipyard on the Tyne with a fore and aft travel of 950ft., and an outreach from the centre on each side of about 100ft., and a lift of 80ft. Great improvements had been made in the manufacture of tools during the last few years, and although there were a large number of American tools of a high efficiency in this country, he believed it possible to get machines of equal or better design and quality made in England. He thought our manufacturers would do well to specialise as the Americans had done.

Polyphase Motors. — In *Cassier's Magazine* for November there is an interesting article on "Polyphase Motors for Driving Tramcars," from which we take the following abstract. The author points out that one of the characteristics favourable to the use of polyphase tramway motors is their action in holding back, by returning energy to the feeders, when they are driven above speed by a car running down hill. This action is entirely different from any that may be simply gained in series-wound continuous-current motors, but is analogous to the performance which would be shown by shunt-wound motors under similar conditions if they could be satisfactorily adapted to the requirements of electric traction. The action is very simple, and is a safeguard which cannot be over-estimated for cars operated over heavy grades. Suppose, for instance, that a car approaches a dip in grade with the motors working. Upon entering the grade it is natural for the speed of the car to increase, which, with continuous-current series-wound motors, will continue until the speed quickly becomes dangerous unless the motors are cut off and the brakes applied. A failure in brakes under these conditions has often resulted in frightful accidents. With induction motors, however, as the car increases in speed the forward rotary effort of the motors decreases, and gradually and smoothly changes into a retarding effort, while the power given up by the car as it runs down hill is automatically returned by the motors to the line. Thus the power of the descending car is automatically placed where it may be usefully applied in operating other cars, instead of being lost in wasteful and injurious friction between brake shoes and wheels. All this is done by inherent action in the motors themselves, and is entirely independent of the motorman. Stops may be made on a grade in the usual manner by cutting off the motors and applying the brakes, and starting is accomplished by the ordinary process, after which the motors may again be left to care for themselves. It is also interesting to note that polyphase alternating-current railway plant, properly installed, removes much of the difficulty from electrolysis of water-pipes and other underground metallic structures, notwithstanding the use of the rails for one branch of the circuit; but, on the other hand, in the line construction are involved all the difficulties of the double trolley.

The Automobile Club.—In the trials which took place last week in connection with the Automobile Club, in the trial over 30 miles of hilly road the Electrical Vehicles Company's "Powerful" completed 28 out of the 30 miles and then withdrew owing to accident caused by shying horse. The National Motor Syndicate's "Joel" car covered 26½ miles, but was delayed by chain coming off; the Electrical Motive Power Company's car, the Canadian Electric Motor Company's car, and the Electrical Undertakings' car each completed 22 miles, the Canadian car having four passengers and the other cars two passengers, including driver. The "Columbia Stanhope," the Delivery car, and "Tourjours Contente" were withdrawn from trials on Wednesday. The concluding run on Friday last took place over a fairly level course, the object being to show how far the vehicles could go on one charge. Unfortunately, owing to the heavy rain on Thursday night, the roads were deep in thick and greasy mud, this considerably retarding the progress of the machines. The British and Foreign Electrical Vehicle Company's "Powerful" carriage, however, completed 65 miles. The Canadian Electric Motor Company's car had to abandon the run at the end of 23 miles owing to an accident to a ball bearing, the Electric Motive Power Company's car being also withdrawn at the end of 15 miles. The "Joel" car was withdrawn at the end of three miles owing to punctures, but the Electrical Undertakings' carriage completed 38½ miles. In view of the fourth anniversary of the Locomotives on Highways Act of 1896, the Automobile Club held their annual run on Nov. 10 to 12, the destination being Southsea. The number of vehicles entered for the run was 149, some 110 cars actually starting on Saturday morning. The programme issued by the club for the run bound down all drivers not to run at a greater speed than 12 miles per hour on clear country roads and eight miles per hour in towns and villages. Diplomas for completing the journey from London to Godalming, and from Godalming to Portsdown, without a stop, and at a speed not greater than 12 miles an hour, were offered. At Portsmouth the Mayor reviewed the cars, a dinner being given in the evening, at which some 200 owners and drivers of motorcars were present, the Hon. J. Scott Montagu, M.P., being in the chair. A silver cup, value £5, was offered for the cleanest vehicle on its arrival at Southsea Common, and was won by Mr. H. Edmunds, to whom it was presented by the Mayor of Portsmouth.

A Self-Driving Weight Motor. — It will be remembered that some months ago we published a description of what Mr. A. E. Gilbert considered to be a perpetual motion machine, or, even more than that, a machine by which power could be obtained from gravity. Mr. Gilbert now forwards us the following note, which we insert in order that we may at the same time point out to our readers the absurdity of the claims made by the inventor. There is in this country no objection to any man patenting the most absurd device he can think of. In the same way there is nothing to prevent him offering this device to her Majesty's Government through Lord Salisbury, but we do think there are grave objections to Mr. Gilbert or any other inventor asking for financial assistance in connection with a scheme which is based on the assumption that the well-known laws of the conservation of energy have been successfully broken. We are sorry that Mr. Gilbert has, after our repeated warnings, wasted his own money on a patent for a form of gravity motor. This money would have been much more profitably spent in class fees for a theoretical mechanics' course at one of the many technical schools with which Newcastle-on-Tyne is blessed. We sincerely hope that he will not get anyone else's money to waste in such absurd schemes. The following is the note as received by us under the above heading: "Mr. Arthur E. Gilbert, A.I.E.E, tells us that he has patented another machine to work on an entirely different principle from those already illustrated in this journal, and that it is one of the grandest and most valuable inventions fathomed during the Queen's reign, on account of his discovering a method whereby the driving power will be quite as great on the ascending side as on the descending side of the wheel. Mr. Gilbert also states that he has made an offer to H.M. Government, through Lord Salisbury, to drive and illuminate all the machinery in Woolwich Arsenal by electricity from one year's end to another without using an ounce of fuel. We are debarred from giving further particulars just yet, as the patents are incomplete in other countries. We, however, wish Mr. Gilbert all success, and that he will soon find the financial assistance he is in search of to complete a model of his wonderful machine. Readers interested in this invention would do well to communicate with Mr. Gilbert direct at 23, King John-terrace, Heaton, Newcastle-on-Tyne." We regret that we cannot endorse the good wishes Mr. Gilbert expresses towards himself in our name.

Increasing Power Factor.—We notice in the *American Electrician* a most interesting description of a three-phase plant used by the Pelzer Manufacturing Company, of Pelzer, Columbia, for their various cotton mills, in which some 120,000 spindles are at work. The water power to drive the electric motors in these four mills is obtained from a point 2½ miles away, where a dam has been built across the Saluda River, giving a fall of 39ft. At present three turbines have been erected, each of 1,200 h.p., which drive directly three 750-kw. alternators, the voltage being 3,600 volts. The equipment of plant in the various mills is largely determined by the fact that certain of them had already a good steam plant available before the water-power station was built. In consequence of this, in mill No. 3 a large synchronous motor only is installed, which will either drive the whole of the load of the mills or will assist the engine when required. Mill No. 4 is entirely driven by motors, which are employed to drive long lengths of shafting for the looms. The motors, which are of the induction type, are of fairly large size. One of the most interesting points in the installation is the use of an over-excited motor of 400 kw. capacity to increase the power factor of the plant. This so-called condenser motor is connected in parallel to the secondary 220-volt mains, so that by its use the watt less currents in transformer line and generators are greatly reduced, thus giving a lower temperature in the transformers and the generator, and less inductive drop in the line. The reduction in inductive drop allowed the generator E.M.F. to be reduced 90 volts with the same impressed E.M.F. at the motor terminals as formerly. The reduction of the current output varied from 8 to 11 per cent. This condenser motor is self-starting from rest, and after once being started and adjusted needs no attention. Repeated tests have shown that this condenser has no effect on the turbine gate opening—that is, the amount of power it saves by the reduction of heat losses in the transformer line and generators, and in the diminished exciting power required for the generator, practically balances the power required for the operation of the condenser motor itself. The exciter of the condenser motor is on the same shaft, so that the machine is a very simple one and works very satisfactorily. Its capacity as a condenser can be quickly varied to suit the character of the load. When the synchronous motor at mill No. 3 is running alone there is absolutely no need for the condenser motor. The power

Digitized by Google

factor of this plant with the full load on without the condenser motor is 86 per cent., and with the condenser it is 94 per cent. Readings are given to show the effect of the condenser motor, the generator E.M.F. without the condenser being 3,780 and the current output 435. With the condenser the E.M.F. was 3,690, and the current output 402. The E.M.F. at the motor terminals was in this test kept constant.

Black Electricians.—From an article in the *Electrical World* we gather that an effort is being made at the Normal and Industrial Institute at Tuskegee, Alabama, to educate the negro and to fit him for occupations rather higher than the ordinary labourer. For this purpose no less than 26 trades are taught in the institute, amongst them being electrical engineering, the course in which is at present being taken by about a dozen students. During recent years some very interesting work has been done by these students under the direction of Prof. Arthur U. Craig, who is himself a man of colour. The electrical department of the institute was started by Prof. Craig in 1895, up to which time only oil lighting had been used in the buildings and extensive grounds. Prof. Craig, however, set to work and designed the building for the central station, and the electrical machinery was given by several of the large manufacturing companies. The plant first installed consisted of one 50-kw. 60-cycle machine of the G.E. type, connected with an exciter, and driven by a Westinghouse engine. The switchboard was of the G.E. type, equipped with a full complement of instruments, also of the G.E. make. This plant was amply sufficient for the first few years, but the growth of the institute has now necessitated the planning of a larger central station. This is now under way, the work throughout—designing and building—being the work of the students of the institute. For the whole of this electrical department no outside help has been used—the installation of the plant, the construction of a pole line in the grounds, the wiring of buildings, etc., being all done by the students. A church which was built by the students some two years ago, having a seating capacity for nearly 3,000 persons, has been fitted with a fine system of steam heating and an artistic installation of electric lighting. In view of the growing demand for current, and the new generating station being well under way, the students in the electrical department are now at work building a large dynamo with capacity sufficient to light the entire institute and grounds. This machine is to be of the multipolar type, and the castings for it have been made in their own foundry from models made in the pattern shop. It is, our contemporary thinks, within the range of probability that as the small city of Tuskegee, within half a mile of the Industrial Institute, is not yet lighted by electricity, some day in the near future the institute may undertake to build a central station, or else supply the city with current as a business enterprise. Also, since the teaming between the railroad station and the institute is something enormous, and calls for the regular use of a long string of mule teams, an electric railway from the steam railroad track direct to the institute, if not indeed the electrical equipment of the dummy railroad, five miles long, which connects Tuskegee with the main line of the Western Railway of Alabama, may some time in the near future be determined upon.

Technical Education.—We have received a copy of the inaugural address given by Sir Alexander Binnie on the occasion of the opening of the session 1900-1901 at the Central Technical College of the City and Guilds of London Institute. He stated that if his remarks seemed to apply more particularly to engineering education, they should understand that they pointed equally to all departments of scientific work and training. He could not but contrast the advantages which they possessed with the scanty means available for scientific education in his earlier years. This was not, however, altogether a disadvantage, as it taught a young man to rely to a great extent on his own endeavours, although there was also much waste of energy. He wished to impress upon them that he had learnt from past experience that without a natural taste for scientific pursuits, without perseverance and determination ultimately to succeed, no college or school training could lead to success. Many young men in his own profession had wasted many valuable years of their early lives in study by entering it without any natural taste for it, or determination to succeed, and have, at the time when they should have been useful though junior members of a great profession, begun to have second thoughts of other spheres of action, and gradually drifted away after having spent several years endeavouring to fit themselves for a calling to which they were indifferent. The classes were divided into various departments for studying certain branches of science, but he wished to urge upon them the advantage of not confining themselves to any hard-and-fast curriculum, but while paying special attention to the branch in which they were interested, to study other branches of knowledge, although this might entail very hard reading and hard work. It was not a question of the number of marks in the institution, but of their success in life, and in life one could never tell when entering upon active work into what avenues or by-paths of practice circumstances might lead. Many men starting in life with fixed ideas of what they were going to do might in course of time find themselves gradually diverted by opportunities opening out before them into quite different branches of practice. To illustrate this, he mentioned his own case. He stated that though originally educated as a railway engineer, circumstances compelled him to take up the study of hydraulic engineering. Again, he had a call of the Indian Government to embark on an enquiry as to the discovery of coal in India, this requiring considerable local geological knowledge. He then went back to hydraulic work and waterworks construction, and later had to do with drainage schemes for large towns, which had made him study biological chemistry. Recently he had been brought much into contact with the use of electricity for various public purposes, the department of engineering knowledge not existing at the time he was a student. He urged upon them the recommendation to study the history of their profession and of the various discoveries which had been made in the past in their different branches of science. With regard to reading, he advised them to read widely and fully on all subjects, however remotely connected with their scientific studies, making copious notes for future reference. He emphasised the need of honesty and straightforwardness in the performance of all duties brought before them, and without fear or favour of any kind whatever. Punctuality and regularity in carrying out their work was spoken of, and also the need for reasonable exercise and recreation. All work should be done with a clear idea of the end to which the work is to be applied, and not merely in order to earn scholarships, degrees, or other honours. It was a frame of mind which he was sorry to see existed in our universities among students who, when questioned as to their future career, reply that they have not made up their mind, and are waiting until after taking their degree. This habit he called drifting, and strongly deprecated, for without a clear perception of what a man was going to be, and how he was going to attain that end, it was almost impossible for him to educate himself properly in the right direction.

THE SCHUCKERT CONTACT SYSTEM OF ELECTRIC TRACTION.

We have received from the British Schuckert Company a well-illustrated description of a number of the most important systems of working electric traction by street contacts which have been tried in the various parts of the world. The volume is rendered more complete by a description of that special stud system of electric traction which has been introduced and perfected by the Schuckert Company of Nuremburg. It was in 1896 that the firm first laid down a contact system for the electric tramways in Munich, and we do not think we shall offend anyone if we say that this system was not a great success. It, however, enabled the firm to obtain a great deal of experience of the trouble and faults of a service on contact systems, and this experience has resulted in the perfection of the system we are now about to describe. In the middle of last year this new system was introduced into Munich, and since then has given, we are informed, complete satisfaction, as, in spite of adverse conditions, it has worked without breakdown.

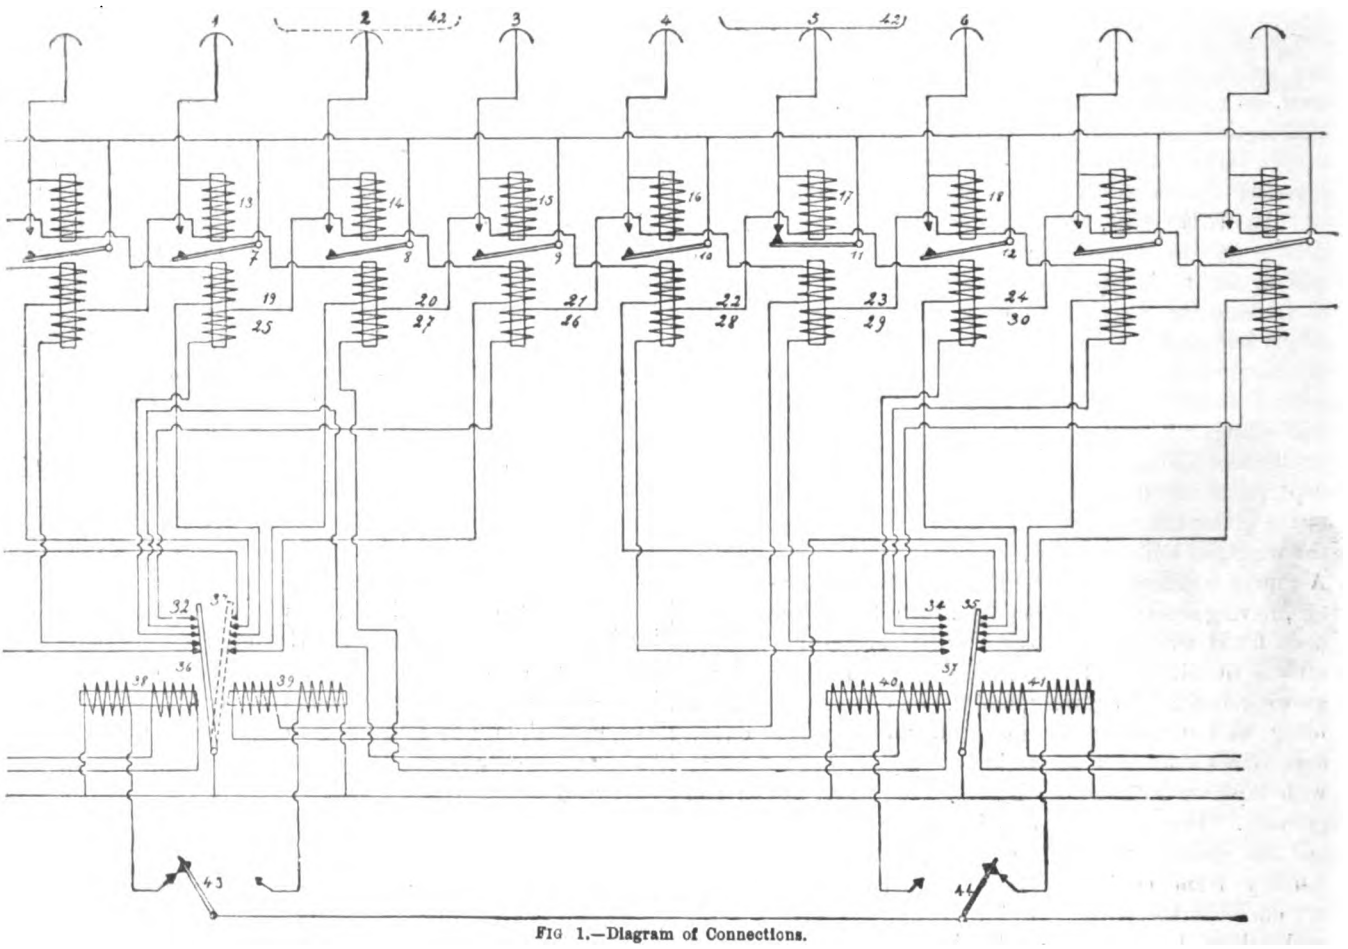

FIG 1.—Diagram of Connections.

The general principle of the system consists in placing the automatic switch gear in groups along the line of route, so that they are easily accessible for inspection. Fig. 1 shows the diagram of connections employed, from which it will be seen that the gear for each stud consists of a contact lever, numbered 7 to 12, which connect the sectional conductor with the main feeder. In connection with each of these levers there are two electromagnets, one of which is used to lift the lever and make connection, whilst the other serves to draw off the lever and break the local circuit. It will be seen that each of the draw-off magnets has two windings on it in order that it may be operated from the adjacent stud in either direction. This is required in order that the cars may run in both directions over the same lines. The coils of the draw-off magnet are connected in groups to contact pieces, which are numbered 32, 33, or 34, 35, which are arranged symmetrically to each other. These are actuated by levers, as shown, by means of other electromagnets, which serve to control the direction in which the car travels. The working of the above system of connections may be briefly described as follows.

Assuming that the current collector, 42, of the car is situated on the contact stud 5, and that the car is required to travel in the direction indicated by the arrow, then the course of the current is as follows: In starting, the current from a small accumulator carried on the car is made use of in the customary way, and passes through the skate, 42, the contact block 5, the magnet coil 17, magnet coil 12, to the corresponding contact of the group 35 through the multiple-switch lever, 37, and thence to the return circuit or to earth. The magnet coil 17 attracts the contact lever 11, and thereby connects the feeder main with the contact stud 5, enabling the car to proceed in the direction indicated by the arrow. The further working of the relays takes place in such a manner that the advance relay in the direction travelled is excited, and closes the circuit immediately its respective contact block is touched by the skate, while the draw-off coil of the surface contact just passed by the collector, but still beneath the car, and which is energised by a shunt current of the advance apparatus, attracts the contact lever and switches the respective section. It should be noted that the multiple-switch levers, 36 and 37, with the travelling direction here assumed, are laid over to the right, touching a series of contacts, 33 and 35 respectively. These levers are reversed automatically and quite independently of the direction travelled as soon as the skate has touched the last of the contact studs belonging to the respective group and connected with the end relay of such group. Assuming that the car is situated with its skate on contact stud 5, and moves to the left in the direction indicated by the arrow, then upon the skate touching stud 4 closing the circuit, the multiple-switch lever, 36, will be reversed, but the current continues to flow through the switch lever, 37, of the rear group, and only commences to flow also through the switch lever 36 when the skate reaches stud 2.

When the car is running in one direction on a double line the reversal of the direction switches is done auto-

Digitized by Google

matically, but if it should be desirable at any time to move cars back in the opposite direction, this can be done by working these switches by hand from boxes placed along the route. In Fig. 2 we give a complete diagram of connections for one car and line, which can be easily understood by following the circuits through. Coming now to the details of the system, Fig. 3 shows a car on the line actually equipped in Goethe-strasse, in Munich, which line

has been working since the summer of last year. One of the section switches and maximum cut-outs used on this line can be seen in Fig. 4. It will be noticed that the box does not occupy much space, and that it is

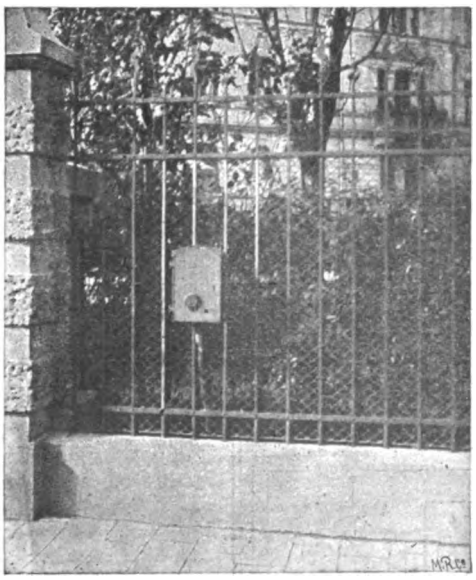

FIG. .—Automatic Cut-Out in Goethestrasse, Munich.

very conveniently placed for access. In Fig. 5 is shown the method of mounting the contact block of the sleeper, which also supports the running rails. This contact consists of a hardened cast-steel stud let into a granite block of practically the same size as an ordinary paving stone. The height of the contact above the rest of the pavement varies

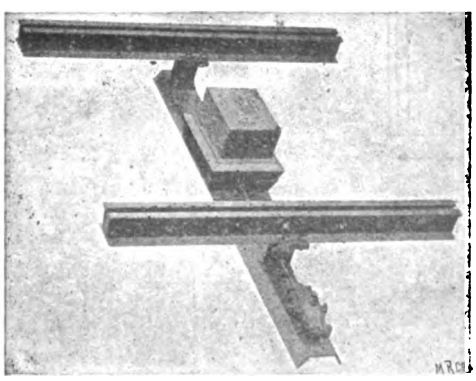

FIG. 5.—Contact Block on Sleeper.

from ¾in. to 1⅛in. The space between the contact and the rails is, with a normal gauge, about 2ft. 3½in. The leakage from the stud to the rail only takes place when the car is over the stud, and even then is not a serious matter—in fact, the company state that the total leakage over the line is not so great as that with the overhead system of supporting a trolley wire. The average distance between the

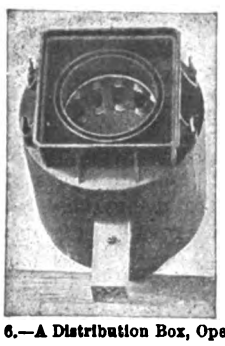

FIG. 6.—A Distribution Box, Open.

blocks is about 13ft. on a straight line, and, of course, considerably less on the curves. At points where the tracks cross it is usual to insert insulated dummy contact blocks to keep the collectors in passing from becoming short-circuited on to the rails. As a rule, about 30 switch gears in connection with the studs are kept in the one distributing street box. These boxes are, as a rule, placed in the middle of the tracks, but they can be placed under the footpath if required. Access is obtained to them by manholes, so that the gear can be readily inspected. A small view of one of these street boxes with its lid off, and before being placed in the ground, is shown in Fig. 6. The arrangement of the lid is such that an airtight seal is obtained, while at the same time moisture does not get through the seal into

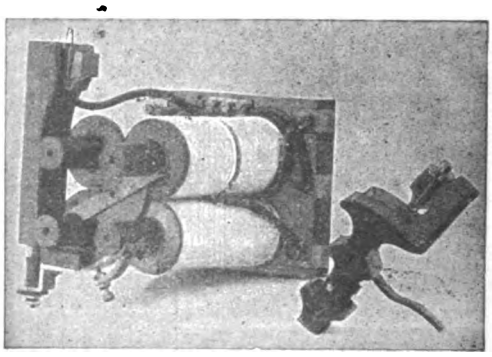

FIG. 7.—View of the Parts of the Contact Apparatus.

the box. These switch gears, or relays, are secured to a wood lining, which is supported clear of the iron sides of the box, so that there is air all round. These boxes are completely equipped before leaving the works, so that all that remains to be done is to insert the wires from each stud.

The individual switch gear for each stud is illustrated in Figs. 7 and 8, from which it will be seen that they

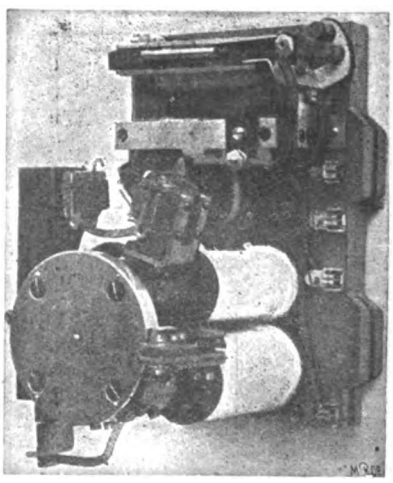

FIG. 8.—Contact Apparatus with Safety Device.

consist of two pairs of magnets arranged with the axes joining their poles at right angles to each other. The one pair then serves to complete the circuit, while the other opens it. The coils are shunt wound, taking about half an

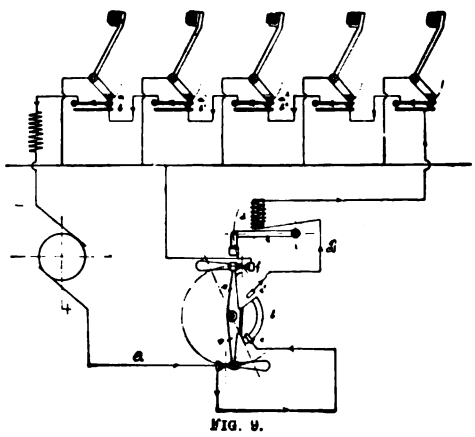

FIG. 9.

ampere at 500 volts. The actual contacts are made and broken through carbon, and it is found that this gives every satisfaction. A switch which had been opened and closed 54,000 times showed practically no deterioration at

Digitized by Google

the point of contact. The chief point at which arcing takes place, if any, is between the brush and the contact point in the street, but this does not occur when the system is working well. This is so because the contact is made by the front relay before it is broken at the back. The only current which remains to be interrupted is the leakage due to the moisture in the street. A special safety device in connection with the relays prevents three studs in a line remaining connected with the feeder without the automatic cut-out coming into operation. This automatic cut-out is so arranged with a lock that it can only be worked by one of the skilled engineers, as the driver and conductors are not allowed to open the same. It has in connection with it a special locking device, shown in Fig. 9, which prevents the cut-out being raised unless all the studs in the circuit are disconnected from the main feeder. In Fig. 10 an illustration is given of the sectional switch, which is also placed in the distribution boxes. The object of this switch is to put the current from one section on to the next as the car passes. If one desires to change the travelling direction when in the middle of a section, the circuit operating the sectional switch has to be closed by hand. These hand switches are placed at intervals of about 65 yards along the track. It will be seen, however, that while this hand switching might be considered a defect, it prevents a car backing along the line without due warning to those cars following. A car can, however, return along the line for a distance equal to the length of its collecting skate without operating this hand switch. Two forms of collectors have been tried on the line at Munich, both of which we illustrate.

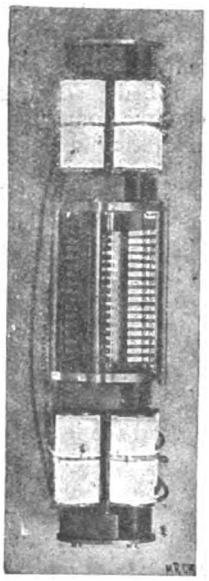

FIG. 10.—Group Switch.

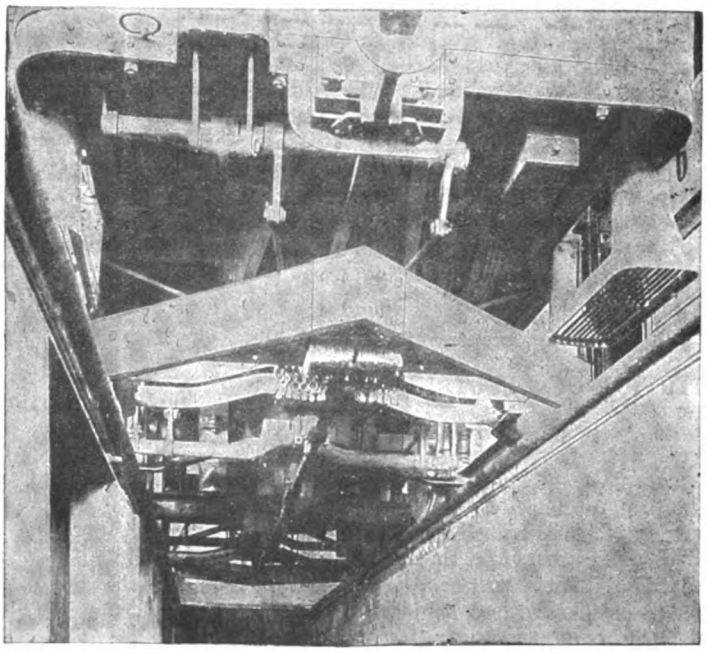

FIG. 12.—Chain Collector.

The first of these (Fig. 11) consists of a wire brush, which is made of steel wire, the other (Fig. 12) consists of a link chain. From actual experience it has been found that these current collectors work well, even with heavy snow and mud on the line. They also have the further advantage that they do not make a noise when passing over the contacts. Both before and behind the current collector another metallic brush is placed,

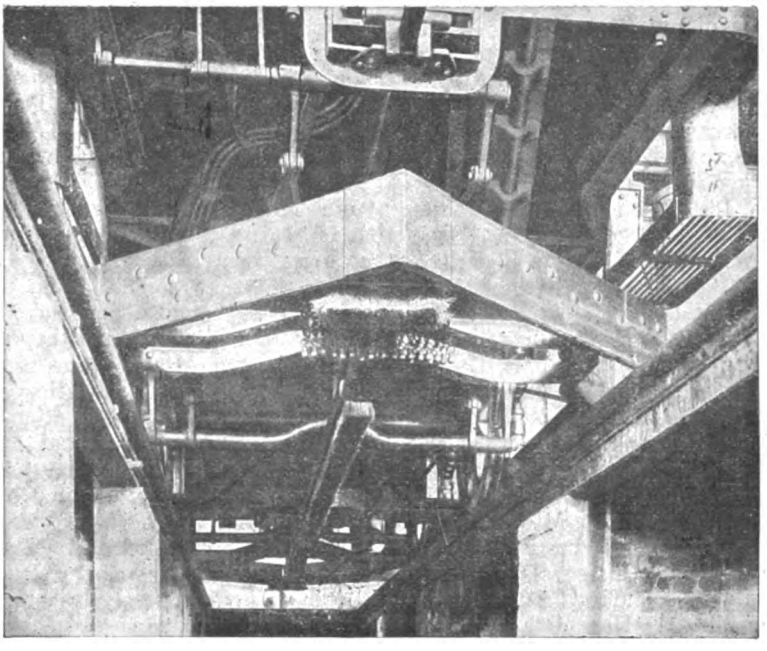

FIG 11.—Brush Collector.

which connects the rails with the contact studs. This prevents any contact being left alive after the car has passed due to faults in the switch gear, as then the brushes would practically cause a short-circuit which would operate the automatic cut-out, and the section on which the car was would then be disconnected until the fault had been remedied. This secures absolute safety to the public.

This system of traction is worked in Munich with a

Digitized by Google

voltage of 640, and curves of current consumption show that the contact system works quite as economically as the trolley system. The great advantage in the system, in our opinion, is that all the automatic switch gear is placed in such positions that it is readily of access for inspection. In the event of one of the relays over the studs not working satisfactorily, it is quite a simple matter for an inspecting engineer to watch the operation of the relay without interrupting at all the traffic, and at the same time slight adjustments can be made, which is not the case when each individual stud has its own switch gear in its own base. The relays also have all their contacts with the system and the direction switches made by plates on their bases, so in the event of a faulty relay it is a most simple operation to replace it. The act of securing of the new relay in the box makes all necessary connections. We also learn that by standardising the various parts, and by erecting the same in their positions in the distributing boxes before the same leave the workshops, the first cost of the system is kept down.

INSTITUTION OF ELECTRICAL ENGINEERS.

The opening meeting of the Institution of Electrical Engineers took place on Thursday week, when Prof. Perry delivered his inaugural address. It was stated that a letter had been received from Lord Kelvin expressing regret at being unable to be present on that evening. The list of donations to the library was then read out, Prof. PERRY stating that Major Crompton was bringing an interesting donation to the Institution—viz., an exploder, used for blowing up bridges and other property in the Transvaal.

Speaking of this exploder, Major CROMPTON said he had brought it along with him for some 8,000 miles, to be presented by the Electrical Engineers to the Institution of Electrical Engineers. The corps would be home in two or three weeks' time, and they would speak more about it then. The exploder, which was a little dynamo in an iron case, had been through several adventures since it was captured, and the train in which it had been brought from the front narrowly missed being held up by the Boers. The dynamo was supposed to be the one used by Commandant Theron for blowing up over a million pounds' worth of property in the shape of railway bridges.

In acknowledging the donations to the library, building fund, and benevolent fund, Prof. PERRY spoke of Major Crompton's gift, and said they were to have during the session something of even more value from him—namely, a paper on his South African experiences.

Prof. S. P. THOMPSON then presented the following premiums and prizes: The Institution Premium, value £25, to Mr. C. E. Groves for his paper on the "Electrical Equipment of Ships of War"; the Paris Electrical Exhibition Premium, value £10, to Mr. S. Evershed for his paper on "A Frictionless Motor Meter"; two extra premiums, each value £10, to Prof. G. Forbes for his paper on "Distant Electric Power Transmission," and to Mr. H. M. Sayers for his paper on "The Calculation of Distributing Systems of Electric Traction under British Conditions"; a premium, value £5, to Mr. A. Russell for an original communication, entitled "How Condenser and Choking-Coil Currents vary with the Shape of the Wave of the Applied E.M.F."; a premium, value £5, to Messrs. C. C. Hawkins and R. Wightman for an original communication, entitled "The Air-Gap in Continuous-Current Dynamos." The Salomons Scholarship, value £50, and the first student's premium, value, £10, were won by Mr. Howgrave-Graham, of the Finsbury Technical College; the second student's premium, value £5, was awarded to Mr. C. B. Nixon for a paper on "Switch Gear for the Generation of the Electric Current"; and the third student's premium, also value £5, to Mr. H. J. Humphreys for a paper on "Permanent Magnets."

Major CROMPTON then proposed that the thanks of the Institution should be given to Prof. S. P. Thompson for the very able manner in which he had filled the chair during his year of office. It was not for him to remind them of Prof. Thompson's services to his profession, but he would remind them that it was during his year of office that that experimental tour had taken place which had been such a great success, and which had done much good in the Institution. This could not have been such a success if they had not had such a man as Prof. Thompson with them, who was acquainted with the various places and who could speak the languages so fluently, and consequently saved them from much of the ridicule to which they might otherwise have been exposed. He considered it mainly due to Prof. Thompson that the tour took place at all.

Mr. MORDEY said it gave him great pleasure to second the vote of thanks. The President of the Institution had more work to do on the committees than at the actual meetings, and Prof. Thompson had helped greatly in organising and dealing with matters connected with the Institution. He thought there had been no more successful president than Prof. Thompson.

Prof. S. P. THOMPSON, in reply, said he thanked them for the kind vote which had been proposed. The statistics of the Institution showed that they were not yet at the highest point of increase. It had happened that the curve of membership rose more during his year of office than it had ever done in any previous year. It was not, of course, due to his occupancy of the chair, but it was gratifying to find it so. During the past year they had had the splendid gift of £1,500 by Mr. H. Wilde, to form a special Wilde benevolent fund. They had also had the legacy of £2,000 from their beloved past-president, Prof. Hughes. The Institution was making great progress in more directions than one, and he was the more confident as to its future in knowing that the chair was to be occupied by a man so capable of maintaining the ever-increasing functions of the Institution. He had known Prof. Perry for 20 years, and had had intimate dealings with him for 12 years as his colleague, and one could never want a better friend than Dr. John Perry. He would therefore, before retiring into the office of ex-president, congratulate the Institution on the choice of his successor.

Prof. PERRY then delivered his presidential address.

Prof. GEORGE FORBES said he had much pleasure in proposing a vote of thanks to Prof. Perry, and to ask that with his permission the address should be printed in the *Journal* of the Institution. They would all agree that they had a president who could form his views in an independent spirit, who could bring forward his ideas in the right manner, and who had no fear of being pleasing or displeasing, as long as he could put them forward. As long as they had such men as Prof. Perry there was no fear of their profession falling behind. There was much, he was sure, that Prof. Perry had kept back which he might have said in the same strain. Everyone of them would like to argue certain points with Prof. Perry, but that was not the fitting time for such arguments. However, there was no doubt that every point raised by Prof. Perry was one for discussion, and they would benefit by thinking of it themselves. He had told them that their profession was in danger of falling behind, and they must all feel that there was this danger. He thought it augured well for their profession in this country that this address had been listened to, not only with such rapt attention, but such manifest appreciation by an audience of engineers. In the early days of electrical engineering he thought Prof. Perry would not have been appreciated so much when speaking of the benefits of theory. The period was, however, past when engineers despised knowledge. The practical man was the man who knew all about his profession, and had imagination and resource to apply it when required. They must all appreciate the value he had put on pure physical science, and also on mathematics, which was the tool which enabled them to put their knowledge into a practical form. It was, he thought, however, Sir W. Siemens who told them that mathematics was a good servant, but a bad master.

Mr. SPAGNOLETTI, in seconding the vote of thanks, said all who had heard Prof. Perry's address would profit by it. Prof. Perry was a man of great energy and power. He had attended the dinner of the Newcastle section the previous evening, and had hurried down to give them the address that evening. He had great pleasure in seconding the vote of thanks.

Digitized by Google

Prof. JOHN PERRY said he knew they would not mind him giving them a lesson. He knew what they thought about the address, and that they would like to argue it out. He knew there was a lot to be said on the other side, but he wanted to say the things he had said. He had heard all the other side from Major Crompton when they were out cycling together. Their new colonies were wonderful things. At Newcastle on the previous evening about 60 had sat down to dinner, and he never saw a better collection of engineering heads. The next meeting was to be on Nov. 22, when a paper would be read by Mr. J. Gavey on "Telegraphs and Telephones at the Paris Exhibition."

Inaugural Address.

BY PROF. JOHN PERRY, M.E, D SC., F R S, PRESIDENT.

(Concluded from page 665.)

Just think of what is occurring at the present time. In England we have cheap coal, and it can be carried easily. In Switzerland and other countries where there is no cheap coal the water power had to be utilised, and power had to be transmitted great distances electrically. This needed high voltage, and as it is difficult to get high voltage with direct-current machines, alternating currents were used, and on account of motor troubles multiphase working has been introduced. What a revelation it was to almost all of us, that visit of a year ago to Switzerland! We saw enormous schemes of lighting and traction and power. We saw electric trains driven by distant waterfalls sandwiched in among ordinary trains, keeping proper time on working railways. We had known that there were great schemes carried out in Germany and America and other countries, and yet all the machines were quite unfamiliar to us. We were very much like what engineers of 1870 would have been if suddenly brought into a generating station. Is it not a fact that some of us, said to be eminent and thought to be practical, asked questions and made remarks which showed that we did not know the most elementary principles of three-phase working. Is it, then, any wonder that the traction schemes now being developed in England, on lines that are certainly not the best for this country of their adoption, are altogether dependent on the use of foreign electrical machinery and employ foreign electrical engineers? I am not putting this altogether fairly, for municipal procrastination has prevented our development, and yet I am not putting it altogether unfairly. We know too little theory.

I am afraid that just now we are in a rather tight place. I would give something to know how we in this room are going to get acquainted with modern electrical engineering. Our usual way of learning is by actual handling of things. But if the millions of pounds' worth of machinery coming to England every year is all foreign and is used mainly under foreign superintendence, our usual method of study is made very difficult. True there are American and German, and, indeed, English publications, which would give a knowledge of the theory, but not, I think, to the average English electrical engineer. I know of many men 25 to 40 years of age who seldom come to our meetings, and who say they are silent in discussions because they cannot be understood. Perhaps these men will find a way to save us all from being left behind. There is much more that I might say in this connection. An individual Englishman may be left behind other Englishmen, and all English electrical engineers may be left behind the rest of the world, but all electrical engineers of the world may even be left behind other appliers of science. It is not merely that the incandescent mantle of the gas engineer is improving and necessitates improvements in our filaments, but in spite of the flourishing conditions of our factories just now, I could give many other illustrations of how we shall all suffer if we do not keep adding to our knowledge. Twenty years ago, when giving some lectures in Clerkenwell to workers in the then flourishing watch trade, I ventured to prophesy the decay of that trade; but I am afraid that the case of Jonah and Nineveh is the only one in which prediction of disaster led to reform. I venture on no prophecy, therefore, because it might harden your hearts.

Much of the evil we suffer from is due to our average young men being pitchforked into works where they get no instruction as soon as they leave school. If ordinary school education were worth the name, and if schoolmasters could be brought to see that we do not live in the fifteenth century, if boys were really taught to think for themselves through common-sense training in natural science, things would not be so bad. But the average boy leaves an English school with no power to think for himself, and with less than no knowledge of natural science, and he learns what is called mathematics in such a fashion that he hates the sight of a mathematical expression all his life after.

And what is the result? English engineers do make a wonderfully intimate acquaintance with the machines and tools that they work with, but when it comes to the manufacture of new things they do it by fitting and trying, by quite unnecessary expenditure of money through trial and error. A machine is made and tried and then another better one, until a good result is arrived at. And this method did well enough in the past, and would do well enough in the future if only we had not to compete with foreigners who can really calculate. It is not all smoke; there is a real danger in this foreign competition unless we mend our ways. There is an absolute necessity for great change in English ways; but there are so many people interested in the maintenance of old methods of working; so many people who think they will lose their bread and butter if a change takes place; so much capital, scholastic and other, invested in our old machinery, that it takes a catastrophe to produce changes. Much of the strength and weakness of England has always lain in her conservatism. We have been talking of standardisation of machinery lately, so I may say that things have been standardised in England for a long time. Now, to get all the good effect of standardisation it is occasionally necessary to go in for wholesale scrapping, and it is this scrapping part of the business that we dislike in England. We here all know that the District and Metropolitan Railways might have been worked electrically years ago just as easily as they will be when we are allowed to begin upon them, but, of course, the scrapping of a lot of steam locomotives was a serious thing. The loss of experience to English electrical engineers, because of this hatred of scrapping, is leading to other incalculable losses. I understand that the whole generating and line plant—the whole machinery of the Boston tramways—has been scrapped several times since they first were driven electrically. Japan has scrapped all her old civilisation just as France did. During the century now dying Germany has made the most sweeping changes in her law and school legislation, and indeed in everything. England and Spain and China, how they differ in this respect even from England's own colonies. Of course, it may be said that English customs have grown during centuries; they are well tried, and there is no pressing need for sudden alteration. I quite agree, but unfortunately this very perfection and fitness of our customs have bred in us a want of flexibility, so that in cases where a sudden change is really necessary, we are disinclined to make the change merely because it is a change, and for no other reason.

No one has ever heard me speak of the decadence of England. When the greatness and the wealth, the manliness and the strength, the healthiness and good life of England are shown forth to the as yet ignorant world in all their magnitude there will be some astonishment. But it is our duty to keep up our high standards. We must change what is bad when we know it to be bad, and not let bad things* continue to exist, parasitic growths, maintained because, on the whole, we are strong and healthy. You will, perhaps, think that this is a very serious exordium when I tell you that I have introduced it all on account of the state of mathematics in our profession. I feel a sort

* Such as our wretched system of weights and measures. Oh, young America and Australia, is it wise to waste a year of every child's life, and years of the life of every business man, merely because we do it in England? You get many of your pedagogues from us, and of course they say that without hundredweights, quarters, and pounds, and Latin declensions and Euclid, the mind cannot be trained. Do you believe them, or are you with open eyes making a great sentimental sacrifice?

Digitized by Google

of degradation every time that I hear a successful, clever old member of this Institution sneering at mathematics. There is a plausibility about his statements; he himself has been very successful in life without much help from mathematics; but, indeed, his sneer is doing a great deal of harm to the younger members who admire his success, who forget that he has succeeded in spite of, and not because of, his neglect of mathematics.

Our knowledge of electrical phenomena must be quantitative to be of practical use; we must be able to calculate. Mathematics is the science of calculation, and we must, therefore, be able to employ, and we all do necessarily employ, less or more mathematics every hour of our professional lives. The draper and the grocer and the housekeeper merely need arithmetic. Everybody now knows some arithmetic. Everybody can add and subtract and multiply and divide, and keep accounts in some simple sort of way. This is due to the fact that arithmetic is no longer taught in the old Greek method with its 27 independent characters (for our 10 figures), the study of which required a lifetime, so that only old men could do multiplication, and they not only needed many hours to do one easy bit of multiplication, but declared that if the art were not practised every day it could not be remembered. Reading and writing and ciphering are now taught to everybody. It used to be that only learned men and philosophers could read, write, and compute. You will remember the charge that was brought against one of Shakspere's characters, who was said to possess mere bookish theory without practical knowledge. "And what was he?" "Forsooth a great arithmetician." Nowadays, when everybody can compute, we should say of the possessor of mere bookish theory, "Forsooth he knows the calculus."

For in mediæval times things were taught in such a way that only a few men had a chance of knowing how to read, write, and cipher. We have been compelled to change all that, the pedagogue has by compulsion given up his mediæval methods of teaching in these things, although in all other matters he retains them. But a time has come when we see that ciphering is not enough mathematics for us to be familiar with; we need a little algebra, we need co-ordinate geometry, we need the differential and integral calculus. The pedagogue tells us that we must follow the orthodox course of study, which takes many years; and some of us, many of us, who have followed the orthodox method find that we have spent so much time and mental power upon it and its thousands of unnecessary tricks and contrivances and philosophy, that we can take in no more ideas. We cannot utilise our mathematics on engineering problems, because we are too old and tired and *blasé* to comprehend these problems. Nevertheless, we are the only people who know mathematics, and so we publish volumes of unmeaning and useless disquisitions on problems that we do not understand. Or we know just enough mathematics to be able to show our ignorance to experts, but quite enough to impress engineers with our knowledge; and we know just enough about engineering problems to show our ignorance to engineers, but quite enough to impress mathematicians, and what we publish is merely as the crackling of thorns under a pot. As for the man who does understand electrical problems, he remembers that there was a something called a study of mathematics at his school, that he did pass certain examinations with much difficulty and tribulation, that the subject had no real meaning to him even when he was supposed to know it, and he now hates the sight of anything that looks like mathematics.

I tell you, gentlemen, that there is only one remedy for this sort of thing. Just as the antiquated method of studying arithmetic has been given up, so the antiquated method of studying other parts of mathematics must be given up. The practical engineer needs to use squared paper. What is the use of telling him that he has taken an unauthorised way to the study of co-ordinate geometry, that he cannot approach it except through Euclid and modern geometry and geometrical conics and algebra and trigonometry. He says the youngest child can be made to understand diagrams on squared paper. So, again, the idea underlying the calculus is one that every child, every boy, every man possesses and uses every day of his life, and there are useful methods of the calculus that might be taught quite quickly to boys, and which it would be a pleasure to boys and men to use continually in all sorts of practical problems, but, of course, the subject of the differential and integral calculus is one that must come at the end of a long course of what is to the average boy utterly uninteresting and unmeaning mathematics. Indeed, the average boy never reaches the subject, whose very names, differential and integral calculus, are enough to drive him frantic. Yes, the schoolmasters say that we must follow the mediæval rules of the game, and all sorts of fine things are said about them, but as a matter of fact we only need to bring a little common-sense to bear upon schoolmasters. At present most of us stick to our arithmetic as a safe and well-tried friend. We compute after the manner of the draper and grocer and housekeeper. In finding out what is the best size of conductor, or armature winding or core, or iron and winding of a field magnet, we calculate by mere arithmetic for one size and then for another; perhaps we have weeks of arithmetical computation before we find the right size of thing to use, and we cannot frame general rules. And some foolish person who knows a little mathematics works at the problem (as we ought to be able to do, but are not), and he frames a general rule, and we laugh at it and sneer at mathematics because he has probably left out of account the most important consideration. We know that the result is wrong, but we cannot say why it is wrong.

Then there are some far-reaching, labour-saving ideas that we simply cannot get into our heads at all—we cannot comprehend them. Am I sinning against the rule as to good comradeship which exists here if I say that some of us are ignorant of the most fundamental fact regulating economy in arranging sizes of conductors? Suppose we find the total cost of installing a conductor of a certain length using one square inch section of copper. We do the same thing for other sizes, and we plot total cost and weight of mere copper on squared paper. I do not care what system we adopt if it is the same system for all sizes, and if we buy our materials from the same manufacturers and use the same kind of labour, our points will lie very nearly in a straight line on the squared paper. Hence increased cost will be proportioned to increased weight of copper, and, indeed, increased total cost will be like the mere increase in the cost of copper, taking a slightly higher price of copper per ton. Some of us, ignorant of the elementary mathematics involved in the problem, think that the mistake has been made of assuming that the cost of an installed conductor is merely the cost of the copper in it, and, of course, he must feel that it is too absurd a mistake not to be laughed over. With an elementary knowledge of mathematics his mistake would be impossible, and without such a knowledge the clever electrical engineer is constantly discovering mare's nests in the investigations which he criticises.

I know of long misleading accounts of the results of good experimental observations which might have been described in a few clear words by the aid of elementary mathematics. I know men who spend on a particular problem 10 times the amount of worrying thought that would enable them to master the easy mathematics that include all such problems. Quite recently one of our most eminent members declared to me that he had not really grasped the reason for small economy at a power station when there is a small load factor until he studied the common-sense mathematical form which has been given in a recent publication. And yet he is a man who has heard much, and read much, and talked much on this subject.

Every electrical engineer has a correct idea of how a transformer acts, or how the E.M.F. in one of the coils of an armature of a direct-current or other generator, or, let us say, a rotary transformer, changes during a revolution, and how the E.M.F.'s of all the coils are combined to produce currents in the external circuits. But through how much mathematical tribulation must most of us have passed from our state of ignorance to our present state of knowledge! It is no wonder that we are disinclined to the study of a new phenomenon which seems as if it might lead us through the like tribulation. The tribulation is least because it is suffered only once if we first learn the calculus method which underlies all our work; it is greatest

Digitized by Google

if we get it up in a completely new-looking form in every new problem. I speak now of what is most difficult in our study, for there is thought required in applying the calculus method. Thus, for example, in multiphase work at the present time, the best mathematicians wonder how it is possible for easy calculation to be made in such a subject. What we want just now is that an electrical engineer, acquainted with three-phase current phenomena, should be so much a master of ordinary easy mathematics that he has a chance of discovering a very simple way of putting the matter before us. At present calculation is easy but tedious, and, indeed, repellant; but I am perfectly certain that a competent man might quickly invent methods of calculation which are not only easy, but short and thinkable. Mathematicians with the requisite electrical knowledge, again, may be lacking in sympathy and humour. I know a book of more than 300 large pages on ordinary alternating currents, and all the information in it is given far more simply in two pages of another book with which some of you are acquainted. Possibly, just now, mathematicians who are electrical, and who have common-sense, have too much other work to do, and we must wait their leisure.

The fact is mathematics ought to be the natural language of the electrical engineer, and at present it is a foreign language; we cannot read or write or think in it. We are at the beginning of our development, like monkeys, whose necessities have increased faster than their powers of speech.

Some of you are aware that a new method of teaching mathematics has recently been introduced in nearly all evening classes in science schools throughout the country.* I wish I could say that there was a prospect of its being introduced in all schools, for it seems to me that this would lead to the result that all young men entering works would be masters of that kind of calculation which is most important in electrical engineering; not merely a few men having this power, but the average men, just as average men can read and write.

I am addressing engineers, men who utilise the results arrived at by scientific workers, men whose profession is applied science. But surely if we are to apply the results arrived at by scientific men, if the laboratory experiment of to-day is the engineering achievement of to-morrow, we ought to be very much alive to all that is going on in the scientific world. All men ought to be far more alive to the importance of scientific work. On the psychological side, it is perfectly exasperating to me to see how few are the men who know that Darwin has given a key to almost all the great philosophical problems of antiquity, and that there is a great mental development accompanying the more evident engineering development now going on in the world. Again, it is the fault of our methods of education that all our great men, our most important, most brilliant, best educated men, our poets and novelists, our legislators and lawyers, our soldiers and sailors, our great manufacturers and merchants, our clergymen and schoolmasters, should remain so ignorant of physical science, the application of which by a few men not ignorant is transforming all the conditions of civilisation. But of all men, just think what it means for engineers to be ignorant of science, or neglectful of its new developments, and of all engineers think what it would mean if electrical engineers sinned in this way.

Except ours, all other branches of industry have taken thousands of years to grow. There were bridge and hydraulic and sanitary and harbour and river engineers in ancient Rome, and such engineers existed thousands of years before the first papyrus was written in Egypt. But no Assyrian tile or Egyptian hieroglyphic or relic from a tomb indicates that telephones or electric motors or electric lights existed before our time. No gradual improvement in our methods of conquering nature led up from small beginnings in our electrical engineering. Our profession has not grown during thousands of years of time, like other professions. It has sprung suddenly, full grown, from the new spirit which is going to rule the souls and bodies of men—the spirit of research in pure science. The new spirit puts knowledge, mere knowledge of nature, as its highest aim. The scientific student knows that all sorts of good must come to mankind from his studies; all sorts of scientific knowledge are sure to be utilised by engineers, but in the pursuit of science the usefulness and utility of the result are of no importance. And are we—we who have received the first-fruits of the labours of scientific men, we the first-born spoilt children of the great parent of all that is to come, we who form the foremost files of the present time—are we going to turn upon our beautiful young mother and say she is useless and ugly, and she hinders our money-making, and that we are willing to kill her for the sake of the burial fee? Thank God, that is the spirit of only a few of us. Have we not, as an Institution, gone to great expense in the publication of *Science Abstracts* in partnership with the Physical Society? That publication has been and continues to be of the very greatest value to all students of pure and applied science who read our language, for it tells them the results of all the scientific work now being done in all parts of the world. And even if some of us do not read that useful publication, do we not know that it is there to read if we like? Do we not know that it is a symbol of our redemption from the yoke of the Philistine? It is one of many signs that in answer to the question which I have asked in this address, we can truthfully say that we are professional men, that our profession has promise of enormous expansion and improvement, and that we are not mere tradesmen.

I am afraid that you will think that I have a personal interest in putting before you the claims for consideration of the pursuit of pure science, because you know that I am trying to defend Kew Observatory from imminent danger. In truth I have no interest in this matter unbecoming a president of this Institution. For two years I have been trying to reason with traction engineers. Like many other electrical engineers, these gentlemen desire to use uninsulated return conductors. If they do so near a magnetic observatory certain records of terrestrial magnetic disturbances are quite spoilt. At Potsdam this sacrilege has been forbidden. At Washington, Toronto, Cape Town, and most other important places, the magnetic records have already been rendered useless. Prof. Rücker and I were asked by the other members of the committee of the Royal Society which was in charge of the Kew Observatory to defend Kew, and with the help of her Majesty's Treasury we thought we were able to insist upon the use of insulated returns in all undertakings authorised by Parliament where harm was likely to be inflicted on Government observatories. I may say that the scheme designed by Mr. Clifton Robinson for using an insulated return conductor in the working of the tramways of the London United Tramways Company, in consequence of our action, was a thoroughly good scheme which it gave one satisfaction to look at—not ugly and not expensive. It seemed to me a fit scheme for any tramway system, however complex, in which overhead conductors are used. You are aware that for an electric railway, or for a tramway where a conduit is employed, it is in every way better, and is in a large scheme actually cheaper, to use an insulated return. We felt therefore very happy, for magnetic observatories seemed quite safe from interference. We were, however, mistaken, for the only clause which we have been able to get inserted in all parliamentary authorisations of undertakings, leaves it to the Board of Trade to substitute other methods of protection than the insulation of the return conductors in cases where these other methods seem to be sufficiently good for the protection of laboratories and observatories, and this is why the Board of Trade appointed the committee which met on Oct. 31 probably for the last time.

Prof. Rücker, Prof. Ayrton, and I have made many tests on the magnetic disturbances produced by tramways and railways, particularly by the Stockton tramways and by the Waterloo and City Railway, and we have had many meetings with the traction engineers, but nothing has yet been decided. I mention this matter, which has given great

* See summary of "Lectures on Practical Mathematics," also the "Science and Art Directory" and the "Reports of Examiners on the Science Examinations of 1899 and 1900"—all published by the Education Department, South Kensington, S W. The reforms now advocated in mathematical and science teaching are all clearly described in a paper read before the Society of Arts in January, 1880.

Digitized by Google

anxiety to scientific men, because I am afraid that some of you may think when you hear of it that I have been acting against the interests of the electrical industry. I beg to assure you that I have been acting in your best interests. As an electrical engineer I ought surely to regret the use of uninsulated returns even if we leave Kew Observatory out of account. Suppose we do not now insulate our returns. Electricity will certainly return by gas and water pipes, and the amount of harm done to those pipes is merely a question of time. Because of the ignorance of legislators and gas and water companies nothing is said just now, but will nothing be said at the end of 10 or 20 years, when pipes are found to be eaten away everywhere? And if by a slight increase of expense, or, rather, as I think, actually no increase of expense, but merely a little increase in inventiveness and common-sense on the part of electrical engineers, this evil may be entirely prevented, surely it is in the interests of all of us that insulated returns should be insisted upon. But even if we do not insist on insulating the returns in all systems, surely something may be said for the giving of this protection on lines near such a magnetic observatory as Kew. Even the magnetograph records now being made have been continuous for 45 years, and if Kew is interfered with no sum of money can compensate for the interference, for if the Observatory were removed the future observations would have no link with the past. An engineer in this room declared that it seemed to him an injustice to hamper the progress of electric tramways "for the sake of making observations that never have given, and never may give, to the world any important results." Now, it is not so much on account of Kew that I object to this sort of observation, as to its general spirit of antagonism to scientific research.

There is no doubt that the answer to the old question which Gilbert might have asked 300 years ago, "What is the cause of terrestrial magnetism?" is very jealously hidden from us by Nature. The earth probably contains much iron, but its great internal heat seems to forbid our imagining the iron to be magnetic. The assumption that a negative electric charge on the rotating earth will explain things, requires such an enormous charge that this assumption has been discarded. There are annual and diurnal variations of a fairly regular kind; there are storms which have some relation to the Aurora Borealis, to sun-spots, and to earth currents. There are small sudden changes which seem to occur almost instantaneously all over the earth. Observations of these things may be useless from some points of view, but scientific men have been and continue to be willing to give up time and much money for this object. Utilitarians had to be cajoled through superstition to allow observations of the stars to be carried on in ancient times, and we have no such cajolery to offer. We simply say that it has been through this sort of useless-looking method of working that all our progress in science has come.

Engineers descended from men who sneered at Cavendish and Franklin and Volta and Oersted and Ohm and Faraday, are you who utilise the results of the work so sneered at, and pile up fortunes in consequence of it, are you the men to sneer at and ridicule the scientific work of the present day because it seems to you useless? Tell us a better method of observation; give us better suggestions as to what these magnetic phenomena may mean; but the past record of scientific observation enables us to laugh at you when you say that magnetic observations may never give the world any important results. Was Nature ever so open and yet so closed about a secret as she is about this one of terrestrial magnetism? Was there ever one whose revelation promised so much? How very little we know of electricity and magnetism! Does the mere motion of the earth, taking no account of electric charges at all, cause it to be magnetic? Almost anything is on the cards. Surely I need not appeal to your cupidity, but it is quite possible that our knowledge of this secret may enable us to tap a tremendous store of Nature's energy.

Gentlemen, this is not a trades union, and it is not a society for the furtherance of pure scientific research, but it is a society of professional men who recognise the past services of scientific observers with gratitude and respect, and hope for greater ones in the future. And shall it be said of us that our gratitude is not greater than that of Judas, to whom, indeed, 30 pieces of silver was doubtless a large sum; that "we have given our hearts away a sordid boon"; and that as to our future hopes we are willing to sell our birthright for a mess of pottage.

THE TELAUTOGRAPH.

In our issue for July 27 we gave a general description of the telautograph, which is the invention of Mr. Foster Ritchie. We were at that time debarred from going into technical details for reasons connected with the Patent Office routine. Now that the patent rights are fully secured to the company, we have again examined the instrument and were permitted to take photographs, from which the accompanying illustrations are prepared. We do not propose to recapitulate the general description now, but merely state that the instrument is one for transmitting writing and diagrams in such a way that the personality of the sender is displayed in the message received. In fact, the record at the sending end and the message received are exact duplicates. Figs. 1, 2, and 3 show the instrument by which this is done, while Fig. 4

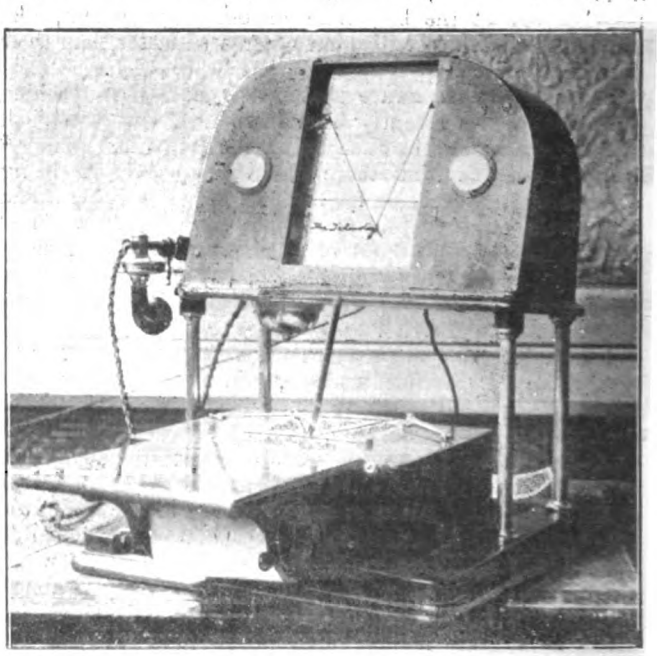

FIG. 1.—The Telautograph with the Cover on, and with the Pen supported as in the act of writing.

is a diagram of the circuits. This diagram includes only the sending parts of one instrument and the receiving apparatus of another, in order for the sake of clearness. The working is then as follows: At the transmitter two distinct currents flow from the battery A, through the switch, H, and the wires 1 and 2 to the rheostats, B B, thence by the brushes and arms, C C, to the line wires 3 and 4. The two currents then pass through the swinging coils, D D, of the receiving instrument, and through relays, E' and E, to the battery Z, and thence to earth. The movements of the brushes, C C, throw more or less of the resistance of the rheostats, B B, into the respective circuits, thus changing the amount of current passing to each of the line wires. These changes cause the swinging coils, D D, to move through angles exactly equal to those through which the brushes on the rheostats, B B, have been moved.

The linkwork by which these rheostat lines, C C, are moved is shown in the photographs. In the centre of this linkwork is the pencil with which the message to be sent is written. The recording pen is at the receiving end, connected by an exactly similar series of links to the moving coils of the receivers. Thus it follows that any one position of the pen on the paper corresponds to two definite angles only of the arms, C C. These two angles are reproduced exactly on the moving coils of the receiver, and in consequence the position of the receiving pen exactly

Digitized by Google

corresponds to that of the sending pencil. The induction coil, F, at the transmitter is controlled by the vertical movement of platen, G, which is under the sending pencil, allowing the primary circuit to be completed through the contact, 5, when the plate is pressed down by the act of writing. This causes the induction-coil hammer to vibrate, sending alternating currents through the condenser, I, to line 4, and by wire 6 to line 3 Owing to the

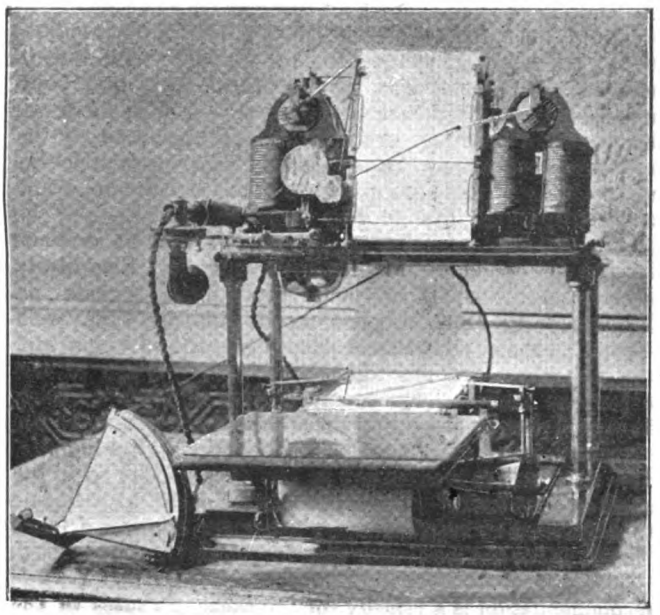

FIG. 2.—The Telautograph with Receiving Pen dipping in Ink Well.

great self-induction of the coils, D D, and the relays, E′ and E, at the receiver, these alternating currents pass principally between lines 3 and 4 by wire 7 and the condenser, L, thence through the small relay, K, and the wire 8. This alternating current then causes the relay, K, to control the penlifter, M, by means of a local current through wire 9, the contact 10, and the wire 11. The relays, E′ and E, are very sensitive and are operated by

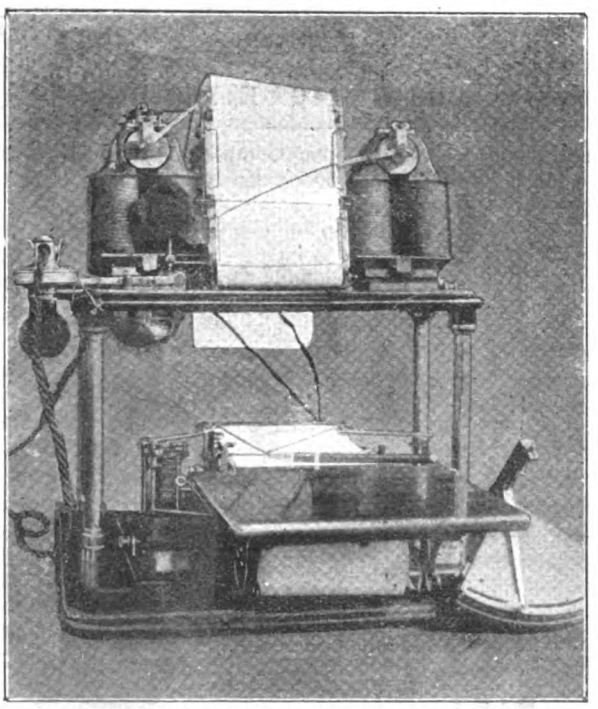

FIG. 3.—Another View of the same.

very weak line currents. The relay, E′, controlling the paper-shifter, P, also opens the local circuit controlling the pen-lifter, M, so that a vertical line is not made by the pen when the paper is shifted. The relay E, in conjunction with E′, controls the signal-bell, N. For this purpose the transmitter is fitted with a push key, not shown on diagram, which breaks the line 3, and puts battery A direct to line 4, thus allowing a local current to pass through contact 15, wire 12, contact 13, and wire 14, to the bell, N. The lever, O, on the transmitter is operated by the pencil, and is mechanically connected with the paper-shifter. Its movement also operates a contact at 17, thereby breaking current from the lines when pushed in direction of the arrow, and actuating the paper-shifting apparatus at the receiver as already described. The wires marked + and − in the diagram are connected to their respective poles of the batteries, Z and A. It will be noticed that the batteries at either end are in series when signals are being sent, but that they are in opposition when no signalling is taking place. It seems to us that in practice the earth will not be convenient for a return, and that a third wire will be preferable. The whole instrument shows

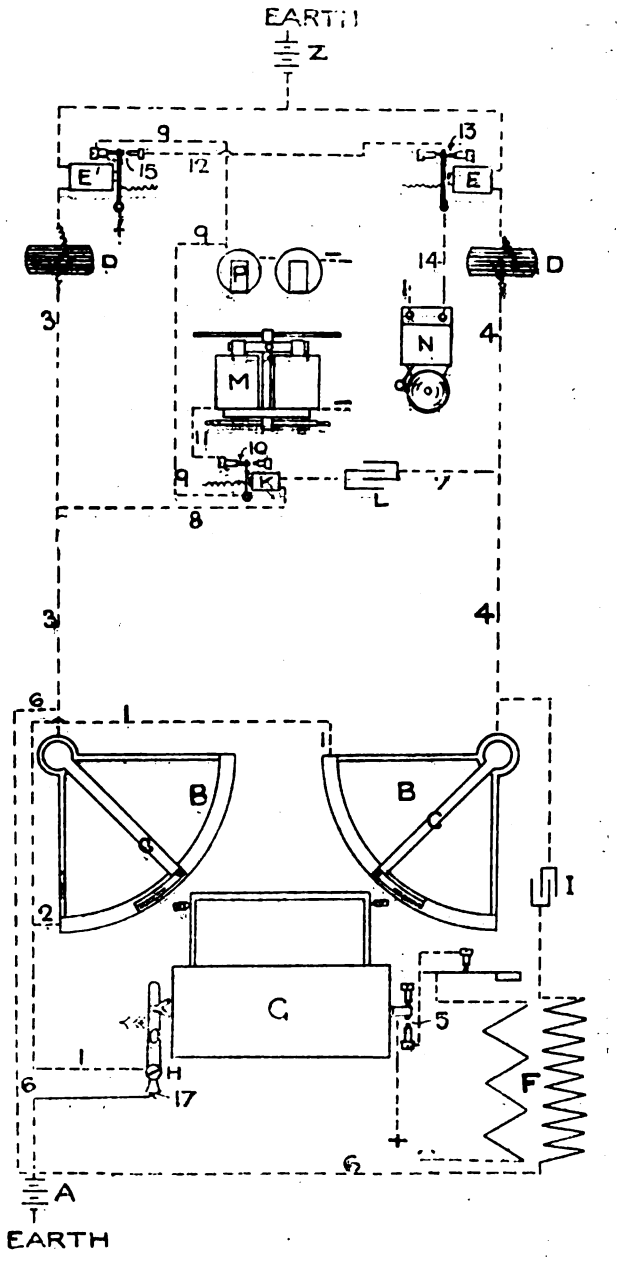

FIG. 4.—Diagram of Connections.

a wonderful combination of electrical knowledge and mechanical skill.

THE SLOUGH REPORT.

The report of Lieutenant-Colonel Yorke on the enquiry into the accident at Slough has been published. Colonel Yorke states that the driver takes the sole responsibility for the accident, and does not attempt to inculpate any other person. The report contains references to the failure of the fireman and the guards of the train to observe the positions of the signals, as was their duty according to rule, to the use of the "Section Clear but Station Blocked"

Digitized by Google

rule for such a train as that concerned, and to appliances which are designed to give supplementary indications of the positions of signals, some of which appear to have been brought under the inspector's notice, a few of which he states are under trial. He, however, appears to consider that with the most careful maintenance such apparatus might fail, and that drivers being made less alert by reliance on such mechanism, would be likely to pay less attention than at present to the ordinary signals.

As an expert in railway working Lieut.-Colonel Yorke's opinions are worthy of the most careful attention. Where blame is apportioned as the result of careful sifting of the evidence adduced there is nothing to be said. It *was* the duty of the men concerned to carefully observe the positions of the signals, according to rule, and in so far as they neglected to do this they are blameable. But when suggestions are made with a view to the prevention of similar occurrences, criticism becomes legitimate. Consider some extracts from the inspector's report which refer to the driver:

"He has a good character for sobriety, and his appearance is in his favour."

"But since the accident his eyesight has been tested by that eminent specialist, Dr. Cross, of Bristol, who certifies that Woodman's eyes are sound; that his power of vision for distant objects is, with two eyes together, about two-thirds of what it should be, and that his sight, though 'old,' is for practical purposes with good-sized objects 'good,' while 'his colour-vision is particularly acute.'"

"Nor is there any ground for supposing that he was taken suddenly ill. He says he was not asleep. But it seems to me he might be in a drowsy state without being aware of the fact, or that his attention may unwittingly have wandered from his duty, and his mental faculties have become temporarily deadened or inactive and have so produced that condition which is familiarly known as 'absence of mind.' It is to one or other of these latter alternatives, or perhaps a combination of the two, that I am inclined to attribute Woodman's failure to observe the signals at which it was his duty to stop. Woodman has nearly completed his sixtieth year, but he has all appearance of a man 10 years older than this. His age and the fact that he had been up since 5 a.m. probably predisposed him to the condition which I have suggested, of which the taking of food may have been the more immediate cause."

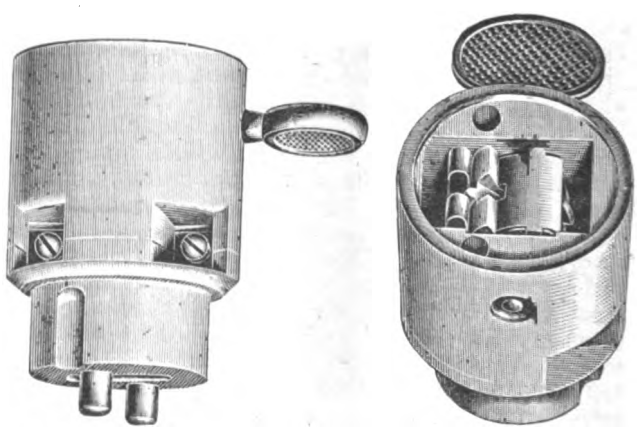
Colonel Yorke considers that the chief lesson taught by the accident is the necessity for the periodical examination of all drivers after passing the prime of life to ascertain their fitness physically and mentally without waiting until they are 60 years of age, as at present. And yet Colonel Yorke attributes the driver's failure to "absence of mind," and the report tends clearly to show that to outward appearance the driver's condition was normal. How will periodical examinations tend to show a predisposition to absent-mindedness? If a man is ever on the alert, it will be when he knows he is undergoing an examination, upon the results of which his bread and butter depends. Examinations for fitness physically and mentally involve the establishment of standards. Who will set the standards, and who also will determine at the periodical examinations whether a man rises to them? If a man passes the standards imposed, he is practically given a certificate of fitness. If after such certification he contributes to an accident, will he be criminally liable? Will the person who certifies his fitness be in any way responsible? Do not all classes of railway workmen undergo a continuous examination by their contact with their superiors? Do not drivers have to submit now to periodical eyesight tests without waiting until they are 60? If the taking of food predisposes to absence of mind, will periodical examinations neutralise the tendency, or should the taking of food when on duty be prohibited?

It seems very strange that an inspector of the Railway Department of the Board of Trade should show such distrust of supplementary apparatus to enable drivers to ascertain the positions of signals. The old, old fear of diminishing the alertness of the men by contributing towards the certainty of their obtaining proper notice of the indications exhibited for their guidance is very manifest. Coming from a representative of the department of State which compels railway companies to interlock their points and signals to prevent fouling combinations being made by the signalman, which compels the use of apparatus for indicating the condition of the line at all times, and which favours still further restrictions on the signalman's action such as are obtained from lock and block working, the remarks on supplementary apparatus for the advantage of the driver seem very strange indeed. Such errors as a signalman could make without the protection compulsorily afforded him, and some that he can make now, would, we may be sure, be the result of misapprehension or absent-mindedness. The driver, however, controls the situation in every case. It is for his guidance that the whole of the elaborate system of signalling is set in operation. If he misapprehends the position the whole system with all its checks goes by the board, and those who control him ordinarily are powerless to stop him, or to call his attention promptly to the error, as is evidenced by the case being considered. But to give the driver such checks upon himself as are given to the signalman would apparently teach him to rely upon the checks, and he would pay less attention to the signals than at present. In the discussion on Mr. Hollins's paper on "Electrically Interlocking the Block and Mechanical Signals on Railways," in 1897, Lieut.-Colonel Addison said, with regard to the advisability of adopting lock and block, and the objections brought against its use: "Some of the objections really apply to any system of *block* working. It is said that by providing these safeguards you make the signalman into a mere machine and destroy his intelligence. I do not think it is necessary in the present day to argue at all on that basis." These remarks are quite as applicable to objections to supplementary apparatus for the driver's benefit as for the particular case for which they were used.

It is difficult to ascertain in what respect Colonel Yorke's recommendation is a remedy for the cause or causes of the accident, as shown by the report. Examinations such as are suggested in this case, or as suggested by the coroner's jury in the Bermondsey case lately, will not confer on the examinee the faculty to always do the right thing at the right time. Such a faculty is instinctive, and the splendid record of English railways shows how widely it is spread amongst those engaged in working so enormous a traffic. Such momentary aberrations are the common lot, and it is only in the case of those saddled with large responsibility that the results are so terrible. The true remedy for such lapses is to provide means for calling attention to them as they occur.

A HIGH-VOLTAGE KEYHOLDER.

The International Electric Company, of 55, Redcross-street, E.C., are now placing on the market a new type of high-voltage keyholder, which is designed with a view to prevent arcing. In this holder the switching-off is done in one direction only, as if the handle is turned to the left the switch remains inoperative. The fitting is very highly



insulated, as the switching movement is entirely enclosed by the porcelain body, and arcing is thus rendered impossible. The switch would, it appear, possess the advantage of having a quick breaking action, and of making a good rubbing contact when switched on. The holder is not any larger in size than the ordinary switch-holder, and it has a very neat appearance. From the above illustrations the working of the apparatus can be fairly well understood,

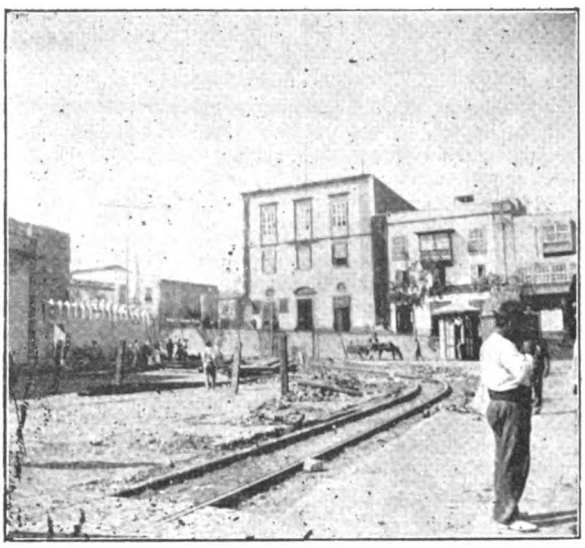
MEMORIAL STONE LAYING AT KEIGHLEY.

The election of the Mayor of Keighley, which took place on Nov. 9, was followed immediately by an interesting ceremony—namely, that of laying a memorial stone at the new electricity works. The Mayor (Mr. H. C. Longsdon), who had just been re-elected, performed the ceremony of laying the stone, being presented with a silver trowel and wooden mallet by Alderman Brigg. We have received from Mr. Smyth, the borough electrical engineer, a description of the works. In July, 1899, the Royal assent was obtained to the provisional order giving the Corporation power to supply electric energy within the borough. The designs for the works were started shortly afterwards, and a scheme drawn up to include a supply of electricity for lighting and power, provision being made for a probable demand for a supply of power for the tramways. The scheme was approved by the Corporation on Dec. 19, 1899, and application was made to the Local Government Board to borrow the necessary capital. Tenders were obtained for the supply of machinery, mains, etc., most of the contracts being placed in April and May, 1900. On May 23 a Local Government Board enquiry was held at the municipal offices into the application for borrowing powers, no public opposition being raised. The sanction of the Local Government Board to a loan of £34,600 was duly obtained. On July 3 building operations were commenced on the Coney-lane site, and have proceeded extremely well, in spite of bad weather and difficulties which have been experienced in the foundations of the building. One of the main features of the works will be a large and commodious block of offices, two storeys in height. The offices have been designed to meet all future requirements, and a corner of the site, in a prominent position, but which was useless for machinery purposes, has been utilised. The offices consist of a general office, chief engineer's and assistant engineer's offices, testing and show rooms. Immediately behind the offices, but separated from it by a passage, is the accumulator-house—a building 60ft. long by 26ft. wide—where a storage battery of 256 cells will be placed. This building is lofty and well ventilated, and is separated as far as possible from the other buildings, so that a minimum of inconvenience is felt from the acid spray during charging. Adjoining this, and leading into the engine-house, will be a well-lighted workshop and stores. The engine-house, which has a main entrance in Coney-lane, is a well-lighted building, 85ft. long by 40ft. wide and 24ft. high. The walls will be lined inside with white glazed tiles, which will give a light and clean appearance to the interior. The machinery will consist of three engines and dynamos, having a total of 800 h.p., and a switchboard for regulating the supply. The engine-house will be capable of taking 3,000 h.p. of machinery without further extension, and the machinery will be ordered as the demand increases. The high-speed vertical type of engine direct-coupled to the dynamos has been adopted. The boiler-house, built parallel with the engine-house, is 85ft. long by 75ft. wide. Two Lancashire boilers, 30ft. long by 8ft. diameter, will be used at first, there being room for six boilers of this size. This part of the works is in close proximity to the sidings of the Great Northern Railway Company, and when the demand is sufficiently great to warrant the expenditure, a special siding will probably be run into the works for the coal supply. Water for condensing purposes will be obtained from the River Worth, the Corporation having recently obtained rights from the Great Northern Railway Company to use water for this purpose. Continuous current at 230 volts will be supplied in the town, the mains being arranged on the three-wire system. Continuous current being specially suitable for driving motors, it is expected that there will be a considerable demand for a supply of power as soon as the works are started. The Electricity Committee, in view of the fact that within a short time they may be called upon to supply electric power to the present tramways, have ordered engines and dynamos which can be used for either lighting or tramway work, and provision has been made, during the laying of the cables, for laying tramway cables when required at a minimum of expense. It is anticipated that a public supply of electricity will be available by Easter, 1901, or within a period of about 15 months from the date of approval of the scheme by the Council. Mr. J. M. Smyth, the borough electrical engineer, is responsible for all the works in connection with this undertaking, and he has been very ably assisted by Mr. H. Chilvers, his chief assistant, who has carried out the whole of the work relating to the buildings.

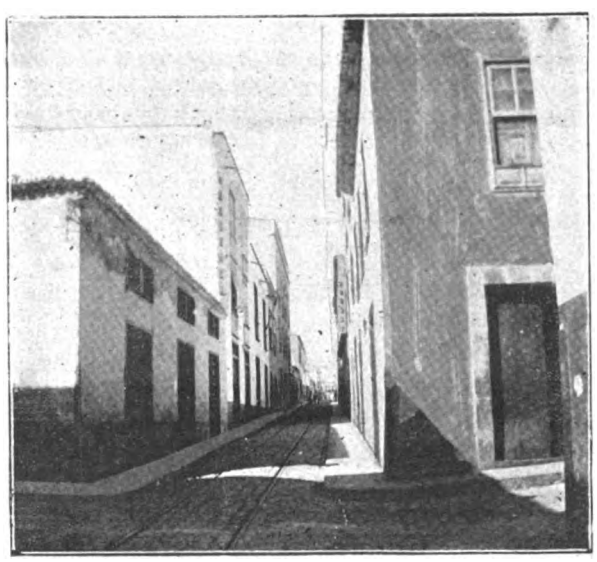
THE TENERIFFE ELECTRIC TRAMWAY.

The two photographs we reproduce herewith were taken of the electric tramway which is to be opened for working shortly in Teneriffe. One of these was taken from the



The Teneriffe Tramway from the Harbour.

harbour, while the other shows the extremely narrow street through which the cars have to pass. The actual space between the footboards of the car and the kerbs when the car is passing by the street will be only 15in. on either side. We suppose the inhabitants of Teneriffe would object to the drastic procedure adopted in Japan when



The Teneriffe Electric Tramway in Narrow Street.

laying down electric tramways. We understand that in certain towns in that country the best routes were selected for the tramways, and if the houses were then found to be too close they were pulled down, and their owners expected to re-erect them farther back from the street line at their own expense.

LEGAL.—The adjourned case of the Mayor and Corporation of Wolverhampton *v.* the British Electric Traction Company, Limited, was heard yesterday afternoon in the Chancery Division of the High Court, when judgment was reserved.

BAKER STREET AND WATERLOO.

Consider that such a thing as a passenger steam railway was unknown at the beginning of the century, that goods were largely carried by means of pack-horses, and later by broad-wheeled wagons, passengers by horses or stage coaches, that during the century steam has come and reduced travelling to comparative insignificance, while at the close of the century electricity seems destined to largely supersede all other means of transport, we then recognise that progress has been extremely rapid. Semiramis is the first ruler history records as having ordered the construction of roads, but the business of civilisation till the dawn of the nineteenth century was principally transacted by water carriage. Rome, indeed, built magnificent military roads, but till the advent of steam intercommunication between inland towns was difficult. It is probable that the improved methods of intercommunication are, in a higher degree than the spread of education, answerable for the progress of civilisation. So recently as 1835 seven coaches started daily between London and Edinburgh, performing the journey in forty-eight hours. Within a period of sixty or seventy years the time of this journey has been reduced to only eight to nine hours. Practically it was seventy years ago—in 1830—that the first railway for general traffic in passengers and goods between Liverpool and Manchester was opened, and immediately thirty-four out of the thirty-five coaches previously running between the two places were discontinued, the remaining one being supported by passengers to intermediate places. We are almost tempted to put the starting point of modern life to the year 1851—the time of the first great international exhibition—though by the end of that year nearly two hundred and fifty millions of capital had been expended on British railways. Within the last twenty years the first electric trams—Brighton Beach in England, Portrush in Ireland—have been opened in this country. From these rudimentary efforts we have passed to the stage when the equipment not only of many miles of tramways, but of full-blown railways is electrical, and further railways of great importance have been constructed and are in contemplation which could be adequately equipped upon no other system. The South London and the Central London Railways are in full working order, and during the week the prospectus of the Baker-street and Waterloo line has been issued. The share capital of this line is £2,385,000, with boorrwing powers £794,000. The directorate consists of men familiar with railway work, and if success is to be attained, they should know how to obtain it. The thoughtful mind contemplating the progress made in so short a time almost stands aghast at its rapidity, and yet had there been no legislative restrictions it is more than probable that progress would have been still more rapid. It is hardly our purpose to discuss the prospects of the above line. If we did so, we should hardly feel inclined to be pessimistic, seeing that history teems with cases

Digitized by Google

where the increase of convenience to the travelling public has met with due pecuniary reward. Indeed, it is difficult to find exception to this rule, hence, while there may not at first sight seem to be in it the promise of the "twopenny tube," it must be recognised that the new line provides a very convenient means of communication across London and between the termini of many main lines of railway. One of the earliest papers to influence the introduction of steam railways appeared in 1825 in the columns of the *Scotsman*. Its first sentence reads thus: "There is no single circumstance so essential to the improvement of a country as abundant and easy means of internal communication." Those words are as pertinent now as they were seventy-five years ago, and if instead of "country" we write "city," the conclusion is just as apt.

THE ELECTRIC LIGHTING OF LONDON.

We understand from a parliamentary notice that the Board of Trade are proposing to introduce a Bill in the new session of Parliament for the adjustment of the electric lighting areas of London. The main object of the Bill will be to make the boundaries of the electric lighting areas conform with the areas of local government fixed by the London Government Act of 1899. In the notice given all the provisional orders granted up to the present for areas in London are scheduled, and one learns that powers will be sought to confirm arrangements made between companies and companies or between local authorities and companies with the above-mentioned object. While in certain cases the matter of the readjustment of areas will not be at all difficult, there are others in which we foresee that great objections will arise from the interference to vested interests which will result from the reduction of powers previously granted under the Electric Lighting Acts. How these difficulties are to be overcome remains to be seen, but it is doubtful whether it is worth while to undertake alterations in the area of supply which will involve a heavy compensation in order to make electric lighting areas and the new municipal areas agree. As seventeen local authorities and ten companies are interested in the proposed Bill, there will be ample employment for the members of the Parliamentary Bar.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MANCHESTER CORPORATION CONTRACTS.

SIR,—"Does the punishment fit the crime?" Mr. Higginbottom does not appear to have committed any heinous offence, yet the punishment is, perhaps, the hardest that could be inflicted upon a public man, especially one who has served his corporation with conspicuous ability.

Out of 25 charges brought against him, 23 have gone to the wall. Does not this speak volumes? Had there been two items dealt with, or practically one, the impression on the public mind would have been very different; for, after all, it is only a question of sub-letting contracts for cranes or parts of cranes to Messrs. Higginbottom and Mannock, the acceptance of which was indiscreet, but could certainly not be described as "altogether improper." If that were so, then why should a member of a private firm not do business with a corporation of which he is also a member *when* a director of a limited company can do so, having only to disclose the fact; when a member of Parliament associated with a limited company can do so with the Government, and even when a member of the Cabinet similarly situated can do so? If this is the conclusion, then the sooner a very large number of members of public bodies proceed to convert their establishments the better.

1. It has not been shown that the Corporation of Manchester lost a penny by giving contracts to Messrs. Pearn and Co., Limited, etc., and through them to Messrs. Higginbottom and Mannock.

2. It has not been shown that the Corporation of Manchester did not get full value for money.

3. It probably could be shown that the Corporation of Manchester have saved money by giving repeat orders indirectly to Messrs. Higginbottom and Mannock.

4. The excellence of Messrs. Higginbottom and Mannock's cranes is generally acknowledged; therefore by buying directly or indirectly, the Corporation of Manchester were not buying inferior goods.

5. Why was this attack kept in the dark until the eve of Mr. Higginbottom's election to the highest honour, next to its freedom, that the city of Manchester can bestow, when the first sub-contract to which his judges take exception dates back as far as 1892? It is strange that the persons who loaded the guns, if not the person who fired them, should have attached no importance to this matter of sub-contracts until *Oct. 27, 1900.*

To conclude, the city of Manchester has undoubtedly lost a valuable adviser, and its Electric Lighting Committee a most able leader—as a scientific journal admits—and difficult to replace, in order to start a cleansing scheme that may or may not be much needed, but too drastically applied in this instance; whereas people who have done infinitely worse have held high office, and still "flourish as the green bay tree."

It is to be hoped that this incident will not close the public career of so capable a man.—Yours, etc.,

Nov. 13, 1900. ELECTRIC.

[N B.—Our correspondent may question the consistency of the law, but the fact remains that Mr. Higginbottom's conduct in taking sub-contracts was in the present state of the law an illegal act.—ED. *E. E.*]

REVIEWS.

Manual of Electrical Undertakings, 1900-1901. Compiled under the direction of EMILE GARCKE, M.I.E.E., F.S.S., Donington House, Norfolk-street, Strand, W.C. 12s. 6d. net.

The fifth annual edition of this manual, just published, well illustrates, by its annual increase in bulk, the growth of electrical undertakings within recent years. Vol. I. contained 172 undertakings in 470 pages, the latter now number 1,272, and are devoted to 653 undertakings. While the number of works has thus increased more than fourfold, the capital has only just doubled itself. The 172 undertakings in 1896 had a capital of £61,109,000, and the capital of the 653 in 1900 only amounts to £123,636,000—another proof, if it were needed, of the fact that capital does not flow as freely in support of electrical industry in this country as it does on the continents of Europe and America. A number of interesting historical notes are added, and the usual carefully compiled statistical tables, carried up to date, are appended.

THE AUTOMOBILE CLUB DINNER.

In the Whitehall Rooms of the Hôtel Métropole on Wednesday night Mr. Roger W. Wallace, Q.C., the president, took the chair at the annual dinner of the Automobile Club of Great Britain and Ireland. Many notable men were present, including Lord Borthwick, the

Digitized by Google

Hon. C. S. Rolls, Sir R. Harrison, Colonel Crompton, Mr. Stuart-Wortley, M.P., Mr. Cumming Macdona, M.P., Mr. Scott Montagu, M.P., Prof. Boverton Redwood, Mr. C. H. Moore, etc.

After the loyal toasts, the CHAIRMAN gave the "Navy, Army, and Reserve Forces."

General Sir R. HARRISON, Inspector-General of Fortifications, in replying, pointed out how much the services depended on mechanical power. The transport of ammunition was getting beyond the power of animals. Unless there was a river or a railway it had become difficult to carry on a campaign. Mechanical power on the lines of communication and even on the battlefield for heavy guns was necessary, and automobiles there had their chance. The Royal Engineers had been trying to promote the use of traction engines. These used to be cumbrous, but had done good service. Twenty-four engines were sent out to Africa. Some were wrecked at Las Palmas, but those that arrived had done useful work where there was no railway. Engines had also been sent out in connection with the searchlight, as Colonel Crompton could tell them. As to the future, Lord Roberts had recognised the value of these engines, and the Royal Engineers would investigate the question of the best type of machine. If another war should occur, this country would be better prepared with automobiles.

Prof. BOVERTON REDWOOD, in giving "The Houses of Parliament," expressed the hope that they would see to it that what Parliament gave would not indirectly be taken away as regards motors, through the powers given to the local authorities.

Mr. STUART-WORTLEY, M.P., proposed "Success to the Automobile Club," to which Mr. SCOTT MONTAGU, M.P., replied, and the proceedings closed with the toast of "The Visitors."

THE AUTOMOBILE CLUB TRIALS OF ELECTRICAL VEHICLES.

We have received from the Automobile Club a most interesting series of figures, which, however, have yet to be confirmed by the Judges Committee, concerning the trials which took place last week. These may be taken to represent the most unfavourable results which can be obtained from electrical vehicles, as the roads were in a terribly greasy condition owing to the continued rains; also the routes chosen were not unduly favourable, as the cars had to go over some of the most hilly roads in the county of Kent. We abstract from the figures we have received the following information concerning the most successful vehicles. Thus the vehicle entered by the British and Foreign Electrical Vehicles Company, of 11, Devonshire-square, E.C., succeeded on Tuesday in traversing without recharging a 59-mile course. The total time on the journey was 5 hours 52 minutes, but allowing for stops, which were not due to any fault of the vehicle, the time would be reduced to 5 hours 24 minutes, giving an average speed of 10·92 miles per hour. On the Wednesday a run of 24¼ miles was made, at an average speed of 13·47 miles, and more would have been done but for an accident due to side slip. On the Thursday the vehicle did 29¼ miles in 2 hours 22 minutes, giving an average speed of 12·29 miles per hour. The last day of the trial the route selected was over a more level road, and the state of the road was rather better. On this day the vehicle in question went 60 miles without recharging, the average speed, including small stops, was 9·8 miles per hour, while the average running speed was 10·7 miles per hour. The total weight of this car was 48½cwt.

The car entered by the National Motor Carriage Syndicate, Limited, of 37, Walbrook, E.C., consisted of a Joel car to carry two persons, fitted with a Rosenthall battery and Joel motor, the total weight of the car being 19cwt. On Tuesday the car travelled some 34¾ miles, exclusive of a detour made in consequence of the driver losing his way. The driver seems not to have been up to the mark in health, as several stops had to be made on his account. The time taken was 5 hours 14 minutes, the average speed of the car being 6·6 miles per hour. Lubricating in this car seemed to be a rather serious trouble. On Wednesday the first stop was caused by a chain coming off, and on attempting to start again the chain mounted the pinion and bent it, the car having to be pushed a few hundred yards to a blacksmith's. After a stop of 1 hour 18 minutes a fresh start was made, and the run completed with sundry small stops to examine the motors, etc. The total distance covered was 30¾ miles, an examination at the end of the run showing a bent axle. On Thursday the car only went five miles, and had to return owing to one motor not working properly. On Friday, a proverbially unlucky day, the car started off at 10.30, and at 11.4 had a punctured tyre. It was restarted, and returned to Chislehurst after four punctures had had to be repaired. The Electric Motive Power Company, Limited, of 75, Caistor-road, Balham, entered a car to seat four, fitted with the company's batteries and a four-pole enclosed series motor, the weight of the car being 30½cwt. This car on Tuesday ran a total distance of 33 miles at an average speed of 8·25 miles per hour. The hill at Orpington seems to have been rather too much for the motor, and the observer had to get out and two people pushed the car up that and the next hill. Pushing was the order of the day, as after the fifth stop the car had to to be helped in this way. The total time taken on the journey was four hours. On Wednesday the vehicle ran the journey of 21¾ miles without a stop in 2 hours 17 minutes, the average speed being 8·8 miles per hour. On Thursday the car accomplished 29¼ miles in 3 hours 31 minutes, the only difficulty being Orpington Hill, up which the car was pushed for two minutes. The average speed on this journey was 8·3 miles per hour. On Friday 14¾ miles were covered in 2 hours 3 minutes, at an average speed of 7·2 miles per hour. The Canadian Electric Motor Company, of 5, Chapel-court, Long-acre, entered a Still Motor Company's car for four persons, fitted with the "Ideal" battery and Still Motor Company's motor. On Tuesday this car travelled 23 miles in 1 hour 39 minutes, the average speed being 13·94 miles per hour. Towards the end of the run the cells were nearly exhausted, and the passengers had to alight on all hills. On Wednesday no stops were made, and a distance of 21¾ miles was covered in 1 hour 56 minutes at an average speed of 11·25 miles per hour. On Thursday the distance of 29¼ miles took 3 hours 22 minutes, the average speed being 8·68 miles per hour. On this journey two passengers had to alight on the two hills at Orpington. On Friday the distance covered was 20 miles, which was accomplished in 2 hours 22 minutes, the average speed being 8·4 miles per hour. On this journey there were one or two little faults with the machinery.

The Electrical Undertakings, Limited, 12, Miller-street, Camden Town, N.W., had entered one car for three or four persons, fitted with a Leitner battery and Lundell motor. On Tuesday this car covered a distance of 33½ miles in 4 hours 26 minutes, the average speed being 7·5 miles per hour. On Wednesday the distance of 21¾ miles was, as in most of the other cases, accomplished without a stop. The time taken on the journey was 2 hours 33 minutes, the average speed being 8·5 miles per hour. On Thursday a distance of 29¼ miles was covered in 3 hours 50 minutes, the average speed being 7·63 miles per hour. On Friday a run taking 4 hours 50 minutes was made, the distance being 35¾ miles, and the average speed 7·4 miles per hour. The observer in this case remarks that he walked 1½ miles home.

THE FACTORS WHICH DETERMINE THE DESIGN OF MONOPHASE AND POLYPHASE GENERATORS.*

BY B. A. BEHREND.

(Continued from page 671.)

To enable the reader to judge for himself as to the correctness of the method here employed, other series of tests may be adduced. The Curves I. and II. in Fig. 4 represent the static and short-circuit characteristics of a

27·5	7,830	75	3,910	3,870	38

Table II. contains side by side the results of the tests and the calculated values of the voltage at the terminals. The

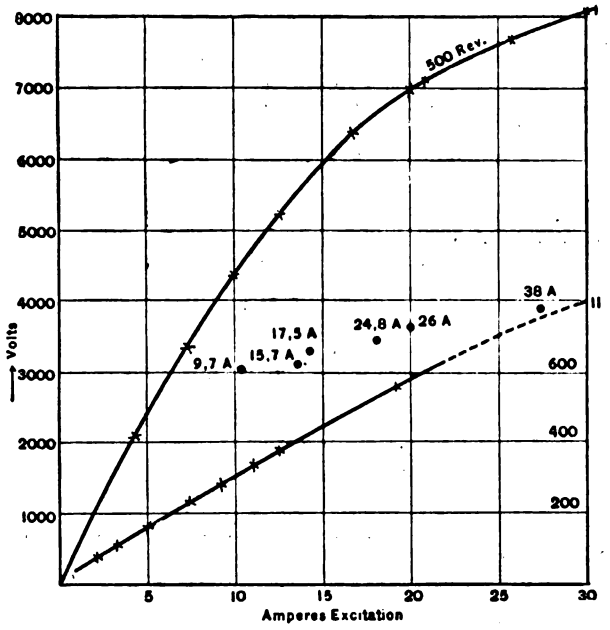

FIG. 4.—Static and Short-Circuit Characteristics of Three-Phase Inductor Generator.

symbols at the heads of the columns are the same that were used in the preceding table. The load of the generator consisted of wattless current This current is given in the sixth column of the table. The agreement is again good, especially if we take into consideration the difficulties connected with the measurement of such high voltages. Fig. 5 represents the characteristic of a 450-h.p. three-phase current generator of the inductor type. Number of revolutions per minute 600, frequency 60, voltage 6,700 between the lines. Pole-pitch, 33cm. The generator was loaded with a synchronous motor, and the following data were observed :

Generator.—530 revolutions per minute, 6,000 volts, 30 amperes, 34·5 amperes excitation. To this excitation correspond 97 amperes short-circuit current and 9,830 volts on open circuit at 600 revolutions per minute.

TABLE III.

Generator.				Motor.

45	192	221	3,500	179·7	20·3	157	2,370	139

Synchronous Motor.—Excitation of the synchronous motor, 11·8 amperes. The synchronous motor as a generator developed with this excitation 55 amperes on short-circuit and 3,900 volts on open circuit.

With these data we find : (1) The terminal voltage of the generator ought to be, if the 30 amperes consist of wattless current, $9,830 - 30/97 \times 9,830 = 6,760$ volts at 600 revolutions per minute. Reduced to 530 revolutions per minute we get $530/600 \times 6,760 = 5,970$ volts, instead of 6,000 volts as observed. (2) If we start our calculation from the synchronous motor, the terminal voltage ought to be $3,900 + 30/55 \times 3,900 = 6,030$ volts. The three tests described above were made on inductive generators. The following data are from a very comprehensive series of observations on a generator with alternating poles. Two dynamos with four external poles and revolving armature in star connection were used for the tests. One machine was run as a generator, the other as a synchronous motor. The pole-pitch was 77cm., the air-gap 1·3cm. The ratio of width of pole to pitch of pole was 0·60. In a design

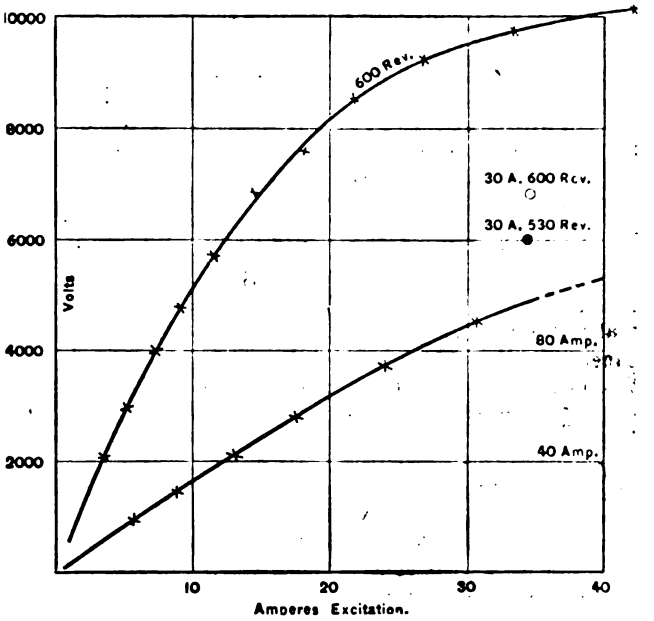

FIG. 5.—Characteristics of Three-Phase Inductor Generator.

like this the leakage is naturally very small. This is manifested by the low value of the ratio of the ampere-turns in the field to the ampere-turns in the armature, which ratio was 2·30. The number of revolutions per minute was 470, the frequency 15·7 periods per second. The voltage of this machine was 180 volts, the current in each phase 650 amperes, corresponding to an output of 200-kilo-volt-amperes. The accompanying table and Fig. 6 contain the results of the observations. The current between generator and motor was 655 amperes. Generator and motor being exactly alike, the much smaller excitation of the synchronous motor and the large current flowing between the two machines insured a power factor which did at all events not exceed 0·20. The terminal voltage of the generator is calculated as in the preceding examples. The

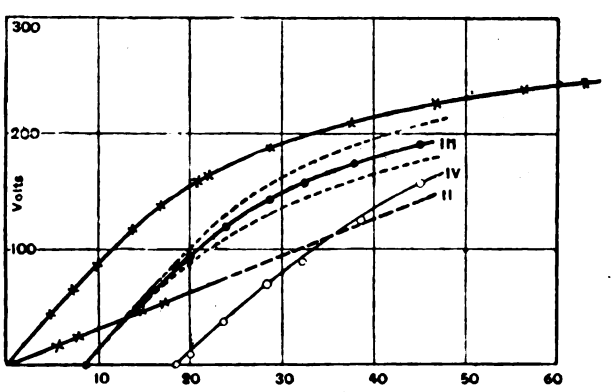

FIG. 6.—Curves relating to Test of Generator with Alternating Poles.

E.M.F. of the motor is computed from the terminal voltage and the short-circuit current belonging to an excitation which corresponds, not to the E.M.F., but to the terminal volts—that is to say, to that excitation of the machine which is necessary to produce the terminal voltage on open circuit.

The agreement of calculation and observation is by no

Digitized by Google

means so perfect in this case as in the foregoing examples. This difference is due without doubt to the considerably smaller leakage of these large four-pole dynamos. The armature winding was distributed over the surface of the armature in 216 open slots, thus greatly diminishing the self-inductance of the armature. The pole-pitch of 77cm. is much larger than usual, thus in its turn diminishing the leakage.

Curve I., Fig. 6, represents the static characteristic, equal in generator and motor. Curve II. is the short-circuit characteristic, also equal in the two machines. Curve III. is the dynamic characteristic for 655 amperes wattless current. Curve IV. is the E M F. of the synchronous motor, taken from its static characteristic by means of the values of the observed exciting current. This curve demonstrates that the current must have been practically in quadrature with the E M.F.'s and the terminal voltage. The broken line curve below Curve III. represents the values of the terminal voltage, calculated according to the method employed in this paper. The broken line curve above Curve III. represents the terminal voltage calculated by simply deducting the armature ampere-turns from the field ampere-turns.

This case is very instructive. First, it shows that neither method is theoretically correct. Secondly, it teaches us that the method which has been employed all through this paper may give values of the terminal voltage lower than those observed. Though this is certainly no advantage of the method, neither from the standpoint of the theorist nor from that of the designing engineer, yet it will be a "safe" method. The designer who is conversant with these facts knows beforehand that the terminal voltage, as determined in this manner, will surely be the lowest possible value. Some experience will soon teach him in what case he may expect a drop approaching the calculated one, and in what case the drop is likely to be smaller than he expected. The difference between the calculated and the observed values of the terminal voltage does not exceed, even in this case, 8 4 per cent. of the actual value. If, on the other hand, the designer relied on the method of the addition or subtraction of the ampere-turns of the armature and the field—treating them, of course, as vectors—he would attain results which might induce him to proportion insufficiently the magnetic circuit and the field coils.

It would be useless to here multiply the examples, as every electrical engineer can convince himself of the correctness, within wide limits, of this method.

As the drop is due to the combined effect of (1) the leakage of the field; (2) the reaction of the armature; and (3) the leakage of the armature, a satisfactory theory must account for each of these factors. Our method of determining the combined effect of these three factors from the short-circuit curve and the static characteristic does not do this. It can, therefore, not properly be called a theory. If, indeed, it were possible to design a generator without field leakage and without armature leakage, the method here adopted would give unsatisfactory results; but at present the best alternators have considerable stray fields, large enough to justify the application of the method here advocated for practical purposes.

Space does not permit me to discuss in detail the influence of the three factors mentioned above. Viewed from the practical standpoint, the question turns mainly on the avoidance of leakage. Now, the leakage in the field as well as in the armature can be diminished considerably by enlarging the pole-pitch—that is to say, by placing the poles apart as far as is compatible with an economical design. We shall dwell on this point in the third part of this article.

From the foregoing the reader will have gained the impression that if it were possible to predetermine the short-circuit characteristic of an alternator in such a manner as to take all important factors into account, we should have at our disposal a simple method which would enable us to calculate the dimensions of alternators with an exactness which would more than suffice for all practical purposes. I shall show in the following section how this may be done.

(To be continued.)

FATALITY AT THE METROPOLITAN ELECTRIC SUPPLY COMPANY'S WORKS.

On Thursday Dr. George Danford Thomas, coroner for Central London, held an enquiry at the Marylebone Coroner's Court into the circumstances attending the death of Rowland Herbert Pickworth, aged 22, an electrical engineer's assistant, lately living at 73, Park-road, Marylebone, who died from an electric shock whilst at work at the Metropolitan Electric Supply Company's works at South-street, Marylebone, on Tuesday morning last.

Mr. Gil Blenkinsopp (her Majesty's inspector of factories) watched the case on behalf of the Home Office.

Mr. REUBEN PICKWORTH, of independent means, residing at Dyke-road, Brighton, stated that the deceased, his son, had been in the employ of the Metropolitan Electric Supply Company as assistant electrical engineer at their works in South-street, Marylebone, for 18 months, and he enjoyed excellent health. On Tuesday morning he received a telegram informing him of the death of the deceased, and he afterwards heard that the deceased was attending the switchboard at the works when by some means his hands came into contact with a live conductor, which caused instant death.

GUY BRANDEN, a switchboard attendant in the employ of the Metropolitan Electric Supply Company, stated, in answer to questions by the Coroner, that men engaged at the works were instructed as to their duties and what precautions were necessary. Gloves were provided for use in the work. On Tuesday morning at seven o'clock witness went to the works and found the deceased there. At half-past eight he saw the deceased engaged in the connecting some large cables, and these had to be connected with a switch. He turned round and saw the deceased falling, and he then noticed that deceased had received a shock, he evidently having, instead of taking hold of the insulated handle of the switch, taken hold of the metal work with both hands, the result being that the current had passed through him. He went and pulled him away by taking hold of his coat. Means were at once used to restore him, but without avail; and on a doctor being called it was found that he was dead.

ARTHUR WYATT, superintendent of the South-street station, stated that the deceased had been an assistant for 18 months, and he was well acquainted with the duties and regulations with regard to what precautions were necessary to be taken for safety. There was at the works a large switchboard requiring certain connections made to it. The connections could have been made with perfect safety had the deceased taken hold of the insulated handle provided. The switchboard itself was insulated. Had deceased looked above his head, he would have seen whether the current was on or not by the pilot lamp. At the time of the accident the line voltage was 1,000.

Mr. REGINALD TODD, chief engineer to the company, said that the ordinary precautions were taken for the safety of those engaged at the works, and to enable anyone to see whether the current was on a switch, there was a pilot lamp above it, which a person could at once see by looking up, and it was evident that in this instance deceased took hold of the switch by the metal portion with both hands, thinking the current was off. He should consider whether it was not possible for some method to be adopted by which a similar accident to this would be avoided in the future.

The CORONER said that there was no doubt from the evidence that the deceased must have forgotten that the switch was charged when he took hold of it. He should not advise the jury to recommend in their verdict any particular kind of protection to be taken, because it might be that they as laymen might recommend something that might be unsuitable. They had better leave it to the company to find out what were the best methods to adopt.

The jury returned a verdict that the deceased died from the effects of shock from electricity arising at a time when the deceased's hands came in contact with the metal of a live switch, and that death arose from accidental causes. The jurors would recommend to the immediate consideration of the company the necessity of protecting the metal switches in such a manner that a similar occurrence could not happen again.

LIGHT RAILWAYS.

A meeting was held recently in Lyndhurst to discuss the proposal to have an electric railway from Lyndhurst Road to Lyndhurst.

The Commissioners have confirmed (1) an order for light railways in the borough of Dewsbury, the urban districts of Cleckheaton, Liversedge, Heckmondwike, Gomersal, Birkenshaw, Huntsworth, and Thornhill, and, under certain conditions, in the city of Bradford and the borough of Batley, in

Digitized by Google

the West Riding of the county of York; and (2) an order entitled the Gosforth and Ponteland Light Railway Order, 1900, authorising the construction of a light railway in the county of Northumberland between Gosforth and Ponteland.

The negotiations between the North-Eastern Railway Company and the directors of the Goole and Marshland and the Isle of Axholme light railways have resulted in an agreement on the part of the North-Eastern to purchase the two light railways and work the lines. The company are also about to ask for parliamentary sanction to put into force the powers which the Light Railway Commissioners have granted for the construction of a light railway from Haxey to Tickhill, which will thus give the North-Eastern direct access to the Derbyshire coalfield.

The Board of Trade have recently confirmed the undermentioned light railway orders: (1) Bourne Valley Light Railway Order, 1900, authorising the construction of a light railway in the county of Southampton from Whitchurch and Hurstbourne Stations to Vernhams Dean; (2) Bishop's Waltham Light Railway Order, 1900, authorising the construction of a light railway in the county of Southampton from Bishop's Waltham to a junction with the authorised Meon Valley railway near Brook Bridge, in the parish of Soberton; and (3) the Derby to Ashbourn light railway.

The Commissioners have issued the draft of an order they propose to make authorising the construction of the Darlington light railways.

FORTHCOMING EVENTS.

FRIDAY, NOV. 16.

Institution of Mechanical Engineers.—At 8 p.m., ordinary general meeting. Paper on "Capacity of Railway Wagons as affecting Cost of Transport," by Mr. J. D. Twinberrow.

Electro-Harmonic Society.—At 8 p.m., at St. James's Hall Restaurant, evening concert (ladies' night), Major Crompton presiding.

North-East Coast Institution of Engineers and Shipbuilders.—At Sunderland, ordinary meeting. Discussion on Mr. C. H. Innes's paper on "The Stress produced in a Connecting Rod by its Motion," and a paper on "Liquid Fuel," by Mr. E. L. Orde.

SATURDAY, NOV. 17.

Glasgow and West of Scotland Technical College Scientific Society.—At 7 30 p.m., ordinary meeting. Paper on "Some Notes on the Organisation of a Workshop," by Mr. H. D. Jackson.

North-East Coast Institution of Engineers and Shipbuilders.—At Newcastle, graduates' meeting. Paper on "Comparison between British and American Locomotive Practice," by Mr. H. J. Potts.

MONDAY, NOV. 19.

Imperial Institute.—At 8.30 p.m., free lecture on "The Coal Resources of Victoria," by Mr. Jas. Stirling.

TUESDAY, NOV. 20.

Institution of Civil Engineers.—At 8 p.m., ordinary meeting. Discussion on paper on "The Metropolitan Terminus of the Great Central Railway," by Messrs. G. A. Hobson and E. Wragge; and, time permitting, paper on "Machinery for the Manufacture of Smokeless Powder," by Mr. Oscar Guttmann.

WEDNESDAY, NOV. 21.

Society of Arts.—At 8 p.m., ordinary meeting. Opening address of the 147th session, by Sir John Evans, K.C.B., F.R.S., chairman.

Royal Meteorological Society.—At 7.30 p.m., at Institution of Civil Engineers, ordinary meeting. Paper on "An Improved Mounting for the Lens and Bowl of the Campbell-Stokes Sunshine Recorder," by Mr. Richard H. Curtis.

THURSDAY, NOV. 22.

Institution of Electrical Engineers.—At 8 p.m., ordinary meeting. Paper on "Telegraphs and Telephones at the Paris Exhibition," by Mr. J. Gavey.

Institution of Electrical Engineers (Dublin Section).—At rooms of Royal Dublin Society, first ordinary meeting.

FRIDAY, NOV. 23.

Physical Society.—At 5 p.m., ordinary meeting. Papers on "The Anomalous Dispersion of Carbon," by Prof. R. W. Wood; "The Liquefaction of Hydrogen," by Mr. M. W. Travers; and "On the Refraction of Sound by Wind," by Dr. E. H. Barton.

Institution of Junior Engineers.—At 7.30 p.m., joint meeting with the Architectural Association at 9, Conduit-street. Paper on "The Uses of Rolled Joists in Construction," by Mr. A. T. Walmesley.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

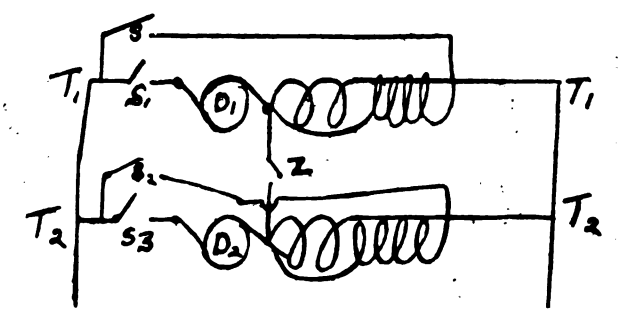
325. While in charge of the controlling board in a high-tension alternating-current station, the shift engineer switched in a machine without synchronising it with another machine on the 'bus bars. The former machine was high-speed—150 amperes at 2,000 volts; the latter being a low-speed—50 amperes at 2,000 volts. After the two machines were connected there was a drop of five volts on the low-tension voltmeter, and although I took all the resistance out of the shunts the voltage slowly dropped, until the light entirely faded out. Then the fuses of the low-speed machine became white hot and blew. Kindly explain the reason for the above.—A. H.

326. Describe and explain some method of determining the hysteresis loss in the armature of a continuous-current dynamo.—R. F. W.

ANSWERS.

Question No. 319.—Why is it not common to run compound dynamos with equalising cables connecting all the series coils in parallel on town-lighting supply? Would not this be advantageous where many heavy motors were coupled to the lighting mains? Give reasons for and against.

Best Answer to No. 319 *(awarded* 10*s.).*—To understand why compound machines are not used to any great extent in central-station work, a study of the working of these machines will be an advantage. The great convenience of compound-wound machines is that in a single machine the series-turns can be made to compensate for the drop in pressure between the dynamo and outside circuit. When compound-wound dynamos are run in parallel this effect cannot be produced, as the rise in pressure is caused by the individual machines, not the sum. To run compound machines in parallel two series windings would be required on each machine, one winding carrying the output of the machine alone and balancing the action of the machine itself—that is, the fall in voltage—and the other to effect the over-compounding, and thereby balance the drop in the feeder and distribution system—that is, this second winding carries the whole output of the station. This means complicating the field windings, and although a steadier pressure is obtained on the mains, especially in the case mentioned, it is not worth the extra cost which the winding would involve.



Another point against using machines as suggested is the fact that a somewhat complicated switching arrangement would have to be carefully followed out, or a serious accident would be likely to follow. Now, using shunt machines the magnets are excited from the mains, the machine is speeded up to the required voltage, and then

Digitized by Google

switched in. This is a simple process, but in running compound-wound machines in parallel the following method of putting a machine in circuit must be followed: Now suppose machine D_1 is running and D_2 is required to take up some of the load. Switch S_1 connecting on to the mains and S connecting the shunt will be on. To put D_2 in circuit, D_2 is speeded up and the shunt switch S_2 closed, exciting the field. Switch Z is then closed, and when voltage is right main switch S_3 is closed, putting machine in circuit. This sounds easily accomplished, but when the switches are on the board surrounded by others a mistake may easily occur. It is far better plan to use shunt machines and a booster to keep the voltage steady.—F. M. M.

Answer to No. 319 (*awarded* 5s.).—Practically the whole of the continuous-current stations installed during recent years have taken advantage of the copper economy afforded, and adopted the three-wire system, so that it is in conjunction with this system that the comparison between compound and shunt machines must be made.

Let us first consider the principal points of the system generally employed. Shunt machines are used in most stations connected across the outers, in conjunction with a relatively small balancing set, with the middle point between the two armatures connected to the middle wire. A battery also is generally installed, and this materially helps to balance the system, besides supplying a reserve of power at heavy loads, enabling the machines to be run at or near their most efficient point. If a small differential booster is connected in series with the battery, it is enabled more readily to give out power with a diminished drop in voltage at the battery terminals, and thus to aid the main machines; so that, if the size of the battery and booster are suitable, the volts at the station need not vary to any great extent, although it will be necessary to rise the pressure at the station in times of heavy load, so as to allow for the drop in potential up to the feeding points, which of course varies with the current in the feeder.

Now, if we are to adopt compound machines instead of shunt, still using the batteries, we need to see substantial reasons for so doing, as the machines themselves will be of higher cost. The main machine cables leading to the switchboard will need to be practically of double length (owing to the necessity of first connecting to the balancing 'bus bar and then back again to the series winding), and the switching arrangements will be somewhat more complex and expensive. If by their use we are enabled to obtain a constant voltage at the *feeding points* at all loads automatically, the extra outlay might be advisable. Let us see if this can be done. It is evident that to effect this the machines must be over-compounded, and in the event of a heavy load the station voltage will in consequence be raised above the normal. Now, if batteries are connected across the station mains, without any booster in circuit, they will at once commence to charge, or, at any rate, will reduce the amount of power they were formerly giving out to the circuit. Thus, when most needed as a help, they would prove a hindrance. But, to place the two systems under comparison on the same footing, let us assume that differential boosters are in circuit with the batteries, and are so designed that they will supplement the battery voltage sufficiently to enable the battery to give out an increased current with the increased load (they must be of larger range to do this than in the case of the shunt machine); difficulties still occur. The generators will, if properly compounded, compensate for the voltage drop in the feeders, provided the *whole* current can pass round the series coils, but with the battery supplying current for varying amount this is obviously impossible, so that the voltage could not be kept constant at the feeding points automatically, and if the services of the switchman are required to effect this object, why not employ the cheaper shunt system.

Apart from this, over-compounded machines are not considered suitable for employing with batteries, owing to the fact that any reverse current through the machine weakens the strength of the field magnets, instead of (as in the shunt machines) strengthening it, and this further reduces the voltage of the generator and renders it liable to a reversal of polarity. The shunt system therefore, in spite of its lower cost, seems preferable, if batteries are used in both cases. Let us deal with the case where compound machines are used without batteries, as compared to shunt machines with them. The whole load will now fall upon the generators, which, in consequence, must be of sufficient power to cope with the highest peak of the load curve, and this in some districts would render a considerable addition to the present plant necessary. The machines also, in times of comparatively light load (especially if a large part of that load consists of motors), must be run considerably under their full output, otherwise, although the series coils might endeavour to keep up the voltage in the event of a sudden addition to the load, the machines will slow up, and thus cause a drop in volts, to say nothing of the danger arising from overloading the machines. Under these circumstances, the efficiency of the plant will be decreased.

Again, the battery plays a most important part in the balancing of the system, and if it is dispensed with, having a larger balancing set will only partially compensate for the loss. In small stations also it is found to be a great advantage to be able to shut down the running plant at night, and to feed the mains entirely from the batteries, for by so doing a third shift is dispensed with, and as a large number of continuous-current stations avail themselves of this, it must be reckoned as a point against the employment of compound machines without batteries.

In conclusion, I think that although compound machines are undoubtedly beneficial for many purposes, yet for general distribution from a generating station, shunt machines, having a differential booster in series with the battery, have decided advantages, even though the proportion of motor load be comparatively large.—W. G. M.

Answer to No. 319 (*awarded* 5s.).—Though compound dynamos offer certain advantages for stations in which large and sudden variations occur, such as traction stations, they are not to be recommended for the ordinary lighting station. Even if the station supply a large amount of current for power purposes, it is most unusual for the general momentary load variation on the motors to be sufficiently large in themselves to affect the 'bus bar voltage. Further, the rules of most supply companies provide against a sudden rush of current when starting a motor by insisting on a certain small current (10 to 50 amperes) not being exceeded when the starting switch is on its first contact and the motor is at rest. This being the case, shunt dynamos regulated by hand are found quite satisfactory, though compound dynamos would undoubtedly require less attention in this respect. The latter would, therefore, probably come into more general use if it were not for the practical difficulties in running them in parallel. In spite of the use of an equalising lead putting the series windings of all the machines into parallel, there is distinctly more tendency to disproportionate loading with compound than with shunt dynamos. The reason is that if from any cause, such as a rise in speed, one of the dynamos give more than its proper proportion of load, the armature reaction will immediately lower the volts of a shunt machine, which thus tends to right itself, whilst in the case of a compound dynamo, though there is a certain amount of self-righting effect (due to part of the excess current being diverted from the series winding of the overloaded machine to those of the other machines by the equalising lead), it is much smaller than in the shunt machine. The result is that a given rise in speed on one of the machines produces a much greater overloading of that machine if it is compound than if it is shunt wound. Any advantage on the side of the compound dynamo in the way of self-regulation is further discounted when it is remembered that even if the machine is wound to compound exactly level when warm, it will compound down to an appreciable extent when cold at first starting up. On this account a resistance in the shunt for hand regulation is still a necessity, almost as much as in the case of the shunt machine.

The advantages and disadvantages of a compound dynamo may, then, be shortly stated as follows:

Advantages.—(1) They serve to maintain the supply voltage more steady under large and sudden load variations,

Digitized by Google

when these occur; (2) they require little or no hand regulation as the load increases.

Disadvantages.—(1) Practical experience has shown that there is more liability to disproportionate loading of the various machines in parallel due to unavoidable speed variations; (2) though the characteristic curve may be level at a given temperature of the field coils, its shape is sure to change when they are either cooler or hotter than this, and hand regulation must then be resorted to, just as in the case of the shunt machine; (3) the shapes of the characteristic curves of the different machines in parallel must closely resemble one another for satisfactory work, and this condition, as well as the condition that the resistances of the series windings should be in inverse proportion to the outputs of the respective machine, are often difficult to fulfil when installing new machines of various makes.—Q.

Answer to No. 319 *(awarded* 5*s.).*—The reason compound-wound dynamos have not come into general use in electric lighting stations appears to be due to one or more of the following disadvantages; (*a*) complication of switch gear; (*b*) greater liability to accidents when changing the machines about; (*c*) extra cost.

Referring to (*a*) it will only be necessary to carefully examine the connections involved, when, say, a set of six machines are required to be run in parallel, in order to see the extra switch gear required over and above that used for simple shunt machines, and also the fact that this requires very careful manipulation, or very serious things will happen. Should a breakdown occur at one of the engines a very serious short-circuit would result unless the automatic cut-out came out to time, and in some cases reversal of polarity has resulted from the series coil overpowering that of the shunt due to the latter failing or the engine failing. In the case of the shunt machine it is not possible to reverse the polarity should the engine fail, because the direction of the current round the field coils of a shunt machine is the same when giving out current or receiving current as a motor, so that should the pressure of the shunt machine fall a little below that of the rest in parallel with it the machine would tend to draw the engine round; but with the compound dynamos the case is very different, as pointed out above, for should this reversal of current round the series coil overpower the shunt a reversal of polarity follows, and unless careful precaution is taken a consequent short-circuiting of the rest of the machines, hence a very reliable zero cut-out must be used.

From the point of view (*b*) it may be well said that the compound machine is not so easily handled as the shunt machine, and simplicity is everything in central-station working, especially where a great number of units are already installed; and I think it may be said that if the shunt machine is well designed, and fitted with a good field control, and the machine coupled to an engine having good expansion gear or simply a reliable throttle governor, that for a general lighting supply it is all that is required, without going to extra expense and complication.

Dealing with the latter part of the question, there is no doubt that the use of compound machines on a supply having a good number of heavy motors would be helpful, especially if these are constantly varying in load. Then the compound machine can better deal with this class of supply, which brings us practically down to the tramway supply, for which the latter machines are best suited, but, generally speaking, the average station's motor load is small, and not of so varying a nature as that of a traction station. In one or two larger stations I believe compound machines are used on a lighting supply, but it is only in one or two instances, and no doubt the loads are subject to great variation in these particular stations—as in Glasgow, for instance.

In cases of combined lighting and traction stations the modern practice tends towards the employment of compound dynamos, with a switchboard arranged for each source of supply, so that the generators may be used on either lighting circuit or tramway supply, but in most cases the dynamos are so arranged that when the leads are plugged up to the lighting mains the field series coils are cut out, leaving the machine to do duty as a simple shunt machine.—A. H.

Question No. 320.—In an alternate-current station where accumulators are charged by means of a direct-current dynamo driven by a synchronous alternate-current motor, what will be the increase in the cost per unit supplied due to the conversion and storage of the electrical energy and to capital charges on the additional plant?

Best Answer to No. 320 *(awarded* 10*s.).*—The increase of cost per converted unit will very greatly depend upon the number of units so converted, upon the maximum demand at any one time, and upon several points on which no data are furnished. The question may, however, be investigated in general terms, and an expression obtained from which the actual increase of cost may readily be found.

Let p = cost of each alternating unit;
H = price of alternating motor and continuous-current generator;
B = price of battery and accessories;
η = efficiency of combined motor and generator;
ζ = efficiency of battery under average conditions;
α = rate of interest per cent. on capital sunk;
β = allowance per cent. for depreciation of machinery;
γ = allowance per cent. for depreciation of battery;
C = annual extra expense for attendance, oil, etc.;
N = number of units converted per annum.

Then the cost of each converted unit is

$$\frac{10{,}000\,p}{\eta \times \zeta} + \frac{\alpha\,(B + H) + \beta H + \gamma B}{100\,N} + \frac{C}{N}.$$

The extra cost thus consists of three parts: (1) making up the loss of energy in converting; (2) covering interest and depreciation; (3) covering extra attendance and expense. As an example in the application of this expression, let the case of a converting plant and battery for 500 ampere-hours be considered. The accumulators will cost about £220, the machinery, supposing conditions permit of 10 hours for charging, would probably be about £120; the combined efficiency of motor and generator we may take as 80 per cent. That of the battery depends largely on the rate of discharge, but may here be taken as 85 per cent.; allowance for depreciation of machinery would be 10 per cent., that for the battery nearer 20 per cent.; the rate of interest is taken as 3 per cent.; extra attendance, etc., amount, say, to £80 per annum. Now, if 175 units be converted in the year, and the cost of producing the alternating unit is 1·5d., the cost per converted unit is

$$\frac{10{,}000 \times 1\,5}{85 \times 80} + \frac{3\,(340) + 10\,(120) + 20\,(220)}{100 \times 175} + \frac{80}{175},$$

which comes out to 2·805d. It will be noted that the greater part of the extra cost is due to the loss of energy in conversion. The exact proportion, however, in which it comes under each of the three terms depends upon capacity, maximum current, etc.—ZERO.

SHEFFIELD CORPORATION ELECTRIC SUPPLY DEPARTMENT.

The following is the report on Continental electrical machinery, by Mr. S. E. Fedden, chief engineer and manager of the Sheffield electric supply department, to the chairman and members of the Electric Light Committee of the Sheffield Corporation:

GENTLEMEN,—In response to your instructions, I visited France and Germany in order to gain information with regard to Continental practice in single-phase and polyphase alternating systems, and have pleasure herewith in reporting on my observations. Before starting on the Continent, I obtained introductions and pass-cards for permission to visit the electricity works, and I must take this opportunity to thank Mr. Robert Hammond for his kind assistance in this direction. The firms through whom I obtained these permissions had, in addition to exhibits at the Paris Exhibition, carried out the complete contracts for the several stations which I visited, and I received every courtesy and assistance in obtaining information from their representatives.

The city of Paris, as London, is divided into numerous districts, and supplied by different companies; some supply

Digitized by Google

continuous current and some alternating. The stations in the city, however, very soon became loaded up, and it was then found necessary to go outside Paris and generate electric energy on a large scale. A big station was therefore erected about six miles down the River Seine, and I was informed that they already had 12,000 h.p. of polyphase machinery, working at 3,500 volts, installed. So strict were they, however, about admitting anyone into the station that I was not allowed in, although I took a letter of introduction from a prominent consulting engineer in Paris to the manager, who was a personal friend of his. At the Exhibition I had very great difficulty in getting about, as on the four days I was there the President was entertaining the mayors of the whole country, and as a consequence there were half a million of people in the Exhibition. However, I saw a large number of very fine engines and alternators, more especially in the German section. The Germans have made a very great advance in all electrical machinery during the past few years, and, as a rule, the design of the five large manufacturing firms is very similar. It is also similar to American practice, but the finish on the work of the German machinery is far superior to that of the American. There were three large vertical engines in the German group—combined triple-expansion three-cylinder and triple-expansion four-cylinder. These engines were 1,500 h.p., 2,000 h.p., and 2,500 h.p. respectively. One was direct-coupled to a polyphase 2,200-volt generator by Siemens and Halske. The next engine was built by the Consolidated Augsburg and Nuremburg Company, giving an output of 2,000 h.p. at 83 revolutions per minute. The Augsburg Company make a speciality of horizontal engines, whilst the Nuremburg Company have built more of the vertical type. On one of the Augsburg engines was connected a 1,060-kw. Helios alternator of very fine design, running at 70 revolutions per minute, and furnishing either polyphase or single-phase current. The French company (Anciens Etablissements Cail) had a large vertical compound Reynold-Corliss engine coupled to three-phase 5,500-volt alternator of the French Thomson-Houston Company. The French company also had numerous other steam alternators of varying power from 1,000 h.p. to 2,000 h.p., connected mostly to polyphase alternators. The ruling periodicity is 50 per second, although some companies vary a few periods either one side or the other from this. (You will, no doubt, remember that this is the periodicity which it was decided our new machinery should be constructed for and our present machinery be lowered to.) The alternators are insulated for any voltage that may be required, according to the distance of transmission, and are direct-coupled to the engines. The speeds are all low, from 80 to 125 revolutions per minute. The largest polyphase alternators on exhibition had been manufactured by the Allgemeine Elektricitats-Gesellschaft. This was 3,000 kw. The engine, however, had not been completed in time for the Exhibition, therefore a motor had been connected up to show it running round. I saw polyphase motors at work for all purposes, from ¼ h.p. up to 135 h.p. Alternating motors were also working spinning and printing machinery, cranes, elevators, and the moving staircases, and, in fact, almost everything imaginable where clean and easily accessible power might be required. One polyphase motor of 125 b.h.p. takes its energy direct from the mains at 3,500 volts, and is belted to the centrifugal pump for supplying the water to all the fountains round the Trocadero building. It was working under most exceptionally trying conditions on account of the wet place in which it was erected, but the attendant informed me that it went along regularly almost day and night, and no trouble had been experienced on account of the high voltage or otherwise. The new liquid air machine was also being worked by an electric motor. There were also a few single-phase motors working, but the proportion was small compared with the polyphase.

The Nernst Lamp Company had a very fine display of electric incandescent lighting. This company has a new incandescent lamp which takes only 1·5 watts per candle, as compared with 3·5 to 4 watts per candle used by our present type of lamps. It is a new patent, is at present very costly to make, and the lamps only last from 200 to 300 hours. It, however, gives a very brilliant white light, and as soon as the company are in a position to place it on the market as a reliable article I have no doubt electric lighting will have an enormous boom. The general illumination at the Exhibition is quite beyond description, and it must be seen to be appreciated. It comprises incandescent and acetylene gas, and a most lavish display of arc and incandescent lighting. The electrically-illuminated fountains, at the end of the Champs de Mars, are one of the features of the Exhibition. The Bremer arc lamp is also another improvement in arc lighting, and a decided advance both in the cost and power for street-lighting may be expected if the experiments now being carried out by Herr Bremer fulfil his expectations. The carbons are prepared with 20 to 50 per cent. of non-conducting salts of metals, such as calcium, silicon, and magnesia, and experiments at present show that by this new method light can be generated at an expenditure of about ·1 watt per candle, as against ·4 to ·5 watt per candle as is at present the practice. The new lamp, therefore, is three times as efficient as the best of the old ones, and I was informed that the regulating mechanism was exceedingly simple, but the details have not yet been disclosed. The reason why this lamp gives so much more light than our present arc lamp is that the arc itself furnishes considerable light, and so makes a more even distribution of illumination, whereas in the present ordinary lamps most of the illumination comes from the glowing carbons. I have considerable hopes of this lamp, and trust that it will be placed upon the market in a practical form in time to be considered when the question of the arc lighting of the streets of Sheffield is gone into. The street arc lighting in Paris is not very good, because the arcs have been surrounded with very small globes. Each lamp has its own transformers at the foot of the pole to transform the alternating current from 3,000 volts to 35 volts; and, on enquiry from the lamp-trimmers, I found that two men attended to 60 lamps per day. I visited the Paris Municipal Buildings, which are most lavishly decorated, and there observed that the incandescent gas lighting, which had been installed on a very elaborate scale, was being replaced by the electric light.

Strassburg (Population, 150,000).—At Strassburg, the first thing I noticed was a polyphase motor working in the pouring rain, without a cover of any sort over it. It was down by the riverside screening builders' sand and gravel. On enquiry, I found it was not unusual to use these motors wherever they might be required, either on new buildings for working mortar mills, or for lifting the material to practically any height. The man in charge of this motor simply knew how to switch it on and off at meal times, and otherwise took no notice of it. The parks and public gardens at Strassburg are all brilliantly lighted by arc lamps. I visited the electric lighting station, and made the following notes. The plant installed comprised four 900-kw., one 265-kw., and two 280-kw. steam alternators (polyphase), 3,000 volts; two 600-kw. and two 300-kw. steam dynamos for tramways, continuous current, 500 volts; two 200 and one 400 ampere polyphase motor-driven exciters, 70 volts; one 200-ampere steam-engine exciter. A large set of accumulators are also installed as a stand-by for the tramways, and also for exciting the alternators in case of breakdown of the mechanical exciters. Compressed air is laid on throughout the station for cleaning the running machinery, and the Westinghouse air-compressor is run by a motor. One of the boilers is fitted with a new kind of automatic stoker, similar to the Bennis stoker now in use at the Sheffield station, except that the shovels are arranged to throw the coal to three different distances in the furnace. There are 170 arc lamps in the streets, of the alternating type, and many hundreds of motors from ¼ h.p. to 100 h.p., one factory alone taking 300 h.p. from 6 a.m. to 6 p.m. This is in a city of only 150,000 people (as stated above). The charge for energy for lighting is between 6d. and 7d. per unit; for power, 2½d. per unit. Coal in Strassburg is very expensive, and the cost per unit at the works, notwithstanding the advantage of the heavy day motor load, came out at 1·43d., which leaves a very small margin for profit on the price of the power when other costs are taken into account. The capital expended in the works came out at about £92 per kilowatt installed, as against about £150 per kilowatt installed in Sheffield. There are numerous other important points of a technical nature with regard to the laying out of the engine-house and the working of the condensers, etc., which I carefully noted.

Nuremburg (Population, 160,000).—At Nuremburg I spent several hours in the factory of the Schuckert Electrical Company, where 8,000 men are employed. These works are divided into two sections, one for the manufacture of continuous and the other of alternating machinery. In the continuous-current section the power for all machines, cranes, lifts, etc., is supplied from its own continuous-current central station, and in the alternating-current section all the power is supplied from its own alternating-current station. This gave me an excellent opportunity of comparing the two systems side by side, and I must confess there was very little to choose between the adaptability and working of the two methods, except that the alternating-current motors could stand very much more rough usage and did not require so much looking after as those run by continuous current. Portable tools, worked by motors, were carried about the shops to all heavy work, instead of moving heavy work to the tools. In each power station was erected a connecting link between the two systems, in the form of a motor-generator and rotary converter, so that if there was not sufficient demand for both sections at night to run the two stations, one only was run, and the alternating current was converted to continuous for the continuous-current shop or *vice versâ*. In these shops I saw much two-phase machinery in the course of construction, and one large generator of special interest, to work direct with 20,000 volts, for a transmission scheme. I thoroughly examined and was much impressed with the satisfactory way in which the work was being executed. From the Schuckert Company I proceeded to the Nuremburg electricity station, and found there installed four 300-kw. steam alternators, 2,000 volts, 125 revolutions per minute, and two 650-kw., 2,000 volts, 94 revolutions per minute. This

Digitized by Google

station is single-phase, alternating, 50 periods. More than half the total load of this station is motors, there being no less than 1,100 h.p. of motors connected to the mains, the majority of which run from 6 a.m. to 6 p.m. The motors vary from ½ h.p. to 50 h.p., and are said to be most satisfactory and to start well. All motors are fitted with properly-designed starting switches. From enquiries I made here, the consumers seem to be very well satisfied with their single-phase motors, and I was further informed that there had been no call for continuous-current motors, as it is found that the single-phase alternating-current motors will do all that is required of them. The Schuckert Company also informed me that they had lately taken out a patent for an automatic cut-in and cut-out switch for all transformers, so as to minimise the light-load losses caused by the continual magnetisation of the transformers. They promised to send me full particulars about this patent switch. I was much struck with the simplicity of the switchboard in the Nuremburg station, and with the ample space—which indeed was a large room behind the switchboard—for bringing in the feeders from the street and also for making connections. I examined the pressure curves to see to what extent this large motor load varied the pressure on the mains, and found that the variation from the normal was very slight, except at 6 a.m., when all the motors were being started up. The price for lighting in Nuremburg is 8d. to 9d. per unit; for power 2½d. per unit, with discounts up to 50 per cent. if the bill amounts to £1,750 per annum. I was informed that the works' cost of coal came out at 1d. per unit. The street-lighting in Nuremburg is excellent, and nearly all the main streets are lighted by alternating arc lamps. The lamps are only of small power (420 watts) and have each their own transformer, as at Strassburg, with a ratio of 2,000 to 110 and choking coil from 110 to 35 volts. I watched these lamps for some time in a great many streets, and did not detect a single flicker or any variation whatever in the light. They are fitted with a big reflector over the arc, and also a large reflecting hood over the globe, which throws down the rays of light which are usually projected upwards by the alternating arc lamps. Half of these lamps are switched out at 11 o'clock at night, and the remaining lamps are ample for illuminating the streets after that hour. The lamp-posts are spaced from 50 to 70 yards apart, and a number of the lamps were suspended in the centre of the street from wires fixed to the houses. This system of lighting a street is very effective, but considerable trouble is experienced in trimming the lamps, especially where there is much traffic, or where there is a trolley wire in existence.

Mannheim (Population, 150,000).—Here I visited the works of Brown, Boveri, and Co., which have lately been erected. There is no steam power of any sort or kind at these works, hence the absence of coal and its attendant dirt. The result is that everything is spotlessly clean. All power is obtained from the town's electricity mains. Overhead travelling cranes are driven by polyphase motors, also all shaftings on which tools are grouped, and, in addition, all isolated machines on which it is advisable to couple a motor direct. The 20-h.p. and 30-h.p. motors were just bolted to the side columns or roofs of the shops, and from here they were belted to the shafting. They therefore took up no floor space, and, on account of their requiring so little attention, it was possible to put them quite out of reach. These motors started up on full load without any sparking on the collector rings, or on the starting resistance. One speciality of this firm's manufacture is that after starting the motors the collector rings are short-circuited, and the brush is lifted. For some years past I have been asked by manufacturers who use steam hammers when it will be practicable to actuate hammers of this class by electric power, and prior to my visit to these works I was unable to answer this question, but I am now able to say that I have actually seen such hammers working by electricity. The hammer itself is worked by compressed air, and on to the compressor is geared a polyphase motor, which is not started up until the man is ready to start using the hammer. When the latter is required, he simply walks over and puts on the switch, and by the time he gets back to the fire and gets out the metal, everything is ready to start hammering. I was told they obtained much finer adjustments with this hammer than that which is obtained when working by steam. Polyphase motors in this workshop were being turned out wholesale (of all sizes), and I saw a very large order for small motors being executed for spinning machines. At the electric generating station at Mannheim I made the following notes: The population is about 150,000, and in the first year they expended £100,000 on their works. There were installed three 1,500-h.p. Sulzer engines, coupled direct to polyphase generators running at 90 revolutions per minute; six boilers with superheaters similar to the Lancashire type made in this country, water purifiers, and a good workshop. The ash arrangements, underneath the boiler-house floor, are most complete, and consequently the boiler-house is entirely free from dirt. The switchboard and the switchroom, behind the board, are of the very latest type, manufactured by the firm of Brown, Boveri, and Co. No high-tension connections of any sort are brought out to the face of the board. All the high-tension cables and connections are in the commodious switch-room, the floor of which is raised on dry wood, and covered with heavy rubber mats. Although this generating station is only a year old, there are already 200 h.p. of motors in small sizes connected to it, besides the works of Brown, Boveri, and Co. There is also at Mannheim a converter station for changing the polyphase current into continuous current. The total capacity of this converter station is over 2,200 h.p., but at present there are only installed three motor-generators of 750 h.p., which supply continuous current to the tramways. The charge for energy is 7d. for lighting and 2½d. for power. At Mannheim I also took particular notice of one or two different types of alternating arc lamps, and find they are now manufacturing them on the Continent so as to run practically noiselessly.

Frankfort (Population, 250,000).—I visited the Frankfort-on-the-Maine electricity supply works. The system here is single-phase alternating current. The capacity of the central station is 9,000 h.p., consisting of four units of 750 h.p. and four units of 1,500 h.p., all direct-coupled to horizontal engines. Besides lighting there is power distribution of about 4,000 h.p. by means of single-phase motors with capacity ranging 1/5 h.p. to 150 h.p. The voltage at this station in the primary mains is 3,000, and at the city pumping station there are three 130-h.p. induction motors, taking their current directly from the mains at 3,000 volts. These pumps work night and day, and supply a section of the city with water. The pumping motors get their current at 1¼d. per unit. These electricity supply works also provide power for the Frankfort tramways. It is converted from alternating to continuous current by motor-generators at a converter station, of ample dimensions, built under a public playground. Its capacity is of 4,700 h.p., and there are at present installed three 750-h.p. motor-generators, all of which are made up of high-tension single-phase alternating-current motors, direct-coupled to the continuous-current dynamos which supply current for the large tramway system in Frankfort. The efficiency of these motor-generators is 90 per cent. There is also installed at this sub-station a large set of accumulators of 276 cells, which will discharge 920 amperes for one hour or 1,800 amperes on emergency for a short time. The charge for energy for the tramway purposes is 1¼d. per unit on the alternating side, or 1½d. per unit on the continuous-current side. Whilst in Frankfort I visited a large warehouse where a single-phase motor elevator was in use. This elevator was used only intermittently, therefore the motor was not kept running continuously. Anyone wishing to use the elevator could start the motor (which was in the basement) from any floor by a starting device patented by Brown, Boveri, and Co. I timed the starting-up of this motor twice, and found it was under 20 seconds before it ran up to speed and automatically synchronised. The elevator was then worked in the ordinary way, and as soon as it was not required further the current was switched off. I was exceedingly impressed with this, and consider that it is practically as good as any continuous-current motor I have seen. I then visited the Pariser Hotel in Frankfort. At this hotel they formerly had a hydraulic elevator worked by steam power, but this has now been discarded and a 10-h.p. single-phase motor put in its place. This motor is used for pumping the water used by the lift to a certain pressure. When the pressure gets to 12 atmospheres the motor automatically cuts out. After the elevator has been used for some time the pressure naturally falls, and as soon as it falls to six atmospheres the motor automatically switches in again, and commences pumping water until the pressure again reaches 12 atmospheres, when the motor again switches itself off. The arrangements for this are most ingenious, as all the starting switches are switched in and out automatically. It is worthy of mention that the space occupied by this motor is about one-tenth of that formerly taken up the engine and boiler. At the Frankfort newspaper office I saw working three 30-h.p. single-phase motors operating printing machinery, one 2-h.p. for a smaller printing machine, and one 3½-h.p. for an electric elevator. So satisfied are the proprietors with the working of these motors that another 30-h.p. is being installed. I then visited the Hotel Fustenhof, where is installed a 25-h.p. single-phase motor-generator for converting the alternating to continuous current. This is used for charging a large set of accumulators during the hours of light load at the station. Customers of this class obtain their current for 1¾d. per unit if they only use their motor-generators during certain hours of the day. If they use them at the time of heavy demand, they are charged the full lighting rates. A patent change-over meter is employed at this hotel, which is arranged to change over from one dial to another at certain hours of the day, so that the accounts can be charged at the different rates by the readings of the different dials. A similar arrangement for storing electrical energy is in vogue at the recreation ground called the Palmengarten, where a very large amount of light is used at night. Here are installed three 25-kw. single-phase motor-generators for converting alternating to continuous current, and a large set of accumulators, and the rates charged are similar to those charged to the above hotel.

Digitized by Google

In this Palmengarten the whole of the grounds are most lavishly lighted with incandescent lights, and also with arc lamps. A band plays in the evenings, and there are 12 lawn-tennis courts. These lawn-tennis courts are banked for flooding in the winter, when they are used for skating purposes. Arc lamps surround the whole of these, so that the people, who here work very long hours, may take their recreation at night by artificial light. The large piece of ground in the Endcliffe Woods would be an ideal spot for making similar arrangements. All the conservatories and museums are brilliantly lighted by electric light, and in the concert-room in this park there are two magnificent electroliers, each containing 20 clusters of nine lamps each. The roof of this building, which is elaborately decorated, is lighted by means of arc lamps, which are hung in four cut-glass wells, and the effect is very beautiful. I was informed upon a number of occasions that the alternating arc lamps were preferred to the continuous current on account of the better diffusion of light. In the Kaiserstrasse, in Frankfort, the arc lamps are placed on the top of the poles which support the span wire for the trolley wire, and the effect of this is that every car passing causes the lamps to jump in succession all the way down the street. The conclusion I came to, therefore, is that it would not be advisable to place arc lamps on any poles which will have vibration from the trolley wire.

Cologne (Population, 290,000).—In Cologne I visited the manufactory of the Helios Company. They kindly showed me round their works, and there I saw a large number of polyphase generators and motors being constructed for all voltages. I also had an opportunity of seeing four different 30-h.p. polyphase motors, which were connected to large tools, stopped and started up on full load. This most conclusively proved to me that these motors are quite as capable of starting on full load as the continuous-current motors. In fact, they started up without any sign of sparking at all with about twice the normal full load current. Two 25-h.p. polyphase motors were also connected to pumps for supplying the boilers with water. I also saw some two-phase motors being built here for 5,000 volts. All the machinery in these works, including the travelling cranes, is worked by polyphase motors. It is this company's practice to wind the rotors—that is, the revolving part of all their motors—whether single, two, or three phase, with three-phase windings, thus making them standard. They then wind the armatures for any phase that may be ordered. I am informed at these works that they still make some continuous-current machinery for moderate sized towns and for repeat orders, but the majority of their new work is polyphase. I inspected the Cologne electricity stations, which are at present single-phase. The old station contains four 600-h.p. steam alternators, and the new station, which is close to the other, now contains two 1,500-h.p. steam alternators. In this new station are also installed separate motor-generators for converting alternating to continuous current, for exciting the alternators, and also a set of accumulators as a stand-by to these exciters. There are about 1,000 h.p. of motors connected to the mains. A very fine switchboard, manufactured by the Helios Company, is in use in the new station. The new project is to place a large polyphase station outside the city, and to convey the current to sub-stations, to be there transformed to continuous current by rotary converters for the tramways, and by static transformers for helping the present supply stations, which will shortly be loaded up. Three hundred alternating arc lamps are connected to the mains of the Helios type, and these lamps give a most excellent light. They are of very simple construction. The railway station at Cologne is lighted off private plant with continuous-current arc lighting; and after comparing the two lamps at night, I came to the conclusion that the alternating arc lamps certainly gave a far superior light to those lighted by continuous current. The two electricity stations at Cologne are unable to run in parallel, on account of the different wave forms of the alternators. One station is, therefore, held as a reserve in case of breakdown in the other. I beg to report that throughout Germany I found that a very large number of small villages, from about 300 inhabitants upwards, are supplied with electric light. All the goods yards at the railway stations are brilliantly lighted by arc lamps. The cattle markets and nearly all the principal markets are also similarly lighted, and in many towns where gas is used in the streets I found, on enquiry, that they are only waiting for the concessions to expire in order to carry out the street-lighting by means of arc lamps. These streets, however, are now well lighted by incandescent mantles of large dimensions.

General Conclusions and Remarks.

The employment of high-pressure alternating currents, preferably of the polyphase type, have given a tremendous impetus to the growth of electrical undertakings for the transmission of power over large areas throughout the Continent. Alternating currents are successfully generated and transmitted at high voltages without the use of step-up transformers, as has been usual in American practice. Alternating currents are now employed for work which a short time ago was considered to be totally impossible. Polyphase machinery is long lived on account of the simple and solid construction of the type of generators and motors. Owing to the great development of high-tension alternating current the switching and controlling gear has been completely remodelled and greatly improved within the last few years, in order to meet the severe demands made upon it, without risk of breakdown or danger to attendants. Polyphase motors will in particular be used in preference to continuous current in mines and foundries, and other places of similar description, on account of the rough treatment and heavy duty which they can withstand, and also because no skilled attendance is required. Polyphase motors are now being used on the Continent for driving jib cranes, travelling cranes, traversers, rolling-mills, turntables, plunger pumps, rotary pumps, centrifugal machines, lifts, and elevators. They are also adapted to all kinds of ventilators, ring spinning frames, weaving looms, and, in fact, almost every type of machinery. I made numerous enquiries at the different factories I visited with regard to the use of two and three phase current, and was informed that they were practically the same as regards efficiency, duty, and starting torque. The old apparent benefit of three-phase over two-phase is in the saving of copper in the mains for long-distance transmission. This is not material in Sheffield, as we already have many miles of mains laid which cannot be suitably converted to the uses of three-phase, but which can be converted to two-phase. There are a large number of installations on the Continent which are most successfully run by two-phase alternators. The largest two-phase induction motor which, I believe, has ever been made is that manufactured by the Brown-Boveri Company. It is 1,000 h.p., taking 5,000 volts direct, and is connected to a centrifugal pump running at 455 revolutions per minute. This set is used at the Geneva Waterworks for pumping water to a height of 460ft. Not the least remarkable feature of this combination is that a centrifugal pump should be employed for throwing water to so great a height. Polyphase traction is now being used on the Continent for a number of mountain railroads, and I quite expect that within a few years it will become general for light railway work. The electricity supply works of the later construction are designed and built sufficiently capacious for the reception of machinery that may be required for some years to come, although this places a rather heavy burden on the starting of a new undertaking. They are generally well designed, spacious, lofty, and well ventilated. The walls are all faced with enamelled brick, and the floors are handsomely tiled. In most cases no pipes of any sort are above ground, ample space being provided underneath the floors for the reception of all steam, exhaust, water, and compressed-air pipes, and all the necessary cables. The condensers are also placed underground. There is also every convenience for the comfort and welfare of the people connected with the undertakings. The chief engineer, his assistant, and the leading hands are usually provided with good house accommodation on the premises, and in most cases superannuation funds are in existence to provide for the members of the staffs after a number of years of service. I was very much struck with the comprehensive way in which these undertakings are generally organised and carried out, and although I am loth to say so, I must confess that in the matter of central-station practice generally we have many lessons to learn from the Continent. The result of this trip on the Continent convinced me that my late report as to the future system of supply for Sheffield was based on the right lines, and I have every confidence in proceeding with the work of changing over our present monophase system to polyphase. Further, I have every reason to be satisfied that I am conforming to the latest up-to-date practice in laying down a new polyphase power station and converting the old one, and I trust that what I have reported will lead you to share with me the confidence I have in these proposals. Finally, I have to express my cordial thanks to all the officials of both the public and private undertakings I have visited for the very courteous attention and consideration shown to me.

COMPANIES' MEETINGS AND REPORTS.

WEST INDIA AND PANAMA TELEGRAPH.

The ordinary general meeting took place on Wednesday at Winchester House.

Mr. William Andrews, the chairman, in moving the adoption of the report, referred to the line competing with them, which he said worked at artificially low rates The object of the aid solicited by them from the Colonial Office was really and in practical effect aid to the West Indies. The Treasury regarded with disfavour applications for aid. The directors were pleased to see of late that prospects were held out of a revival of West India trade and commerce and they would like to see extended to this Company a little of the liberality which had been exhibited in the direction of Messrs. Elder-Dempster's steamers.

Mr. Henry Holmes seconded the resolution, which was carried.

Digitized by Google

CAPE ELECTRIC TRAMWAYS.

The ordinary general meeting of this Company was held on Wednesday at Winchester House. Sir Charles Euan-Smith presided.

The **Chairman** referred to the fact that two interim dividends, making together 9 per cent., had been paid, as compared with 6½ per cent. in the preceding year. The sum of £20,000 had been carried to the credit of reserve, against £8,000 last year, and it was now proposed to make a further payment of 3 per cent. on the share capital, leaving £12,000 to be carried forward.

The report was adopted and the bonus approved, and the following resolution was unanimously agreed to: "That the capital of the Company be increased by the creation of 100,000 additional ordinary shares of £1 each, ranking for dividend and in all other respects *pari passu* with the existing ordinary shares of the Company, and that the directors be empowered to dispose of such shares to such persons and on such terms as the Board may think fit."

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ilford.—The Urban District Council invite tenders for the supply of lamp columns in quantities of about 50 at a time. Tenders by Nov. 26.

Kendal.—The Corporation invite tenders for the supply and erection of various plant. Tenders by Dec. 1. Details in our advertisement columns.

Bristol.—The Electrical Committee invite tenders for electric travelling crane and condensing plant. Tenders by Nov. 22. Details in our advertisement columns.

Brighton.—The Council invite tenders for the construction of the permanent way of the tramroads. Tenders by Dec. 13. Details in our advertisement columns.

Halifax.—The Tramways Committee invite tenders for tramcars, trucks, motors, and electrical equipment for same. Tenders by Nov. 27. Details in our advertisement columns.

Newcastle-upon-Tyne.—The New Tramways Committee invite tenders for arc lamp cables, telephone and pilot wires. Tenders by Nov. 21. Details in our advertisement columns.

Newcastle-upon-Tyne.—The New Tramways Committee of the Corporation invite tenders for arc lamps and accessories. Tenders by 21st inst. Details in our advertisement columns.

Cuevas (Spain).—Applications are invited by the Municipality for electric lighting of the town for 20 years. Tenders by Nov. 30. Specification, etc., may be seen at the office of this paper.

Bermondsey.—The Vestry invite tenders for arc lamp columns, arc and incandescent lamps, automatic switches, and fittings. Tenders by Dec. 3. Details in our advertisement columns.

Hendon.—The Urban District Council invite tenders for the supply and erection of various plant for the municipal electricity works. Tenders by Dec. 31. Details in our advertisement columns.

Belfast.—The Gas and Electric Committee invite tenders for switchboard extensions. Specifications, etc., may be obtained on application to Mr. Victor A. H. McCowen, city electrical engineer. Tenders by Nov. 23.

Nottingham.—Tenders are invited for the installation of an electric lighting plant at the new workhouse. Specifications may be obtained from Mr. G. Muncaster Howard, clerk, Poor-Law Offices, Nottingham.

West Bromwich.—The Corporation invite tenders for the supply of wiring materials, motors, and labour in wiring for lighting and power installations. Tenders by Nov. 17. Details in our advertisement columns.

Oldham.—The Electricity Committee invite tenders for the supply, delivery, and erection of an extension switchboard for supplying current for the tramways. Tenders by Nov. 27. Details in our advertisement columns.

Cardiff.—The Corporation invite tenders for the following: (Section 4) 75-kw. motor-generator and Tudor storage battery; (5) lead-covered cables; (6) 20-ton travelling crane. Tenders by Nov. 28. Details in our advertisement columns.

Oldham.—The Tramways Committee invite tenders for the erection of a tramway car depot at Wallshaw, within the borough. Specifications, etc., may be obtained from Mr. S. A. Pickering, A.M.I.C.E., borough surveyor, Town Hall, Oldham. Tenders by Dec. 5.

Wolverhampton.—The Tramways Committee invite tenders for erection of car depôt, paint and repair shops, etc., at Cleveland-road. Plans, etc., may be seen at the office of Mr. J. W. Bradley, C.E., M.I.M.E., borough engineer, Wolverhampton. Tenders by Nov. 19.

Brighton.—The Council invite tenders for the supply and delivery of the following: points, crossings, etc., soleplates, manhole covers with frames, gully grates with frames, tie-bars, fish-bolts, and other bolts for fastenings, etc. Tenders by Dec. 6. Details in our advertisement columns.

Greenwich.—The Guardians invite tenders for proposed electric lighting installation at the new workhouse, Grove Park, S.E., now in course of erection. Specification, etc., may be obtained and plans seen at the Greenwich offices of the architect, Mr. Thomas Dinwiddy, F.R.I.B.A. Tenders by Nov. 22.

Leeds.—The Corporation invite tenders for the various works required in erection and completion of buildings in extension of the present electric lighting works in Whitehall-road. Plans, etc., may be obtained from Mr. H. Dickinson manager, Electric Lighting Works 1, Whitehall-road, Leeds. Tenders by Nov. 27.

Oldham.—The Tramways Committee invite tenders for the supply and erection of the iron and steel work required in the completion of a car depot at Wallshaw, within the borough. Specification, etc., may be obtained from Mr. S. A. Pickering, A.M.I.C.E., borough surveyor, Town Hall, Oldham. Tenders by Dec. 5.

Stockport.—The Tramways Committee invite tenders for the supply and delivery of about 1,050 tons of grooved steel girder tramway rails, fishplates, tiebars, bolts and nuts, points, and crossings. Plans, etc., may be obtained (£3. 3s.) from Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Shoreditch.—The Vestry invite tenders for the supply of various plant for the new generating station at Whiston-street, including direct-connected direct-current generators of an output of about 800 kw. each set. Specifications, etc., may be obtained at the office of the Vestry's electrical engineer, Mr. C. Newton Russell, Electric Light Station, Coronet-street, Hoxton, N. Tenders by Nov. 20.

Stockport.—The Tramways Committee invite tenders for the overhead equipment and supply of rail bonds for six sections of their electric tramways, having a total length of about 2 miles 3 furlongs 5 chains double line, and 2 miles 2 furlongs single line. Specifications, etc., may be obtained from Mr. A. J. H. Carter, electrical engineer, or Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Stockport.—The Tramways Committee invite tenders for the laying of the permanent way of their electric tramways, including concrete foundation, but excluding bonding and paving, in six sections, having a total length of about 2 miles 3 furlongs 5 chains double line, and 2 miles 2 furlongs single line. Plans, etc., may be obtained on application to Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Alteerig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

RESULTS OF TENDERS.

Worthing.—The Electric Lighting Committee have accepted the tender of Messrs. Oliver and Co. for Contract No. 8 (arc lamps), at £850. 17s.

Avonbank (Bristol).—The Electrical Committee have accepted the tender of E. Nuttal, Manchester, for the erection of a power station at Avonbank.

Walsall.—The Electric Lighting Committee have accepted the tender of Mr. A. Lynex for erecting the timber required for a temporary switchboard for £6. 17s. 6d.

Cardiff.—The tender for 1,000 tons of steel rails for the relaying of the tramway track for electric traction in Cardiff has been secured by Messrs. Dick, Kerr, and Co., of Glasgow.

Bermondsey.—The following tenders have been accepted: Thames Ironworks Company, engines, electric generators, etc., £4,334; J. Spencer, Limited, pipes, pumps, etc., £2 672. 10s.

Sheffield.—The Corporation have accepted the tender of the Electric Construction Company, Wolverhampton, for two two-phase steam alternators (600 kw.), and for alterations to present single-phase plant, at schedule rates

Aberdeen.—The Tramway Committee have accepted the tender of the British Westinghouse Company, Limited, Westinghouse-buildings, Norfolk-street, Strand, W.C., for the manufacture and supply of 12 electrical tramcars, and equipments for six horse cars about to be converted.

Bedford.—The Electric Light and Traction Committee have accepted a contract with the Midland Railway Company to carry a conduit containing cable over, and erection of lamps upon, the Kempston-road bridge. The committee have also accepted the tender of Mr. W. Laughton to build two underground sub-stations, at £33. 10s. each.

BUSINESS NOTES.

LIGHTING AND GENERAL.

Bedford.—Several extensions of cable have been agreed to.

Lichfield.—The City Council propose to apply for a provisional electric lighting order.

Finchley.—The School Board are favourable to electric lighting, and in all probability will use it.

Aylesbury.—A special report of the Lighting Committee has been before the Council in committee.

Accrington.—The electricity works are practically completed. Current was turned on for the first time on Friday.

Digitized by Google

East Grinstead.—The Urban District Council have decided to apply to the Board of Trade for a provisional order for electric light.

Hereford.—The Town Council have decided to apply for sanction to borrow an additional amount for electric light extensions.

Trowbridge.—Two schemes, estimated to cost £17,000 and £28,000 respectively, are recommended to the District Council for electric lighting.

Worksop.—The Council have concluded a loan of £5,000 (part of £30,000 proposed to be raised for the purpose of electric lighting) at 3½ per cent.

East Ham.—The District Council have agreed to an extension of arc lamp lighting at a cost of £557. The annual charge per lamp is stated at £18.

Electrical Power Distribution Co.—Letters of allotment for the recent issue of shares by the Electrical Power Distribution Company have been posted.

Potteries.—The Potteries Electric Traction Company propose to apply to the Board of Trade for powers to improve and extend their system in North Staffordshire.

Keswick.—The resolution previously passed by the Urban District Council refusing to allow the Postmaster-General to fix telephone wires and poles in the streets has now been rescinded.

African Telegraphs.—With the completion of the telegraph from Brazzaville to Libreville, in the French Congo, the district of Stanley Pool is now brought into direct communication with Europe.

Gosport.—The Council have assented to the application of the Portsmouth Town Council for a municipal telephone exchange, subject to the Council being consulted as to the breaking-up of their roads.

Ilford.—The charge for electricity has been fixed at the rate of 8d. per unit for the first hour per diem on the maximum demand, and a rate of 2d. per unit per diem for all current consumed after.

Norton.—The Rural District Council have formally consented to the obtaining by the Sheffield Corporation of the power to construct an extension of the Woodseats tramway from Woodseats to Abbeydale, *vid* Abbey-lane.

Oban.—At a recent meeting of the ratepayers a resolution was passed approving of the resolution of the Town Council to apply for a provisional order to supply electrical energy for public and private purposes within the burgh of Oban.

Arbroath.—The Government intend to erect a telegraph wire between Arbroath and the coastguard station near Auchmithie, in order to facilitate communication between the coastguard station and the town in case of wrecks off the coast.

Walsall Telephones.—The Chamber of Commerce recently decided to communicate with the chambers of commerce in other towns of about the same size as Walsall in order to ascertain whether the telephonic system is as bad in those towns as it is in Walsall.

East Barnet.—The Urban District Council have decided to oppose the North Metropolitan Electrical Power Distribution Company's application for a provisional order to supply electrical power in the Council's district under the Electric Lighting Acts, 1889-1892.

Saltburn.—At the November meeting of the Urban Council the question of purchasing the electric lighting station plant, etc., from the Assets Company was discussed, and it was decided to ask the Assets Company if they were prepared to entertain an offer of £8,000.

Rathmines.—The Urban District Council have agreed, owing to the numerous applications for electric lighting, that additional generating plant should be obtained at an estimated cost of £7,500. Mr. Hammond has been instructed to prepare specifications and invite tenders.

Southgate.—The Urban District Council have received from Mr. Carpenter a report on the proposed joint scheme for electric lighting, and afterwards sealed the agreement between Edmonton, Tottenham, Southgate, Enfield, and Wood Green for the promotion of a joint Bill in Parliament.

Worcester.—It is proposed to purchase, at a cost of £3 750, a site in the Hylton-road whereupon to erect a supplemental electricity generating station, in view of the conversion of the city tramways for electrical traction and their extension as light railways in the surrounding districts.

Foots Cray.—Application is to be made to the Board of Trade for a provisional order for public and private lighting within the parish of Foots Cray, and within that portion of the parish of Chislehurst known as the lower borough, in the district of the Urban District Council of Chislehurst.

Romford.—In reply to a letter from the Board of Trade, with an application by Messrs. Ind, Coope, and Co., Limited, for exemption from the operation of the by-laws proposed to be made in respect of the electric light cable across South-street, the Board of Trade will be asked that no exceptions be made.

Taunton.—The Electric Light Committee of the Town Council in their last report state that they are in communication with the British Electric Traction Company as to the terms agreed upon by the Council for the supply of current for the trams, and hope to report further upon the matter at the December meeting.

Stoke Newington.—A special meeting of the new Council was held last night to consider report of special committee *re* site for electric light works, etc., as to obtaining parliamentary powers for the compulsory purchase of a site under Section 5 (2) of the London Government Act, 1899, and Section 65 of the Local Government Act, 1888.

Shoreham.—The Harbour Trustees have agreed to the plans for the Brighton Corporation's generating station, and have decided that in consideration of the diminution of the Trustees' water rights by the erection of the proposed new electricity works on Shoreham Harbour, a claim of £200 be made on the Brighton Corporation in respect of the same.

Recording Telegraphs.—In the Companies' Winding-up Court on Wednesday, Mr. Justice Wright had before him a petition for the compulsory winding-up of Recording Telegraphs, Limited, presented by Messrs. Segrue and Co., Limited. The matter was allowed to stand over for a week, so that copies of the affidavits might be prepared for all the parties concerned.

Brighton Telephones.—With regard to the municipal telephone scheme which Mr. Bennett is preparing, we learn that provision is being made in the specification for the tramways for the necessary conduits for laying the underground telephone wires, such conduits being stoneware pipes of the same description as those to be used in connection with the tramways.

Walsall.—The total number of consumers supplied on Oct. 31 last was 168. An application has been made by the Hospital Bazaar Committee for a gratuitous supply of electric current during the holding of the forthcoming bazaar, but as it would be creating a precedent which might cause difficulty in the future, the committee were unable to accede to the request.

Football.—On Saturday last Glover's Cables met and defeated Royce's Dynamos by three volts to two. The scores fairly represented the play, and Royce's are to be congratulated on playing such a good game against the premier Manchester electrical football club. We have been asked to state that Glover's still have some dates open for matches against similar organisations.

Whitehaven.—The borough engineer's report states that more satisfactory progress has been made in the work of extension at the electric lighting station. The Town Council have informed Messrs. Raybould that they had given the Water and Lighting Committee power to cancel their contract, but they had decided to postpone any action to see what progress was being made.

Manchester.—Mr. C. H. Wordingham, the chief engineer at the electric light works, has intimated to the Electricity Committee of the Corporation that he will not renew his engagement at the expiration of his agreement on March 31. He has been with the Corporation about seven years, during which time he has had charge of the rapid developments of the electricity undertaking.

Inverness.—Mr. Craven, engineer of the abandoned electric lighting scheme for the town, has accepted the Town Council's offer of commission at the rate of 2½ per cent. on £27,000, the amount stated in his account as the total cost of the scheme, under deduction of the sum of £300 already paid to account of commission. A special meeting of the Council has been called for Nov. 15.

Sale.—The Electric Lighting Committee of the District Council will at their next meeting decide as to whether the provisional order made by the Local Government Board should be put into operation. In the meantime, the chairman has been requested to interview the chairman of the Stretford District Council, and ask as to whether it was probable that Stretford would be supplied by Manchester.

Northfleet.—The District Council have come to a very practical resolution—viz: "That the railway company be invited to consider the advantage of having the telephone in the office of their goods station, so that on the first arrival of the goods an intimation may be given to those consignees on the telephone service of the arrival of their goods, and requesting that they may be removed in the course of the day."

King's Lynn.—The engineer's last report states that there are now 226 applications for the supply of current, representing 7,244 lamps of 8 c.p., an increase of 308 during the month. The new feeder mains have been delivered by Messrs. Callender, and are now in daily use. The first engine and dynamo and new boiler are expected to be delivered in contract time. The last set of new exhaust boxes has been fixed.

Canterbury.—Mr. R Hammond has been instructed to prepare specifications and obtain tenders (subject to the consent of the Local Government Board) for an extension of the lighting plant, consisting of extensions of boiler and engine house plant, steam-pipe work, accumulators, switchboard, instruments and buildings, and foundations for plant. The resident engineer is about to prepare a scheme for main extensions.

Normanton.—A conference was held on Wednesday to discuss the advisability of sanctioning the carrying out of the electric lighting and an electric tramway scheme by the United Kingdom Electrical Association. The following Councils were represented: Featherstone, Pontefract, Castleford, Whitwood, Warmfield, and Syndale. A sub committee, consisting of two from each Council, is to be appointed to further investigate the matter.

Limerick.—Consequent on the refusal of the Local Government Board to sanction at present the loan of £20 000 for the carrying out of an electric lighting scheme, the Board of Trade have decided to defer consideration of the question of revoking the order for 12 months from Nov 9, 1900. A deputation from the Corporation will wait on the Local Government Board in Dublin this week with a view to the loan in question being granted.

Sleaford.—At the last meeting of the Urban District Council several applications for gas lamps for street-lighting were held

Digitized by Google

over until the Local Government Board had forwarded their decision as to the application for a loan of £7,000 to provide an installation of electric light for Sleaford, under the control of the Council. Complaints were received from various sources of a nuisance caused by offensive odours emanating from the town gasworks.

London Electrical Cab.—This matter, which had been before Mr. Justice Wright in the Companies' Winding-up Court on previous occasions on a petition for a compulsory winding-up, was mentioned last week. The petitioners, having consented to his Lordship's suggestion that a provisional liquidator should be appointed, an order was made that the official receiver should be appointed provisional liquidator. The question of costs was left over.

Bournemouth.—The Guardians have received a letter from the Local Government Board enclosing a copy of an extract from a report made by their architect, Mr. Gordon Smith, with reference to the proposed installation of electric lighting at the workhouse and cottage homes. The matter has been referred to the Buildings Committee, and Mr. Peers (the engineer who has advised the Board with respect to the scheme) has been asked to attend the meeting of the committee.

Thornhill.—At the last meeting of the District Council a circular was read from Messrs. Bennett and Ward-Thomas, electrical engineers, drawing the attention of the Council to the fact that a syndicate intended to apply to Parliament for an Electric Power Bill to supply the district of Thornhill, along with others. They suggested that districts should combine in opposing private companies, and to promote an alternative scheme, and proposed to send one of their representatives to meet the Council. It was agreed to confer with such representative.

Ashton.—At Friday's meeting of the Town Council Mr. Vincent tendered his resignation, he having obtained an appointment under the Bermondsey Vestry. It was resolved that Mr. Vincent's resignation be accepted with sincere regret. Mr. Bruton, the second engineer, is to take charge of the work between the time of Mr. Vincent leaving and the appointment of his successor. It was also resolved that the whole of the existing disconnecting boxes laid under the footpaths be bricked in at once, and that all additional boxes be laid in the same manner.

Sheffield.—At Friday's meeting of the Town Council the Town Clerk read a communication from the Yorkshire Electric Power Syndicate, which, he said, proposed to apply for parliamentary powers to supply electricity in bulk to local authorities, and also to supply it to manufacturers who desired it. As the latter proposal would be a distinct interference with the privilege of the Corporation, he suggested that the communication be referred to committee. It was decided to refer the matter jointly to the Parliamentary and Electric Light Committees.

Middlesbrough.—Applications have just been granted for 615 lights from different consumers short distances from the cables, requiring the purchase of a quarter of a mile of cable. The North Ormskirk Urban District Council have been enquiring if the Middlesbrough Corporation could supply electric power in bulk. A Bill is to be promoted next session for powers to supply electricity to the whole of Cleveland, Middlesbrough, and Hartlepool. The Council will probably oppose this measure. The works being practically finished, supply will be started some time in December.

London County Council.—At the meeting of the Council on Tuesday tenders for the supply of arc lamps for the Victoria-embankment and Westminster Bridge were received, and referred at once to the Highways Committee for report. Upon the recommendation of the Finance Committee it was agreed to lend the Hampstead Guardians £2 005 for erection and equipment of laundry and boiler-house, and for the installation of electric light at their workhouse. The fee for telephonic communication with the fire brigade stations was reduced from £5 to £2. 2s. per annum.

Whitby.—Two plans have been prepared for a new opening bridge at Whitby on a much larger scale than the existing one. One plan provides for an ordinary swingbridge with an opening span of 60ft. for boats, and two side spans of 30ft. and 40ft. respectively, at a cost of about £15,000, and a temporary bridge for the same £3 500, making a total cost of £18,500. This plan would be worked by electricity, and in this case the Council could use some of their surplus power at the electric light works. The matter has now been referred to the Highways and Sanitary Committee.

Appointments Vacant.—The Brighton Corporation require a junior assistant in their testing department, to assist with meter and dynamo indicator testing.—The Gas and Electric Committee of Belfast are prepared to receive applications for junior assistant in the mains department and an improver.—The electricity department of West Ham require the services of a first-rate cable jointer. Full particulars of these vacancies appear in our advertisement columns.—The Whitehaven Electric Lighting Committee will advertise shortly for a mains foreman at a commencing salary of 35s. per week.

Paignton.—The District Council have had under consideration the lighting the town with electricity, but they have been unable to take any active steps owing to the initial cost, and the fact that they already have their hands full of big schemes. Mr. Paris Singer has come forward and has offered to undertake the whole cost of lighting the central part of the town with electricity, and to give the town the option of purchase within any reasonable time for exactly the same sum that the works cost him. The Lighting Committee have been instructed to meet Mr. Singer and go into the matter with him.

London Gazette.—Notices of intention to apply for provisional orders have appeared in the *Gazette* as follows: Whitley and Monkseaton electric lighting (A. G. Robson and others), Alfreton (Urban District Council), Hindley (Urban District Council), Roundhay and district (Roundhay and District Electric Lighting Company). Application is to be made to the Light Railway Commissioners by the London and South Western Railway for the construction of a light railway between Ratfyn and Shrewton, Wilts. The liquidators in the estate of the Chitty Dynamo and Motor Company, Limited, 4, Hythe-road, Willesden, have been discharged (Nov. 10).

"English Illustrated Magazine."—The November number of this bright magazine is unusually interesting. This month's instalment of the adventures of Mr. Archibald Batts brings sport up to date by means of electric appliances provided by the thinly-disguised firm of Gaskelyne and Brooks. Mr. Halliwell Sutcliffe has a vigorous tale to tell of the time when Mary queened the Scots, and Mr. Hamilton Drummond is adding to his reputation by showing how Diego Roseas cheated the *oubliette*. There are many other good things provided—in fact, the shorts are all the best of their kind, and the more instructive essays are well worth reading, and are beautifully illustrated.

Morley.—The chairman of the Electric Lighting Committee and the engineer have been empowered to advertise and appoint a successor to Mr. Ely as electrician-in-charge. Enquiries are being made as to charges made elsewhere for current supplied through penny-in-the-slot meters, and as to wiring of premises either by the Corporation or the free wiring companies. The engineer is preparing an estimate of the capital expenditure for the next five years, and application is to be made to the Local Government Board for sanction to the necessary loan. Steps are being taken to extend the cables to Bank-street, Rooms-lane, and Barfield-terrace, and new meters are required.

Kensington.—The Special Electric Lighting Committee recommended at the last meeting of the Guardians that the workhouse, infirmary, and offices in the Marloes-road be lighted with electricity, to be manufactured on the premises, and that Prof. Robinson be instructed to prepare the necessary plans and specifications for the works required at an estimated cost of £12,500. The Clerk read a lengthy report from Prof. Robinson, in which he showed that both for economy and convenience the Guardians should manufacture their own supply of electricity. Decision was deferred until this report had been printed and issued to the members. It appears, however, that the majority of the committee were in favour of having their own plant.

Walker and Wallsend Union Gas Co.—An extraordinary general meeting of the shareholders was held in the Company's offices, Mitchell-street, Walker, on the 9th inst., at which the following resolution was adopted: "That the Company create and issue the whole of the ordinary shares remaining unissued in the electricity capital of the Company, authorised by the Walker and Wallsend Union Gas Company's Electric Lighting Act, 1899, and raise £25,000, part of the additional capital authorised by the Walker and Wallsend Union Gas Company's Electrical Capital Act, 1900, by the creation and issue of new ordinary or preference shares of the nominal amount of £10 each, or of new ordinary preference stock as the directors may from time to time determine, and that the directors be hereby authorised from time to time to dispose of such shares or stock in such manner as the directors shall think advantageous to the Company.'

"The Practical Engineer Pocket-Book."—We have received from the Technical Publishing Company, of 31, Whitworth-street, Manchester, a copy of the edition of the "Practical Engineer Pocket-Book" for 1901. In this new edition great care appears to have been taken to bring it up to the usual high standard to which it attains. The book is now in its twelfth edition, and is kept thoroughly up to date. Amongst the additions to the volume we notice the recommendation of the Institution of Civil Engineers upon the best standard of efficiency for steam engines. The steam-engine has received much attention in the book this year, there being extra tables added for the finding of steam pressures, etc. We are sorry to see that electrical engineering has but a small place in the practical engineer's estimation, as even if the ordinary engineer does not have much to do with electricity there are times when a little information on another branch of engineering may prove very useful. At the end of the pocket-book is a diary, the pages of which are square ruled, which should be very convenient to the engineer wishing to make notes to scale.

Fatal Shocks.—A fatal accident occurred on Monday afternoon at the Corporation electricity works at Newport, Monmouth. Mr. T. W. Griffiths, an assistant engineer, while on duty at the switch-board, received a shock which resulted in his death. The inquest on the deceased was formally opened on Wednesday and adjourned until to-day (Friday). The result of the post-mortem is, up to the time of writing, not known. The accident, which is very regrettable, is the first of the kind which has happened at the Newport works. It is suggested that the deceased was engaged at the time of the accident in screwing up a nut on a portion of the apparatus, and was in a stooping attitude whilst using the spanner on the nut. The spanner is then thought to have thrown deceased's left knee against a live portion of the apparatus, there being a slight burning mark on the knee-cap.—Another case of fatal shock is reported from Cheltenham, where a young man named Richard Edwards, in the employ of the Corporation, was on Tuesday afternoon killed by an electric shock while at work on a cable junction.

Stock Exchange.—The Stock Exchange Committee have appointed Nov. 28 as a special settling day for the British Electric

Digitized by Google

Traction Company, Limited, further issue of 10,000 6 per cent. cumulative preference shares of £10 each, fully paid, Nos. 110,001 to 120 000; and 15,000 ordinary shares of £10 each, fully paid, Nos 75,001 to 90,000, and have ordered them to be quoted in the official list. The committee have also ordered the undermentioned securities to be quoted in the official list: City of Buenos Ayres Tramways Company, Limited, further issue of 20 000 shares of £5 each, fully paid, Nos. 135,001 to 155,000; Willans and Robinson, Limited, further issue of 10 000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 60,001 to 70 000. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to the Blackheath and Greenwich District Electric Light Company, Limited, provisional certificates for £100,000 4½ per cent. first debenture stock, and to the Notting Hill Electric Lighting Company, Limited, further issue of 2,200 ordinary shares of £10 each, fully paid, Nos. 10,001 to 12 200.

Partnership.—Mr. Alfred H. Gibbings writes to inform us that he has taken into partnership in his consulting practice Mr. C. A. Baker, M.I.E.E. The firm will in future be known as Messrs. Gibbings and Baker. As much of Mr. Baker's experience has been gained on the Continent, a brief *résumé* of it will be of interest as showing the strength he will add to the new firm. After a course at the Hanover-square School of Electrical Engineering, and some experience with a contracting firm in this country, Mr. Baker was appointed assistant engineer to the electric lighting station in Milan, at that time the largest in Europe. This station has always maintained a foremost place, being owned and worked by the Italian Edison Company, who generated electricity on the low and high tension systems for electric traction, power, and lighting purposes. Mr. Baker was responsible for the erection of a complete central station for electric lighting at Pallanza, on Lake Maggiore, and the subsequent working of this station for a considerable period. On returning to England, Messrs. Callender's Cable Company, Limited, appointed Mr. Baker their resident engineer, with sole responsibility for carrying out a large contract in the city of London, during which time upwards of 200 men were working under his supervision, the difficulties of executing this work in crowded thoroughfares with a system of distribution requiring the most careful and prompt attention. On the completion of this contract Mr. Baker was employed by the same firm to carry out contracts for them in the Strand district of London, in Huddersfield, Sheffield, and Hull. After working for about three years in the South Wales district with Messrs. J. C. Howell and Co., where some extensive collieries and manufactories were equipped with electrical pumping, hauling, and lighting plants, Mr. Baker accepted a position at St. Petersburg. The Telegraph Manufacturing Company, Limited, of Helsby, arranged with him to go out to prepare plans and specifications for them in connection with a central electric generating station of 10,000 h.p. that it was proposed to equip there on the high-tension alternating system by a Belgian engineering firm. A contract for the manufacture, laying, and operation of the whole of the distributing system was arranged with the English firm, and Mr. Baker was appointed by them to act as their engineer and representative for the North of Russia, advising generally on all electrical matters in connection with the equipment of the new generating station. As many as 700 men were employed under Mr. Baker's direct supervision in the execution of the work entailed under this contract, which was satisfactorily completed and handed over in working order to the Russian authorities. Mr. Baker's appointment as representative of the Telegraph Manufacturing Company, Limited, necessitated his travelling considerably through Russia and Finland, thus extending his knowledge of men and things. We wish this new firm a successful career.

Brighton.—Application is so be made for a loan of £6 440—cost of lighting the tramway routes with 117 arc lamps, the maintenance of which is estimated at £20. 13s. 2d. each per annum. On Friday the Council adopted a report from the resident engineer as to the advisability of making a special tariff for the supply of electricity to churches. The engineer was of opinion that if churches held meetings and used light on weeknights, they could not in fairness expect any better terms than any other class of consumer. It was different, however, if they used more light on Sundays than weeknights (which was most probable), as they were then in a position to meet their requirements without in any way clashing their Sunday maximum demand with the ordinary weekday maximum load on the station. This also applied to other classes of consumers who were willing to use their demand at other hours throughout the week than the usual lighting hours. He suggested that all churches which agreed to pay an increased meter rental at £1 per annum might have their demand indicators short-circuited on Sundays, and thus have their accounts based on the weekday maximum demand, which in all probability would be so much less than their Sunday maximum as to make a very material difference in their annual accounts. This principle, if they would accept it, ought also to be extended to all other classes of consumer who on weekdays were willing or likely to only take a supply at other than the ordinary hours of lighting. Such an arrangement would meet perfectly the requirements of printing offices of morning dailies and such like, and those who agree to this method of obtaining their supply would, for an extra rental of £1 per annum, be provided with a time switch which would automatically prevent the demand being registered except during the usual lighting hours. The advantage of the above suggestion was that, while strictly adhering to correct principle of maximum-demand system of charging, it fully met the requirements of churches, midnight and daily users of electrical energy. In conclusion, therefore, he would strongly advise no departure from the present system of charging, except on lines similar to those he had indicated above. The committee approved the recommendation contained in the report, and that all consumers agreeing to pay an extra charge of £1 per annum for an automatic cut-out might have their demand indicator cut out all day on Sundays and on weekdays, except during the ordinary hours of lighting—viz., from dusk to 10 p.m. A letter was read from Mr. Christie, forwarding a letter from the Westminster Supply Company requesting the support of the committee to the application of the company for an alteration to the proviso to Clause 6, Section B, of the Board of Trade regulations of March 4, 1896. It was resolved that the town clerk should write to the Board of Trade in support of the application, so as to provide for an appeal to the Board in cases in which an alteration of the standard pressure in a whole district was prevented by the refusal of consent by a small proportion of the consumers in such district.

TRACTION.

Bowness.—The Urban District Council are in favour of a tramway scheme.

Personal. — Mr. Norman Thompson has been appointed secretary of the Tramways and Light Railways Association.

Paisley.—A strong endeavour is being made locally to form a company with a view to making application to Parliament for a tramways provisional order.

Port Glasgow.—The Town Council have received a formal undertaking from the tramways company binding themselves to apply for a provisional order for power to extend the tramways to Blackstone-buildings.

Dublin United Tramways Co.—The mileage worked by the Company is now 44 miles electrically and one mile by horses, as against 35 miles electrically and nine miles by horses for corresponding period last year.

Willington.—A local syndicate proposes to endeavour to obtain a Bill sanctioning the construction of certain electrical tramways on the north of the Tyne, including the district under the control of the Willington Urban Council.

Bolton.—The new electric tramways will, it is expected, shew a yearly profit of £20 000, and the Corporation have decided to promote a Bill in the next parliamentary session extending the roads and widening the principal thoroughfares of the town.

Colchester.—Messrs. Massey and Allpress have been engaged to carry out the preliminary engineering and other works connected with the Council's application for a provisional order authorising them to construct and work tramways in the borough.

Bath.—The company promoting the electric tramway scheme in Bath have agreed so conform to the wishes of the Rural District Council provided they pass over their roads. Certain conditions as to fares and routes suggested by them have been accepted by the Council.

Sheffield.—The Tramways Committee have instructed the tramways manager and the city surveyor to report upon the facilities of the Fitzalan Market as a site for a central station, and it has also been decided to obtain parliamentary powers to use the site of the market for this purpose.

Newport.—The Corporation discussed at some length on Friday the question of leasing the new electric tramlines or running the traffic directly under the control of the Corporation. The Traffic Committee's recommendation that at the expiration of Mr. S. Andrews's lease in July next, the tramway system be worked direct by the Corporation, was adopted.

Scarborough.—The New General Traction Company, Limited, have promoted a company, styled the Scarborough Electric Tramway Company, with a capital of about £150,000, which, it is understood, is practically already assured. The scheme which the company proposes for Scarborough is a comprehensive one, and is estimated to involve an outlay of £120,000.

Cleator Moor.—A proposal of a syndicate who intend to ask for power for the construction and equipment of a tramway from Cleator Moor to Maryport, and who desire to come to terms with the various authorities if possible, suggesting that the town clerks of Whitehaven, Maryport, and Workington should discuss their proposals, is before the Works Committee of the Urban District Council.

Dundee.—A new proposal has been brought forward by the burgh engineer with a view to avoid the steep gradient in Constitution-road. This has been favourably considered by the Tramway Committee, and is to be brought before the Council with the view of it being substituted for the route by Barrack-road. The proposed new route is both shorter and cheaper than the one formerly adopted.

Beetle.—The consideration of a proposal from the general manager of the Liverpool Corporation tramways to construct a tramway from Litherland to Rimrose Bridge through Seaforth Village, has again been deferred. A memorial protesting against the construction of this tramway along Seaforth-road has been referred to the Tramway Committee, and it has been pointed out that if a tramway was laid they must leave sufficient space, which would probably necessitate the pulling down and setting back of the houses, so that if the road was widened by that means it would dispose of a good many of the objections.

Digitized by Google

Erdington.—The Council have passed the following resolution: "That in the opinion of this Council the time had arrived when it would be to the advantage, convenience, and benefit of the inhabitants at large to have a system of tramways properly equipped and of an up-to-date character for the district; and that accordingly a committee be appointed to consider and report upon what in their opinion was the best system of tramways to be constructed, and to the roads along which they should be laid."

Gosport.—A small committee has been appointed to settle in a final interview with the companies' representatives in London the various tramway matters under discussion. The two agreements submitted by the Electrical Power Distribution Company and the British Electric Traction Company have been revised by the Council, and their alterations have been considered by the companies. The transfer of the existing system to the Corporation will take place on the last day of the year, and on the first day of the new century it is hoped to make a start with the relaying of the lines for the introduction of electric traction.

Northampton.—Application is to be made to the Board of Trade on or before Dec. 22 next for a provisional order under the Tramways Act, 1870 (to be confirmed by Parliament in the ensuing session), to authorise the Corporation to construct tramways in extension of the existing tramways in Kettering-road (as far as the Church of St. Matthew in Phippsville), and in Wellingborough-road, as far as the gates of Abington Park; to empower the Corporation to work any tramways for the time being belonging to them; to double the lines of such tramways where expedient; and to employ electrical or other mechanical motive power; and to make further and better provision in regard to the tramway undertaking for the time being belonging to the Corporation.

Bournemouth.—Mr. A. P. Trotter has held an enquiry into the application of the Corporation for sanction to borrow £174,750 for the construction and electrical equipment of a tramway authorised by the Corporation Tramways Order. 1900 The Town Clerk pointed out that the Poole and District Electric Traction Company had a light railway order to construct a tramway from Bournemouth to Poole, which was now being laid, and the Christchurch and Bournemouth Company had powers in their order of last session to construct a tramway between the two towns. They had running powers over the Bournemouth East line from east to west. The Town Council will now proceed with the application for the Bill for the tramways extensions, street widening, and other objects resolved upon.

Cleckheaton.—The Council have signed an agreement with the British Electric Traction Company, based on the arrangement made at the recent enquiry in Leeds, whereby the company undertake to pay half the cost of three widenings in Westgate in connection with their electric tramway scheme—viz., at the Square, at Victoria Mills, and at Moorbottom, near St. Luke's Church and Messrs. Umpleby's boiler works. The Council do not pledge themselves by the agreement to carry out any of the works, but whatever they did the Traction Company pledged themselves to pay half the cost at any time during the next three years. The expenses would include the cost of the acquisition of necessary properties, and the Council are entitled to call for payment of the half cost as soon as the works or any of them were completed.

Burton.—The tramway scheme adopted by the Council consists of six lines, and contains the following proviso: "That the carriages and trucks on the said tramways be moved by animal, mechanical, or electrical power, as the Town Council may from time to time determine." The promoters of the proposed Woodville and Burton tramways are to be informed of the tramways which the Council are seeking powers to construct, work, and maintain, and that the Council will consider any proposition as to running powers over that portion of the tramways between the borough boundary on the Stanton-road and Stapenhill-green which the promoters may desire to make, and that the clauses necessary for or relating to the carrying out the foregoing objects and incidental thereto be forthwith prepared and inserted in the draft Bill to be introduced by the Council into Parliament next session for the consideration of the Town Council.

Warrington.—At the last meeting of the Rural District Council a letter was read from the South Lancashire Tramways Company to the effect that the company were applying this year to Parliament for an extension of their tramway system from Newton, through the Warrington rural district, to the boundary of the borough of Warrington. The company obtained powers last session to construct certain tramways through St. Helens, Earlestown, Newton, Atherton, Leigh, and Bolton, with branches connecting these places with Haydock, Ashton, Abram, Hindley, Westhoughton, Little Hulton, Walkden, Swinton, Atherton, with Tyldesley and Worsley. It was proposed to make the extension to Warrington, in pursuance of the request of one or two local authorities last year. If the Council approved of the extension the company desired them to pass a resolution consenting to it. The matter was adjourned pending enquiries by the surveyor.

Baker-street and Waterloo Railway.—We refer elsewhere to the issue at par of 66 000 4 per cent. preference shares and 172,500 ordinary shares of £10 each which is just being made in this Company. Interest during construction will be paid half yearly at the rate of 3 per cent. per annum. The directors are Mr. Theodore Julius Hare (chairman), the Marquis of Dufferin and Ava, K.P., G.C.B., G.C.M.G., etc., Mr. Quintin Hogg, Major-General C. S. Hutchinson, C.B., late R.E., and the Right Hon. Sir Algernon West, K.C.B. The Baker-street and Waterloo Railway as authorised is five miles two furlongs in length, or thereabout, and will be formed by the construction of two separate parallel tunnels throughout its entire length on the Greathead system. Starting at the Elephant and Castle, on the south, it passes Waterloo Station, thence under the river, up Northumberland-avenue, Charing Cross, the Haymarket, Regent-street, Portland-place, Regent's Park, Baker-street, Marylebone Station (the terminus of the Great Central Railway), and Edgware-road, to Paddington Station. The site for the necessary depôt and generating station is about a quarter of a mile to the south of Waterloo Station. The stations will be placed at or near the following points—viz., Elephant and Castle, Waterloo, Thames Embankment, Charing Cross, Piccadilly-circus, Oxford-circus, Baker-street, Marylebone, Edgware-road, and Paddington. The line will thus form a connecting link between the District and Metropolitan, the Central London, the City and South London, the Waterloo and City, the South-Western Railway, South-Eastern Railway, Great Western Railway, London, Chatham, and Dover Railway, and the Great Central Railway. The works between Waterloo and Baker-street, which are being constructed by Messrs. Perry and Co., the well-known firm of contractors, are in full operation, and this section will be completed and opened for traffic independently of the rest of the line. From the river stage northward the western or down tunnel (towards Baker-street) has been driven beyond Piccadilly and up Regent street as far as the western end of Messrs. Swan and Edgar's premises. The up tunnel has been completed between the river stage and the statue of King Charles at Charing Cross, and between Swan and Edgar's and a point in the Haymarket opposite Her Majesty's Theatre. The tunnels at Baker-street have been driven under the St. John's Wood Railway, and underneath the Regent's Park; the down tunnel to the north side of the Park-square-gardens, and the up tunnel to the western side of the Outer Circle road. Southward of the river stage the down tunnel has been constructed nearly across the river, and the difficult operation of driving through the water-bearing gravel in the bed of the Thames has been successfully accomplished. The permanent shafts for the reception of the lifts have been sunk at Baker-street and Piccadilly, and one of the shafts is in progress at Waterloo. The up-station tunnel at Baker street has been completed. Both station tunnels at Piccadilly-circus are finished, and at Charing Cross one tunnel is completed and the other is in progress. At the Thames Embankment station the up tunnel is finished. An ample supply of shields and plant of all descriptions having now been provided, the works will proceed more rapidly than heretofore, and should be completed in two years from this date. It is needless to say that the motive power will be electricity, and it is anticipated that the entire distance will be covered in 25 minutes. The engineers are Sir Benjamin Baker, K.C.B., Mr. W. R. Galbraith, C.E., and Mr. R. F. Church, C.E.

LEGAL INTELLIGENCE.

LONDON COUNTY COUNCIL v. THE NATIONAL TELEPHONE COMPANY.

In the Queen's Bench Division on Monday last Mr. Justice Wills and a special jury commenced the hearing of the action by the London County Council against the National Telephone Company. The action raised an important question as to the right of the National Telephone Company to lay wires under the streets. The action was brought to restrain the defendants from breaking-up streets in the county of London to lay their telephone wires underground without the consent of the London County Council. The case was put in two ways: first, that under the Telegraphs Act the defendants had no right to do what they had done; and, secondly, they were creating obstruction by breaking-up the streets. The defendants said they were not acting under the Telegraphs Act at all, and that they had created no obstruction. The plaintiffs, in reply, joined issue.

Mr. Dickens, Q.C., and Mr. Daldy appeared for the London County Council, and Sir Edward Clarke, Q.C., Mr. Joseph Walton, Q.C., and Mr. Roskill represented the Telephone Company.

Sir Edward Clarke asked for permission before the case was opened to called his Lordship's attention to some correspondence which had taken place between the solicitors of the National Telephone Company and the solicitors of the London County Council. This was one of two sets of proceedings which were brought against the National Telephone Company. One was brought by the Attorney General at the relation of the Postmaster General, and the other by the London County Council, and they substantially involved the same questions, as to whether an injunction should be granted, whether there had been an interference with public right, and so on. Both matters involved serious questions of law, as well as very complicated questions of fact. The information of the Crown came on first, and in that proceeding, which was before one of the Queen's Bench Courts in July, the National Telephone Company submitted to terms under which they were restrained, as between the Government and themselves, from doing any work for extending the existing system of the Telephone Company under the streets of London, and the whole object that could be achieved by going into the litigation which was then before his Lordship was, he thought, completely fulfilled by the terms which were arrived at in the former action. Under those circumstances his clients had written an open letter, to be used in the Court, to the plaintiffs' solicitors, and he asked that he might be allowed to read it. The letter was as follows: "As the trial of this action will shortly be reached, it is worth while considering the position as between the parties. As you are

Digitized by Google

no doubt aware, an information by the Attorney-General, at the instance of the Postmaster-General, was laid against the company with a similar object to that sought by the County Council in the present action, and the Crown action has been disposed of by an order which declares the law and restrains the company from breaking the surface of any street within the county of London for the purpose of extending its underground pipes without obtaining the authority of the Postmaster-General and the consent of the London County Council, as required by the Telegraphs Act of 1892." He thought that put the Telephone Company in a position which carried out all that the County Council in this litigation could require. The letter went on: "It seems to me to be a useless waste of money to fight out the present action, seeing that the order made in the Crown action secures to the County Council what it requires, and I have, therefore, to suggest that instead of going to trial at present the County Council action should be allowed to stand over *sine die*." The reply of the representatives of the London County Council was that they did not think it desirable that the action should stand over. The solicitor of the County Council wrote: "I have some difficulty in understanding why the Telephone Company, after submitting to judgment in the Post Office information, has nevertheless persisted in defending the present action. The order in the Crown action does not appear to me to secure anything at all to the County Council, for it would be open to the Telephone Company to arrange its differences with the Postmaster General to-morrow, and, therefore, so far as that judgment is concerned, to continue breaking-up the streets. If, however, the Telephone Company will consent to a similar judgment in the present action I am prepared to advise the Council to accept it, and so put an end to the litigation." Sir Edward Clarke proceeded to say that the Telephone Company could not consent to judgment or to anything, or to give an undertaking in this action. His Lordship would understand there were considerations with regard to the position of the parties which would prevent him under any circumstances submitting to a judgment. The case must involve a very long investigation of facts, and on the finding of the jury his Lordship would be asked to deal with questions of law and to exercise his discretion in granting an injunction. The litigation could not in any case stop there. He was very much impressed with the idea that it would be a misfortune if they were to spend several days of public time there to come only to the position of having the material for going into another court when all that could be done in this litigation was already secured by the terms of the judgment in the other action.

Mr. Dickens said there was a difficulty in the way of accepting his friend's suggestion. There were two proceedings, advisedly commenced by the Attorney General on the basis of the interest of the Postmaster General, merely representing the Post Office service in this country, and by the London County Council as representing the public. The two interests were not identical. The defendants submitted to an injunction in the action of the Postmaster General, and they were bound to obtain the consent of the County Council before breaking open the streets. He did not wish to enter into a long litigation in the present case, but he had not seen the members of the Highways Committee, and he would not like to consent to the suggestion of Sir Edward Clarke without consulting them.

Mr. Justice Wills said at the present moment he did not quite appreciate the difficulty of the Telephone Company in giving an undertaking similar to the one given to the Postmaster-General. He supposed it was very likely that the Postmaster-General would allow them, after getting that judgment, to break up the streets without obtaining the consent of the London County Council. On the other hand, the County Council had not got the security as between themselves and the defendants.

Sir Edward Clarke said if his Lordship would look at the pleadings he would find there were serious questions, which made it impossible for the Telephone Company to come under the terms of an injunction or an order. There were important legal questions which they wanted to raise. Precisely the same result might be obtained if the action stood over generally, with leave to apply to restore it; and if the Telephone Company was to do anything in contravention of the injunction, the case might come into the paper the next day. If it were a mere technicality, he would give way.

His Lordship did not think the course proposed by Sir Edward Clarke was an unreasonable one. Probably he would give the plaintiffs an undertaking not to attempt to do anything in contravention of the order obtained by the Postmaster-General without giving the County Council due notice of it.

Sir Edward Clarke said he was quite prepared to agree, and to undertake, on the part of his clients, that no action should be taken in contravention of the Postmaster-General's order without giving notice to the London County Council, so that they could have an opportunity of applying at once.

Mr. Dickens said he was glad that his Lordship had made the observation that the course suggested by Sir Edward Clarke was reasonable. Having regard to the importance of the matter, he would ask that the action might stand over for a fortnight in order that he might put the proposition and his Lordship's suggestion before his clients. If the matter could be arranged, they would only have to come formally before the Court. If the case must go on, the plaintiffs would not be in a worse position than at present.

Mr. Justice Wills thought the best form of order would be that the case should stand over generally to keep its place in the list, with leave to either party to restore it. If any terms were come to, the case could be mentioned without its being put in the paper.

The action was then ordered to stand over generally.

NEW COMMITTEES.

The following Standing Committees have been appointed:

ABERDEEN.—*Streets*: Bailie Brebner (convener); Messrs. Smith, Anderson, and the Provost.

ALLOA.—*Lighting*: Bailies Home-Hay, Duff, and Calder; Messrs. Crawford, Duncanson, and Wilson; Mr. Duncanson, convener.

BACUP.—Five members of the Lighting Committee and five members of the General Works Committee are to be elected by their respective committees to serve on the Electricity Committee for the ensuing year.

BARROW.—*Highways and Lighting*: Alderman Bradshaw; Councillors Ashburner, Barrow, Charles, Dawson, Hardy, Heath, W. Heweteon, Jos. Huarteon, Miller, Neal, Peacock, Stoker, Thompson, Townsend, and Young. *Electricity*: Aldermen Bradshaw, Little, and Townson; Councillors Ashburner, Chapman, Cox, Fisher, Gradwell, Hardy, W. Heweteon, Miller, Postlethwaite, Smith, Peacock, Tootill, and Townsend.

BIRKENHEAD.—*Tramways*: Aldermen Cook, Deakin, B. Jones, Rawcliffe, and Singleton; Councillors Bevis, Edwards, Gamlin, Grice, Hazlehurst, Lilwall, Oates, H. L Pearson, Snape, and Wall. *Electricity*: Aldermen Bloor and Rawcliffe; Councillors Bennett, Dalzell, Dodds, Hazlehurst, Lilwall, McGaul, Moon, H. L. Pearson, T. T. Rees, Tooth, Wall, and C. Williams.

BLACKBURN.—*Electricity and Tramways*: The Mayor; Aldermen Thompson, Baynes, Oddie, Dugdale Heyworth, Law, Billington, and Hoyle; Councillors Lewis, Gregson, Meadowcroft, Crossley, W. H. Law, Hamer, Worswick, and Critchley.

BOLTON.—*Electricity*: The Mayor; Councillors W. Cooper, Young, Preston, J. Edge, J. W. Taylor, Russell Panton, Berry, Rothwell, Rideout, Golding, J. D. Taylor, and Fielding. *Tramways*: The Mayor; Aldermen Nicholson, Miles, and T. Scowcroft; Councillors Battle, Preston, Panton, Howarth, J. Edge, Flitcroft, Smith, Bailey, Wild (Deane), P. Higson, and Harwood.

BRADFORD.—*Electricity*: Aldermen W. E Aykroyd, J. Hustler, and R. Pratt; Messrs J. Akam, T. L Atkinson, T. Clark, F. L Crofts, C. E Dawson, J. Freeman, T. H. Shaw, and T. A. Williamson. *Tramways*: Aldermen Cowgill Holdeworth, and Milner; Messrs. Akam, Atkinson, Crofts, Crossland, Firth, Hartley, Hill, Horsfall, Land, J Moorhouse, North, Pickles, E. Priestley, W. E. B. Priestley, Sowell, P. Smith, Stringer, Watson, Whiteley, Wickham, T. Wilkinson, and Williamson.

BRIGHTON.—*Telephone*: Councillors Allen, Buckwell, Burberry, Carden, Galliers, Halliwell, Holder, Hollis, Jarvis, Kidd, Neale, and Wilson. *Tramways*: Aldermen Reeves and Sendall; Councillors Blaker, Buckwell, Carden, Galliers, Grinstead, Halliwell, Holloway, Swift, Wallis, and Wilson. *Light*: Aldermen Botting and Lowther; Councillors Blaker, Briant, Broadbridge, Buckwell, Butt-Thompson, Carden, Galliers, Halliwell, Holloway, and Swift.

BRISTOL.—*Electrical*: The Lord Mayor; Aldermen Pethick and Pearson; Messrs. Tryon, Hughes, Lloyd, Elkins, Billing, Harris, Chandler, Lowe, and Dr. Cook.

CANTERBURY.—*Lighting*: The Mayor; Aldermen Cross, Collard, and Mason; Councillors Gentry, Godden, Horsley, Hunt, Stone, Pope, and Russell.

DEWSBURY.—*Gas, Electricity, and Water*: The Mayor; Alderman Haley; Councillors Machell, McCann, Newsome, Oldroyd, Pearson, Rhodes, and Yates.

DUNDEE.—*Tramways*: Mr. Brownlee, convener.

EASTBOURNE.—*Electric Light*: The Mayor; Aldermen Skinner, Strange, Pocock, Wenham, and Eden; Councillors Hillman, Martin, Maude, Rowe, Simmons, and Wright.

ECCLES.—*Public Lighting and Electrical Supply*: Aldermen Kendal and Mellor; Councillors Broughton, Hindley, Mort, Nuttall, Oldfield, and Pearson.

FALKIRK.—*Lighting*: Bailie Bogle (convener); Messrs. Weir, Sherburn, Hendry, Mitchell, H. Wilkie, H. Russell, J. G. Russell, and Stevenson.

GLASGOW.—*Electricity*: Bailie Maclay, convener; Bailie M'Cutcheon, sub-convener. *Telephone*: James Alexander, convener; Bailie Stevenson, sub-convener. *Tramways*: Walter Paton, convener; Hugh Alexander, sub-convener. On telephone wire attachments to Corporation property—James Alexander, convener.

GLOUCESTER.—*Electricity Supply*: The Mayor (*ex officio*); Aldermen Estcourt, Matthews, Braine, Mousell, and Woodward; Councillors Karn, Clutterbuck, J. Clarke, Bland, Goddard, Hatton, Gurney, Poole, and Brown. *Street*: The Mayor (*ex officio*); Aldermen Estcourt, Matthews, Braine, Mousell, Ward, and King; Councillors Clutterbuck, Peters, J. Clarke, Goddard, Gurney, Poole, Brown, Estcourt, and Gream.

HOVE.—*Lighting*: Aldermen Clark and Washington; Councillors A. B. S. Fraser, Hollamby, Jupp, Nye, and Singer.

IPSWICH.—*Electric Lighting*: The Mayor; Alderman S. R. Anness; Councillors F. Bennett, E. Catchpole, R. D Fraser, J. Pratt, W. T. Pretty, E. P. Ridley, F. Turner, and Owen Turner.

KEIGHLEY.—*Gasworks and Electricity*: The Mayor; Aldermen Paget and Brigg; Messrs. Pollard, Newton, Snowden, Summerscales, and Walsh.

LEEDS.—*Lighting*: Alderman Lawson's name deleted; Mr. James in place of Mr. F. J. Pickersgill. *Tramways*: Alderman Gordon in place of Alderman Lawson.

Digitized by Google

LEIGH —*Highways and Works*: Aldermen Dennis, Howard, Ingram, and Tolhurst; Councillors Allen, Berry, Browne, Roberts, and Walker. *Light Railways*: Aldermen Brightwell, Burrows, and Dennis; Councillors Allen, Berry, Doody, Hudson, Jones, Martin, Millican, Roberts, and Wilkinson.

MANCHESTER —*Electricity*: The Lord Mayor; Aldermen Bax, Griffin, and Richards; Messrs. Arrandale, Batty, Beastow, Bishop, Bowes, Boyle, Hesketh, Jennison, Johnston, Maben, Phythian, J. Simpson, Smith, Vaudrey, and Wainwright. *Tramways*: The Lord Mayor; Aldermen Bax, Mainwaring, and Tunstall; Messrs. Batty, Bishop, Bowes, Boyle, Brocklehurst, Dearden, Dixon, Fildes, Edwyn Holt, Hodge, Hornby, Johnston, M'Cabe, Ogden, Scott, Sutton, Thompson, Trevor, Wainwright, Whyman, and Wilson.

MORLEY.—*Electric Lighting*: The Mayor; Aldermen Foster Horsfall, Binks, and Ingham; Councillors Watson, Glover, Oakes, Smith, Scholes, Hirst, Tetley, Craven, Rhodes, and Jowett. *Light Railways*: The Mayor; Alderman Glover; Councillors Buttery, Rhodes, Marsden, Scatcherd, Jowett, Tetley, and Smith.

NEWPORT.—*Lighting and Traffic and Electricity*: The Mayor; Aldermen Moses, Parnall, Jones, and Pugsley; Councillors W. J. Lloyd, Dunn, Liscombe, F. Phillips, G. W. White, Gower, M. A. Baker, G. H. Llewellyn, Abrahamson, and Blackburn.

NORTHAMPTON. — *Tramways and Electric Light*: Councillor Wooding (chairman); Aldermen Judge and Wetherell; Councillors Brown, Jackson, Lewis, Martin, J. Perkins, and Tonsley.

RAWTENSTALL. — *Electric Light and Tramways*: Aldermen Compston, Woodcock, Sharples, and Worswick; Councillors Coupe and Schofield.

ROTHERHAM — *Electric Lighting and Tramways*: Aldermen Woodhouse and Hickmott; Councillors Cox, Gichard, Winter, Crank, Hirst, Copley, Jenkinson, and Fieldsend.

SHEFFIELD.—*Electric Light*: Aldermen W. E. Clegg, Styring, and Sir Charles Skelton; Councillors Bennett, Colver, Nowill, Senior, Castle, Harrison, John Maxfield, G. Clark, and Tandy. *Tramways*: Aldermen W. E. Clegg and Styring; Councillors Chambers, Furness, G. Jackson Smith, Bennett, Fenton, A. M. Wilson, Wing, Knowles, Carr, Hobson, John Smith, Tandy, and J. R. Wheatley.

SOUTHAMPTON.— *Tramways*: Messrs. Dunsford, Bencraft, Pearce, Sanders, Tilling, Walton, Willey, Bone, Andrews, Hollis, Burbage, and Garcia. *Electricity*: Messrs. Blakeway, Cawte, Dunsford, M. Emanuel, C. Emanuel, Tilling, Willey, Bone, Le Feuvre, Button, Garcia, and Rowland.

TORQUAY.—*Electric Light*: Aldermen Kerswill and Bovey; Councillors Beavis, Harrison, Taylor, Pickard, R. Smerdon, Greenslade, Bowden, and Pearson.

WALSALL.—*Electric Lighting*: Aldermen Brownhill, Lindop, Marshall, and Newman; Councillors Brownhill, Burt, Cope, Millerchip, Noake, Shore, W. Smith, and Walker. *Tramways*: Aldermen Baker, Clare, and Newman; Councillors Brownhill, Cope, Cotterell, Hughes, Millerchip, Noake, Pearman-Smith, Powell, and Turner.

WORTHING.—*Electric Lighting*: The Mayor (Councillor Ovenden); Aldermen Linfield and Piper; Councillors Butcher, Gravett, Raffety, Tate, and Walter.

PROVISIONAL PATENTS, 1900.

NOVEMBER 5.

19782. Improvements in metal or composition sheathed insulated electricity conductors. David Roberts, 3, Whiston-street, Derby.

19809. An improvement in or in connection with trolley arm standards for electric railways or tramways. Stainer Hutchins and Charles Edmund Fry, Hawthorn Bank, Stamford-road, Altrincham.

19822. An improved conduit for electric cables and the like. Oliver Charles Summers, 82, Malmesbury-road, Bow, London.

19824. Improvements in and relating to printing by telegraphy. John Burry, 1, Broad-street-buildings, Liverpool-street, London. (Complete specification.)

19829. An improvement in electrical locking apparatus for railway signals. George Henry Jelfs, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

19836. Improvements relating to electric call apparatus. Max Joseph Buxbaum, 45, Southampton-buildings, Chancery-lane, London.

19847. Improvements in electric fuses. Oliver Leopold Peard, 24, Southampton-buildings, Chancery-lane, London.

19852. Improvements relating to electric lamps. Willibald Felsch, 27, Chancery-lane, London.

19858 Improvements in electrical switches. William Sumner, 6, Lord-street, Liverpool.

NOVEMBER 6.

19877. Improvements in printing telegraph machines. Alfred Lyster Shepard, 8, West Kensington-gardens, Kensington, London.

19900. Improvements in and connected with electric punkah motors. Heinrich Spühl, 4, Corporation-street, Manchester. (Complete specification.)

19902. Improvements in joint-boxes for distribution of electric current from concentric or other cables. Francis Ernest Hammond, 115, St. Vincent-street, Glasgow.

19910. Improvements in or relating to overhead trolley wires or conductors for electric traction overhead electric cables or the like. Augustus Wyvill Hancock, John Leighton, and Robert Hacking, 111, Hatton-garden, London.

19922. Improvements in overhead electric fittings. Paul Traugott Julius Estler, and Franz Kleinsteuber, 52, Chancery-lane, London.

19934. Improvements relating to the mounting of electric bells. Charles Woittequand, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

19945. Improvements in incandescent electric lamps. William Phillips Thompson, 322, High Holborn, London. (Alf Sinding-Larsen, Norway.) (Complete specification.)

19948. Improvements in and relating to automatic switch systems for telephone lines. Johan Peter Pehrson, 322, High Holborn, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, April 10, 1900, being date of application in Sweden.)

19951. Improvements in or relating to dry-core cables and the like electric conductors. George Edward Heyl-Dia, 6, Lord-street, Liverpool.

NOVEMBER 7.

19987. An improved electrical connection or bond for application to railway or tramway rails. William Robert Sykes, Arthur Henry Johnson, and Charles Joseph Cooke, Winfrith, The Avenue, Bickley, Kent.

19988. An improved insulating rail joint for railways or tramways which offers considerable resistance to currents of electricity. William Robert Sykes, Arthur Henry Johnson, and Charles Joseph Cooke, Winfrith, The Avenue, Bickley, Kent.

19989. Telephone transmitter of the sounds of rifle fire, Maxim fire, pom pom fire, and Long Tom fire with the noise of its shell in progress and its ultimate bursting. Arthur James Cleland Jackson, Rathmore, Greenisland, co. Antrim.

20016 Improvements in and connected with switches or keys in electric lampholders. Hermann Oppenheimer, 55, Redcross-street, Barbican, London. (Actiengesellsch. fo Mix und Genest, Germany.)

20049. Improvements in the manufacture of elements or plates for electrical storage batteries. Jasper Myers Richardson and Harry Ramsbottom, 427, Strand, London.

NOVEMBER 8.

20110. A safety swinging arm for carrying overhead electric wires. Herbert George Thomas, 36, Greenwood road, Hackney, London.

20112 Induction electric telephony and telegraphy. John Robert Quain, Royal Colonial Institute, Northumberland-avenue, London.

20135. Improvements in the control of electrically-propelled vehicles or trains. Edward Henry Tyler and Arnold Greaves Hansard, 15, Kirkstall-road, Streatham-hill, London.

20139. Improvements in automatic telephone switches. Johan Peter Pehrson and Gotthilf Ansgarius Betulander, 322, High Holborn, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, April 12, 1900, being date of application in Sweden.)

20146. A sound-strengthening appliance for telephone stations. Franz Oprendek and Louis Röder, 4, South-street, Finsbury, London.

NOVEMBER 9.

20152. Improvements in or relating to magneto electric and other ignition devices. John Ridley and George Gibson, 18, Cavendish-street, Birkenhead.

20177. Commutator or collector for electrical purposes. Emile Batault, 21, Ely-place, Holborn-circus, London.

20179. Improved construction of electric arc lamp. Eric Rivers Smith, John James Rathbone, and Charles Bean King, jun., 166, Fleet street, London.

20186. An improvement in air-brakes controlled electrically and by air pressure. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktiengesellschaft, Germany.) (Complete specification.)

20197. Improvements in the construction of metal troughs for laying electric mains. Maurice Lachman, 6, Bream's-buildings, Chancery-lane, London.

20200. Improvements in or relating to electrolytic cells. John Hall Noble and Alfred Merry, 6, Lord-street, Liverpool.

20201. Improvements in or connected with apparatus for covering electric conductors with insulation. George Edward Heyl-Dia, 6, Lord-street, Liverpool.

NOVEMBER 10.

20231. Improvements in electrical connections. Robert Frederick Hall, 24, Temple-row, Birmingham.

20255. A new or improved fitting or accessory for electric ceiling roses and the like. William Grimshaw Stones, 55, Market-street, Manchester.

Digitized by Google

20256. Improvements in or relating to swinging brackets for electric lights and the like. Alfred Julius Boult, 111, Hatton-garden, London. (K. M. Seifert und Co., Germany.)

20264. Improvements in connections for electric mains. Charles Douglas Burnet, 24, Southampton-buildings, Chancery-lane, London.

20277. Improved means for supporting the osmium filaments of electric incandescent lamps. Oliver Imray, Birkbeck Bank chambers, Southampton-buildings, Chancery-lane, London. (The Oesterreichische Gasglühlicht-und Electricitäts-Gesellschaft, Germany.)

20285. Improvements in chains for suspending electroliers, electric lamps, and the like. Edwin Fletcher, 5, Corporation-street, Birmingham.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Dec. 1.

1899.

23753. Maximum electrical current indicators. Rimington.

24459. Electric telegraph apparatus. Dearlove and Brown.

24942. Electric brakes. Tingley. (Date applied for under International Convention, May 18, 1899.)

25299. Electricity meters. Johnson.

1900.

164. Electric incandescent lamps. Stead and Carr.

182. Electric ignition devices for internal-combustion engines. Northey and Electric Motive Power Company, Limited.

630. Method of and apparatus for connecting electric meters in three-wire circuits. Dick and Reason Manufacturing Company, Limited.

659. Electric switches. Gardy.

1704. Electric alarms. Mills. (Vial.)

1906. Electric pendulum clock. Haenichen and Haenichen.

2282. Dynamo-electric machines. Dalén and Hultqvist. (Date applied for under International Convention, July 7, 1899.)

5710. Indicator for storage batteries. Tiddeman.

6261. Electric switches and resistances. Atkinson.

7759. Electrically-operated submarine working devices. De Pauer and de Kutschera.

9751. Switches for electric tramways on sectional conductor and like systems. Eyre.

13966. Roentgen-ray tubes and other vacuum tubes. British Thomson-Houston Company, Limited. (Thomson.)

14104. Electrodes for use in electro-chemical processes. Lauckner. (Vogelsang.)

15721. Telephone systems. Cedergren and Piltz.

16702. Dynamo-electric machines. British Thomson-Houston Company, Limited. (Rice.)

16706. Means for preventing hunting of dynamo-electric machines. British Thomson-Houston Company, Limited. (Buck.)

16945. Electric igniters for explosion motors. Ricard and Gary.

NOTES.

Institution of Electrical Engineers.—We are informed that the Dublin section of the Institution of Electrical Engineers will hold a conversazione on the 29th inst. at the rooms of the Royal Dublin Society. This conversazione is to take the place of the meeting which was announced for the 22nd instant, and which has been postponed.

Society of Model Engineers.—The eighth monthly meeting of the Liverpool branch of the Society of Model Engineers was held on the 7th inst., when a general discussion on compound engines, etc., took place. The next meeting is to take place at the Balfour Institute, Liverpool, on Dec. 5, when a lecture will be given on model boilers. The hon. secretary of the Liverpool branch is Mr. F. T. Stewart, of 14, Adelaide-road, Kensington, Liverpool, from whom all necessary particulars may be obtained.

The Philippine Cable.—We notice that it is stated by Reuter's correspondent at Washington that President McKinley will recommend to the Congress that justice be done to the British Cable Corporation's claim for indemnification and substantial recompense for damage suffered through the occupation of the Philippines, and to the claims of the Manila and Dagupan Railroad Company. The United States Attorney-General has held that both companies have equitable claims. There has been a good deal of correspondence on the subject, the British authorities earnestly supporting the claims of the British subjects interested.

An Electric Log.—An interesting application of th use of electricity in navigation is the electric indicatin log of a new type, which was recently given a trial ogthe United States torpedo boat "Porter." It is the invention of Captain A. N. McGray, of Boston, Massachusetts, and consists of a small propeller trailed after the ship by a long cable containing two insulated conductors. The propeller operates a train of mechanism which periodically closes an electric circuit. An electromagnet on board the vessel advances the indicating mechanism step by step with the closing of the circuit. The instrument tested registered to twentieths of a mile, and is said to have given results correct to one-half of 1 per cent. on a trial run of 44 miles.

Waterford Lighting.—The Corporation of this old and important town in Ireland have decided to apply for an electric lighting provisional order, and are considering the advisability of the introduction of water power. We gather from a report in one of the local papers that the River Clodagh at Portlaw used formerly to work mills, and that the Waterford Corporation hope to be able to get rights for this water power. Without a knowledge of the district it is, of course, impossible to discuss the feasibility of the scheme, but the Corporation will not find it economical to lay down large works for the use of water power unless there is a regular flow and a considerable head. We wish the undertaking every success.

The Late Mr. G. J. Symons, F.R.S.—At a meeting held in May last to consider the question of a memorial to the late Mr. G. J. Symons, the distinguished meteorologist, and founder of the British rainfall organisation, it was resolved unanimously that the memorial should take the form of a gold medal to be awarded from time to time by the council of the Royal Meteorological Society for distinguished work in connection with meteorological science. An executive committee was appointed to take the necessary steps to raise a fund for that purpose, and their appeal has, we understand, been very heartily responded to. The committee have decided to keep the list open until the end of January, 1901, in order to allow all who wish to contribute to the memorial fund.

Hooligans.—We hear a considerable amount just now as to the doings of what Londoners have been pleased to term "Hooligans." It appears, however, that London is not the only place in which trouble is experienced from persons who use violence in order to attain their ends. Thus, in Paris, on the electric tramway, one recent evening, some six or eight men are stated to have jumped on a car on its arrival, and commenced to attack the conductor in order to take away his money satchel. He, however, used a crowbar to some purpose, and the thieves left him alone. Instead, however, of clearing off, they then entered the tramway office and attacked the man in charge, who was alone. This man would have been killed but for the arrival of the police, who captured three of the band after a severe struggle.

An American Patent.—Another case of the curious awards given by the American Patent Office is brought to our notice in the *Electrical World* in connection with a patent recently granted to Mr. E. W. Rice, jun., for a means of transforming polyphase currents into direct. The object of the so-called invention is to permit the current being used for feeding three-wire or kindred systems. When one looks into the arrangement patented, one finds that it consists in using each single phase of the three-phase system independently. The energy is transformed down by independent transformers, and then converted into direct current by independent rotary converters. For this combination Mr. Rice has been granted a patent. We should much like to see the expert opinion of the United States Patent Office on the novelty of the combination. It seems to us to be new neither in detail nor in combination.

"The Street Railway Review."—Following on the same lines as on a previous occasion, the *Street Railway Review* during the recent meeting of the American Street Railway Association at Kansas City published a daily edition, there being a number for each of the four days. These daily editions contained the programme of the proceedings to be followed during the day, and a practically verbatim report of the proceedings and discussions of the previous day. Chatty descriptions of visits to works and small numerous paragraphs dealing in more or less remote ways with street railways were also given. The idea is in our opinion a very good one, and supplies a want which is always felt to a certain extent in connection with long meetings lasting for a week or so. The daily editions do not take the place of an ordinary number, but form a very useful supplement to the whole volume.

Tramway Shares.—We have received a circular from a syndicate who, by its title, professes to deal chiefly with rail and tram shares. The circular states that the syndicate wishes to purchase certain electrical tram shares in small amounts. Amongst the companies mentioned, there are some old-established ones whose shares are easily obtained on the Stock Exchange, provided that the would be purchasers are prepared to pay the usual market rates. It would be no advantage to the shareholders to sell these shares to the syndicate in question, as it offers for them a lower price than can be obtained in the open market. One is inclined to question whether the shares demanded are actually required or whether the syndicate wishes it to be known that it is prepared to deal in them. In any case it is difficult to see why it pays to circularise the whole profession and others in order to get hold of some £400 or £500 worth of stock. The conclusion would appear to

Digitized by Google

be that it pays in such matters to deal through recognised channels.

The Electric Testing of Meters.—At last an arrangement has been come to as far as the City of London is concerned with respect to the testing of electric meters. A new outfit is to be obtained, and placed under the care of Mr. A. A. Voysey, the City electrical engineer. The expenses of the department will be contributed to by both the electric lighting companies having works in the City, each having agreed to provide £200 per annum for the purpose. It is not proposed at present that all the meters to be used on the City circuits are to be tested by Mr. Voysey before they are installed, but rather that he should act as electrical inspector when any consumer has doubts as to the accuracy of the reading of his meter. We believe that, subject to the approval of the Board of Trade, he may also have a voice in the type of meters to be installed by the companies, insomuch that he will be able to condemn all those which, after a few months' trial, do not give satisfactory results.

Electric Lighting in St. Marylebone.—The new Borough Council of St. Marylebone propose to hold a special meeting on Dec. 20 in order to approve of a proposal that an application should be made for an electric lighting provisional order. We presume that, in order to comply with the provisions of the Electric Lighting Act, the Council will have to advertise now their intention to apply, as it will be too late after the meeting to give the necessary notices to the Metropolitan Electric Supply Company. We fail to see in what respect the new Council is entitled to an order which was not granted to the old St. Marylebone Vestry, unless they are quite prepared to buy out the present company, and only come before Parliament in order to draw attention to the high price asked for the purchase of the works within their area. In any case we hope that the electric lighting policy of the new Council will be decided in December next, and that it will be carried out with a firmer hand than was displayed by the Electric Lighting Committee of the old Vestry.

Japanese Railway Building.—The *Electrical Friend*, in one of its recent issues, contained an illustrated description of various plant which is being used in connection with the construction by the Government of the new central steam railway. In constructing this line a mountain called the Sasso Toge is to be bored through, and special power plant has been ordered for carrying away the rocks which will be excavated in the making of the tunnel. The tunnel is to be some three miles in length. The power plant consists of a 46½-h.p. Leffel horizontal turbine with an 80ft. head, and which is provided with Replogle's mechanical governor. The dynamo is a 45-kw. 500-volt Westinghouse machine, running at 850 revolutions, the locomotive being also of Westinghouse construction. It consists of a double-motor truck provided with two 15-h.p. motors. The draw-bar pull is 1,500lb., and the gauge of the road about 30in. Some 6,549lb. can be carried in one train, and the line is said to be doing excellent service. The lighting also of the tunnel is effected by electricity, and for this purpose there is installed a 16-h.p. turbine, driving a 15-kw. dynamo.

The Alternating-Current Arc.—Mr. C. Wiley recently read before the Chicago Electrical Association an interesting *résumé* on the action which goes on in the alternate-current arc lamp. The main object of the paper was to explain the reason why the enclosed alternate-current arc is not so satisfactory as the direct-current enclosed arc. That this is so everyone knows who has tried to obtain from electrical manufacturers a really reliable enclosed alternate-current arc lamp. The reason for the instability of these lamps is considered by Mr. Wiley to be the great resistance of the carbon vapour between the two extremities of the carbons. The current, of course, is reversed twice in every alternation, and with this great resistance it falls to zero almost as soon as the current begins to fall. Hence during the larger part of the cycle the current is zero, or has a very small value, and the arc tends to extinguish. The author then goes into the question of the influence of a core in the carbons used for the alternating arc, and shows that if the core consists of a mixture of certain chemical salts the resistance of the arc is decreased, and a much more steady result is obtained. Another point of interest is that the author shows that it is much more advantageous to have a small inductive resistance in series with the arc than an ohmic resistance. This is so because the E.M.F. of the former will help the lagging current over the zero or dead centre of the arc.

The Caledonian Electric Power Company.—The above is the name of a new company which is to be incorporated under the Private Legislation Proceedings of Scotland Act of 1899. The object of the company is—as its name discloses—to do with the distribution of electrical energy. The area which the company proposes to work includes the large manufacturing district on the West of Scotland, comprising the whole of the county of Renfrew, a portion of the county of Lanark, and portions of the counties of Dumbarton, Stirling, and Ayr. In fact, the company proposes to act on much the same lines as those companies which obtained powers last year for the production and distribution of power in bulk in Lancashire, Durham, and South Wales. In order to avoid undue complication, the city of Glasgow is excluded from the operation of the scheme. In this, the most important area of Scotland from an industrial point of view, there should be a great opening for cheap electrical energy. It will be interesting to see when the Bill comes before the House of Commons as to whether the promoters have succeeded in obtaining any water-power rights, or if they will be obliged to depend wholly on the energy produced by the burning of coal. We are informed that Messrs. Maclay, Murray, and Spens, of Glasgow, are the solicitors, and Mr. A. A. Campbell Swinton, M.I.C.E., of 66, Victoria-street, Westminster, the engineer to the scheme, which is said to have the support of leading manufacturers of the district.

Rubber.—The imports of raw rubber into Liverpool, we gather from the *Liverpool Journal of Commerce*, reached during the 12 months ended June 30 last a total of some £6,000,000. Raw rubber being, however, a rather dear commodity, the £6,000,000 represents a comparatively small tonnage, the value per ton ranging between £280 and £500. The tonnage actually delivered during the year amounted to 10,437 tons of Para rubber and 6,977 tons of mediums, totalling altogether 17,414 tons. This total, although it appears to be small, is more than half of the total arrivals in Europe during the season, these European arrivals amounting to 30,194 tons, and it was also but little short of the total arrivals in the United States ports, these being 20,883 tons. The world's approximate total production of rubber for the whole season of 1899-1900 was 53,348 tons, so that the deliveries in Liverpool were nearly one-third of the world's estimated production. The landings of rubber in London do not approach to anything like the tonnage of the Liverpool imports. The importation of the year's tonnage into Liverpool, the warehousing, handling, etc., provides work for a large number of persons, there being at present some 14 firms in Liverpool in the rubber trade acting either as importers or consignees. This growth of tonnage shows a healthy state of the trade, and

Digitized by Google

an increasing value of the trade to Liverpool, as most of the Para rubber shipped eastwards comes to this port, and it will be gratifying to those interested in the port to note these facts of the extent and growth of the indiarubber trade.

The London Streets.—With the outcry one sees in the daily papers about the state of the London streets, one usually finds at the end of the editorial comments that in a few months' time the work as far as the City is concerned will be completed. It has, however, begun to dawn on the minds of a few persons that even when the telephone conduits are laid, there still remain to be placed in the public streets the mains of the Charing Cross and Strand Corporation. We notice that the engineer of the Post Office has been interviewed on the question of interference with the streets, and he excuses a certain amount of the inconvenience on the ground that this electric lighting company is partly responsible. For instance, in Fleet-street up to the present practically no telephone ducts have been laid, but there has been a considerable interference with the traffic for the past three months. Now that the street surface is down again, the Post Office are commencing at the upper end to open it up for the telephone conduits. It would surely be much preferable to have the two obstructions at the same time, and to close the street to through traffic. As it is at present, the average speed of the vehicles passing through the street is so small that it is practically useless to all but the heaviest goods traffic. It is not pleasing to contemplate that this interference is likely to go on for another year at the very least, and we shall be surprised if the electric lighting company in question will have completed the work by that time. As we pointed out when the order was granted, we very much doubt if the gain from competition in electric lighting is worth the great waste of time and money entailed in laying a complete new system of electric lighting conduits throughout the length and breadth of the City.

Electrical Towing.—We have mentioned before that on certain of the canals of Germany towing by electricity is being brought into use. We now notice that the New York untechnical Press are commenting on the fact, owing to their consul at Frankfort having sent in a report on the matter. Thus it is stated that a number of experiments have been tried on a short section of the Finow Canal, on the route between Berlin and Stettin. This canal is traversed by 25,000 boats in each direction annually, or 100 boats a day for eight months out of the year. The portion of the Finow Canal selected for the recent tests included several sharp curves, and at least one railway bridge, so that it might present most of the serious difficulties likely to be encountered in this class of work. A small electric locomotive like those used in America for switching purposes was employed, and a track was laid for it on the towpath. The motor weighed about two tons, was 6ft. 10in. long and 1ft. 10in. wide, and derived its current from an overhead wire, like a trolley car. The machine was capable of developing 15 h.p., which was more than was required. The track had a gauge of 3·28ft. One rail was much heavier than the other, one weighing 18lb. to the yard and the other 9lb. The heavier rail was the outermost, or furthest from the canal, and on it rested four-fifths of the weight of the motor. The same rail served also to convey the return current. Most of the track was laid at the level of the towpath, part of it on sleepers and partly on blocks of concrete. But at one point for a few rods the track was carried on a wooden structure, 9½ft. above the towpath. Posts 12in. square and 18½ft. apart were connected by longitudinal cap pieces, on which the heavy rail was laid. The other rail was carried by a stringer supported on brackets. The conductor was an 8mm. copper wire, the poles for which were from 100ft. to 132ft. apart. The boats on the Finow Canal are barges capable of carrying from 150 to 175 tons. A few have a length of 132ft. and a beam of 15½ft. The consul reports that "these experiments showed the system to be capable of meeting all needs, working, as it did, with safety and economy."

The Nernst Lamp.—A great deal has been written from time to time concerning the structural evolution of the Nernst lamp, but reliable data as to the commercial efficiency of the most recent form of the lamp—*i.e.*, that exhibited by the Allgemeine Elektricitäts-Gesellschaft at the Paris Exhibition—are very slow to leak out, whence it may be adduced that its practical success is not yet. We had occasion to refer in a recent issue to a beautiful souvenir issued by the company in question of their extensive exhibits at the Exhibition. This souvenir contains some interesting general information about the lamp, but we were disappointed in finding no mention of its prospects of commercial success, though it affords some consolation to know that our German contemporaries are little better informed in this respect, and, indeed, join in giving expression to the above complaint. For the time being, then, it seems we shall have to content ourselves with general information, and even of this little fresh has transpired. Considerable importance is, however, attached to the invention, especially by the Allgemeine Elektricitäts-Gesellschaft, who have devoted a large floor space at their Berlin works to its evolution and manufacture; and if ultimate success from a commercial point of view is at all within the bounds of possibility, we may rely upon this firm to obtain that success. Lamps suitable for pressures of 110 and 220 volts, and of 25 c.p., 50 c.p., and 100 c.p. are being made, we understand, while experiments with lamps of greater power are in progress. Since the Nernst lamp consumes 1½ to 1¾ watts per candle-power, it follows that the consumption of energy for a given intensity of light will be only about half as great as would be the case with the ordinary type of incandescent lamp. This advantage is, however, partially eliminated by the relatively short life of the Nernst lamp, which has hitherto attained to but some 300 working hours. No authentic data as to the molecular change of the incandesced material and the decreased illuminating power thereby involved is yet available, but in this respect an advantage is undoubtedly obtained, in that the Nernst lamp retains two-thirds of its original value after it has become unserviceable. Further developments of the lamp are awaited with interest.

The Telephone Service in Chicago.—We gather that great interest has recently been aroused in Chicago by the Chicago Bell Telephone Company undertaking to instal public and private telephones on a call system at a uniform rate of 2½d. per call. These installations will be on what are known as party lines, or, in other words, 10 subscribers will have the use of a common line wire, and it will hence not be convenient at certain times of the day owing to the fact that a number of subscribers on these line wires will be wanting to use their instruments at the same time. The guarantee which is to be required before these instruments will be installed will be two calls per day for offices and one call per day for residences. If these numbers of calls are not made, the subscriber will have to pay the difference at the end of the month. While knowing that the value of money is rather more here than in the States, the price does not seem to us to be remarkably cheap. Of course, with it a subscriber might be able to get his telephone in a private

Digitized by Google

house for £3. 16s. per annum, but the service would be by no means the best possible, and we hope in this country to get an individual line for very little more per annum. The instrument being used in Chicago provides for the insertion of the toll in a slot in the subscriber's machine, and in the event of a call not being possible, the money is returned by the closing of a circuit by the operator at the exchange. A very large number of new subscribers is expected in consequence of this new service. We notice in connection with this service, as described in the *Electrical World*, that there is in the same issue a *résumé* of the various improvements which have been tried with varying success for recording the number of messages sent by a given subscriber. In the first class of these instruments the counter is placed on the subscriber's premises, and is controlled by the operator at the exchange. When a call which moves the counter through one division is given, the subscriber hears a signal, and knows that a record of the call has been made against him. In the next class the meter is placed in the exchange and is operated either by hand by the switchboard operator or automatically by means of relays in connection with the circuit. In the third system duplicate registers are made on the subscriber's premises and at the exchange. The fourth system is also described as only on the subscriber's premises, and is worked by the subscriber, who presses a button. This gives the operator at the central exchange the signal, and also registers the call, the connection being made in the usual way.

The Telegraphone.—The wonderful inventor who has under various names found his way of late into the daily Press has reappeared again under the guise of the inventor of the "telegraphone." This instrument, as might be expected from its name, is going to be an automatic recorder of messages spoken into the telephone. To Herr Poulsen belongs the glory of the invention, in which he employs, we gather from the *Daily News*, a microphone transmitter connected to a battery of two or three dry cells and an electromagnet of a peculiar shape, which takes the place of the ordinary telephone. The electromagnet, in fact, is said to be a telephone without the vibrating plate. Instead of an iron plate vibrating over the pole of the electromagnet, a steel wire travels past the pole in such a way that the magnetism excited in the pole of the electromagnet by the varying current induces a corresponding magnetism in the wire. To this end the electromagnet is made very small, no bigger than a nutshell, and it has two poles inclined to each other, so that the wire passes between them, and is magnetised on two sides. The wire is about $\frac{1}{8}$in. thick, and it is remarkable that the magnetism produced in it is localised in a very definite manner. The wire is wound spirally on a drum or cylinder which revolves, and the electromagnet travels along the cylinder from one end to the other as it revolves, thus bringing the whole length of the wire past the pole of the electromagnet, to receive its charge of magnetism. In this way the varying electrical current of speech from the microphone makes its magnetic record on the wire. So much for the record, but in order to get the record to reproduce the original sounds the process must be reversed. The magnetism of the wire as it moves past the pole is then to induce magnetism in the pole, and in doing so excites an electric current in the bobbin of the electromagnet. This induced current varies in strength with the magnetism in the wire, and consequently reproduces the original sounds in the receiving telephone, which, of course, is held to the ear. The inventor says the magnetic record will persist for a year, and give over a thousand repetitions of the message. It can also be "rubbed out," and the same wire used over again for other messages, this being done by sending a constant current through the electromagnet and passing the wire before its pole. Herr Poulsen proposes by a similar instrument to deliver news to a number of clubs or exchanges. It is further stated that Herr Pedersen, a collaborator of Herr Poulsen, has devised a "duplex" method of recording two messages on the same band or wire, but it is kept a secret for the present. It is a pity that Herr Poulsen cannot invent another machine which will do away with the necessity of going to the telephone at all, but which would answer any queries which might come automatically. Such an instrument would appear to us to have more chance of success than the present arrangement.

Cathode Rays.—In the current issue of the *Physical Review* is a long article contributed by Messrs. E. Merritt and O. M. Stewart on "The Development of Cathode Rays by Ultra-Violet Light." The authors made several experiments with an apparatus consisting of a vacuum tube with the cathode at the bottom and three electrodes at the top. The cathode was connected with the negative terminal of a dry battery. Immediately above the cathode was the anode, consisting of a ring of aluminium wire. In order to admit the ultra-violet rays into the interior of the tube, a quartz plate was mounted on a side tube. The ultra-violet light which fell on the polished zinc cathode came through the quartz from a spark between zinc terminals. From experiments with this apparatus the authors state that it is clear that the effect of a magnetic field is to produce a deflection of the photo-electric rays. The path followed by the escaping charge is altered, while its amount remains practically unchanged. Three tables are given, showing the effects with a magnetic field direct, with the magnetic field reversed, and with a very strong field direct. In the first case the maximum effect was obtained, but with the field reversed the charge rate diminished instead of increasing as at first. In the third case with a strong field the charge rate was reduced nearly to zero, instead of being increased. The experiments prove to the authors' satisfaction that photo-electric rays are magnetically deflected. As to the source of the formation of the photo-electric rays, this can still only be regarded as unknown. It is the same, with certain important differences, with ordinary cathode rays. The following way of looking at the matter, however, is thought to be sufficiently plausible to deserve consideration. Thus, assuming first that the primary effect of illumination is to cause the development of cathode rays, and that these rays are produced not only at low pressures, where it has been possible to detect them directly, but also under ordinary atmospheric conditions, remembering that the rays make the air a conductor, it is seen that the photo-electric current will, in general, consist of two parts—viz, the current carried by the photo-electric rays themselves, and the current carried by the ionised air. At high vacua practically the whole current will be carried by the photo-electric rays. But as the pressure of the surrounding air increases, the rays will be more and more completely absorbed, and since this absorption results in ionisation, the conduction current through the air will become more important. At atmospheric pressures the rays are probably absorbed in the immediate neighbourhood of the charged surface. In this case the discharge is almost wholly carried by electrolytic conduction, but since the ions are developed very close to the surface, the case differs essentially from that of the ionisation produced in gases by other causes. In most cases both positive and negative ions are present throughout the gas. But in the photo-electric discharge the positive ions pass at once to the cathode and are destroyed.

The American Automobile Club.—The first annual exhibit of the Automobile Club of America was opened on the 3rd inst. at Madison-square Garden, New York. In spite of the counter-attraction of the election parades, there was a very fair attendance at the show. The grounds were very carefully laid out, and had a track constructed round the arena upon which the automobiles could be run. In order to show the climbing powers of the automobiles a track was erected which had a very steep grade. This runway was 200ft. long, and at the highest point 53ft. above the floor. It was 8ft. wide and laid on scantling. It was built in four sections, these being stated to be running from 20 per cent. grade up to 43½ per cent. Amongst the exhibits we notice a novel arrangement shown by the General Electric Company. This was an electrical hydrant, designed to be used by electric vehicles that are in need of replenishing their batteries. The hydrants are to be placed at convenient points, and are operated on the "penny-in-the-slot" principle. When a vehicle needs a charge, all the operator has to do is to run up to the hydrant, put a suitable charging plug in one of the four receptacles designed to receive it, and then drop a quarter-dollar piece in the slot and wait. There are four receptacles, each of which is numbered. No. 1 represents a charging current of 20 amperes, No. 2 a charging current of 30 amperes, No. 3 a charging current of 40 amperes, and No. 4 a charging current of 50 amperes. Provision is made by means of a push button by which the charging plug can be taken out of any one receptacle and placed in any other without cutting off the current supply paid for. The supply is about 2·5 kilowatt-hours, and when this has been furnished the current is automatically cut off, and no more can be obtained until another 25-cent piece has been put in the slot. In connection with this charging hydrant, or "electrant," as it is called, an interesting point is that of the eight makes of vehicles exhibiting but three used charging plugs and receptacles that were similar. The other five used specially-constructed plugs, each of a different design, and none of which could be used in the receptacles provided in the hydrant. It would, therefore, seem as though there were need of standardisation in this matter, and that all electric vehicles should have a standard charging-plug receptacle fastened somewhere in circuit. This would eliminate the necessity of providing several different styles of charging plugs at the different charging stations. In connection with this exhibition the *Electrical World* comments unfavourably on the practice which some manufacturers indulge in of claiming a much greater mileage capacity for their vehicles on one charge than they can accomplish under ordinary everyday conditions. In this way the would-be purchaser is misled, and if he buys he is disappointed with his purchase. The dissatisfaction which he feels with his vehicle will probably become communicated to his friend, who will be very careful as to buying electrical vehicles manufactured either by that particular maker or by any other. Many instances of this kind might have a very bad effect on the development of the automobile industry in any particular district.

Electric Traction in Italy.—We notice in the *Electrical Review* of New York a description of the electrical equipment of the Lecco, Sondio, and Chiavenna line in North Italy. We have referred to this line in previous issues, but a few additional details may be of interest. The length of the line upon which electric traction is used is about 66 miles, with a maximum gradient of 22 per cent. In summer the line has very considerable passenger traffic, but at other times also there is a steady freight traffic. In order to serve both interests the service has been organised along the following general lines: the complete separation of passengers and freight traffic; a complete distinction in make-up and schedule between express trains running over the line from end to end and trains for local service; designing the trains with a capacity sufficient for expected needs by increasing in advance both the number and weight of trains in service. The passenger trains are drawn by an electric locomotive of about 300 h.p., and weighing about 50 tons. This vehicle can carry 60 passengers and two tons of baggage and draw four ordinary cars behind it at about 37 miles per hour on grades up to 10 per cent. Freight trains are drawn by locomotives of 700 h.p., capable of drawing 250 tons up a 10 per cent. grade at a speed of 19 miles per hour. The system difficulties of the long-distance electrical transmission have led to the adoption of the three-phase high-tension current, both for general transmission and for distribution to the motors on the trains. The current for operating the plant will be generated directly at 20,000 volts at the water-power station at Morbegno, 10 miles from Colico, from which it is led by a three-conductor overhead line, using copper wire 7mm. in diameter, to 12 sub-stations situated along the line at distances of just over six miles apart. These sub-stations reduce the tension to 3,000 volts, and the current is distributed at this pressure to the motors by means of two trolley wires 8mm. in diameter, the track being used for the third conductor of the three-phase system. The two trolley wires are suspended 18½ft. above the track, except in the tunnels, where the height is 14ft. In the power station at Morbegno are four units, consisting of a turbine and alternator, direct coupled together, of 2,000 h.p. The water-wheels are of the usual type, and are provided with auxiliary power governors. The alternators have rotating fields and generate at 20,000 volts in each phase, and have a frequency of 15 cycles per second. Current is taken from the line by two aluminium rollers, these having a diameter of 3in. By means of a collecting brush running on a graphite collar, current is taken from each roller, and passes, by means of a highly insulated cable, directly to the primary windings of the principal motors. Short-circuits between the conductors of different phases at switches or junction points are avoided by arranging the contact rollers on a slant. By this arrangement much complexity is avoided, the overhead structure in no case weighing more than 180lb. complete. The 3,000-volt current connection to the motors is protected by metallic tubing surrounding the cables carrying it, these being connected with the ground. The primary winding of two of the four induction motors on the car are directly connected with the contact roller, and their two secondaries or rotor circuits may be connected either to a liquid resistance or to the primary circuits of the other two motors with which the car is furnished. In the secondary circuits of the latter are inserted variable resistances. If the four motors are coupled two by two in series the velocity of rotation of the two rotors will be practically half that of the primary rotating field, and also half that which the two primary motors would attain if fed directly from the line. This arrangement gives two running speeds of 37½ and 18½ miles per hour, but in order to avoid abrupt passage from one to the other, a liquid rheostat is inserted into the secondaries, giving an adjustable resistance. Line switches have been arranged so that shunting may be done with the electric locomotives at stations. The first of these vehicles has recently been tried, and the tests made at a speed of 53 miles per hour were successful. It is hoped that the line will be in working order by the spring of 1901.

PRACTICAL NOTES ON ELECTRIC MAINS.

BY A MAINS ENGINEER.

1. *General, and the Management of Men.*

In the following notes it is not proposed to discuss at all the various methods of distribution as to their respective merits or as related to generation, the question of method being generally settled beforehand either by the consulting engineer or the resident engineer, and one in which the mains engineer is not asked for his advice, but has practically to do as he is told. But there are many points on which the chief engineer consults the mains engineer during the running of an installation, or on extensions. It is with a view to assist the mains engineer in such consultations and in his routine work that these notes have been compiled. The text will include cable laying and jointing, cable testing, sub-stations and sub-station gear, house connections and installations, and street-lighting. Attention will in many cases be paid to detail, and mains engineers will find that it is only by such attention on their part that they can hope to lay down a system of mains which will give them the least amount of trouble after completion, and which will insure them against night calls, things not at all to be desired after a worrying day's work.

There is no doubt that electric mains have not had their fair share of attention hitherto. There has always seemed to be a tendency on the part of consulting and chief engineers to relegate the mains to a secondary place, and to give their best efforts to the generating plant. But surely it is necessary for good results that the mains should be as perfect as the generators. A most important point for the mains engineer is that he should as far as possible aim at making a permanent job at the start, so that the work has not to be done over two or three times. He is very often hampered in this way through promises which are often given by committeemen and sometimes by chief engineers to intending and worrying consumers, but a little forethought during previous work and to the general area of proposed supply will save much of the temporary and rushed work which so often obtains. In addition to this view of temporary work there is the question of expense, which is an important one, if only to the chief engineer.

A most important item in this question of temporary work is the reopening of streets for the laying of extra cables or larger cables. To cut down initial capital cables are not estimated for which everyone knows will have to be laid, probably before the expiration of a year, with the result that the poor, unoffending mains engineer has to bear the burden of the outraged shopkeeper's maledictions. The mains engineer should therefore, at any opportunity, suggest as to the size and number of cables. Of course, he will probably be met with a remark to the effect that the money is better in the bank than lying underground in the form of copper. But in municipal districts it is no bad tip to keep the mind of the shopkeeper quite calm, as, from experience, he will cheerfully pay his lighting bill, if only the corporation do not block his shop-front. Also, in an alternating system, the initial size of transformers is another matter worthy of notice, as often the transformers first put down are overloaded before the second winter, entailing much labour to lift out of the ground and to replace with larger, including the alteration of many connections and the scrapping of much cable, introducing also, to however small an extent, a certain amount of unnecessary risk to life on the part of the jointer, and, finally, the selling of the small transformers at a considerable loss.

Turning again to the question of attention to detail, personally, on the part of the mains engineer, it is a good plan on the smaller undertakings for the mains engineer to act somewhat as foreman, thus keeping himself thoroughly in touch with all that is done. This plan, however, cannot be carried so far on a large system; much has then to be left to the foremen, and even to the workmen. Seeing that this is the case, how necessary is it then that the mains engineer should thoroughly understand the management of his men. This is so both in the case of the small and the large undertakings, but much more vital in the latter. The mains engineer must, above all, be firm in his dealings with the men—that is to say, when he gives an order he must see that it is carried out, and in his way. If he makes a rule he should not break it unless under very exceptional circumstances, and then only after pointing out these circumstances to the person in whose favour the rule has been broken. Smoking and drinking should at all times during regular working hours be definitely vetoed. Smoking, however, should be allowed during the working of overtime.

The one great thing in the management of men is to beget confidence; show them that you trust to them, and also let them see that they can confide in you. Although the engineer is firm, he can still, to a large extent, sympathise with his men. He can hear their troubles and often give good advice, which is most thankfully received, as a rule, by them. And in any case of supposed wrong-doing which arises the engineer must not give way to rash judgments, but must try to look at the case from the man's point of view, and remember that the lives of his men are not always the rosiest, and give his judgment accordingly, always trying to smooth over obstacles, and, however little, to elevate the mental position of the men. It is also a great mistake to be stingy with wages, as an extra halfpenny per hour means very little at the end of a year, and on well-managed jobs most of it goes down to capital account, so that at all times a good man should rapidly be advanced to the top rate of pay.

During the working on repairs to breakdowns, the men often have to work many hours at a stretch. In cases of this sort, it is imperative that they should be allowed time to get full meals, as nearly as possible at their regular hours. It is this attention to the men and their personal comfort that will go far to procuring good work, as they then feel themselves to be necessary units to the good working of the thing, and the details before mentioned will so be properly attended to by the men themselves. It will also be found that if the men do make a mistake or have an accident with their work, they will immediately inform their engineer, knowing that they will get justice from him; and they will never attempt to hide anything. The engineer will find that if he follows in these lines his management of his men, on his leaving one berth for another his men will nearly always want to follow him—a certainly good state of affairs for the departing assistant, but not usually liked by the chief.

The judicious selection of men and their training so as to be quickly useful is another point which requires careful attention on the part of the engineer. The taking on and discharging of men cannot be left to a foreman if harmonious working is desired, as in nearly all cases the foreman makes favourites and is down on other men, for various reasons which do not bear looking into. Many an excellent man has had his career nearly spoilt by some unreasonable dislike which the foreman has taken to him, and has only been saved through the fact that the engineer has had his eye on the man, and has enquired into the reason of the foreman's dislike. A new job is usually started, as far as mechanics are concerned, by borrowing from the cable makers, and some of these men prefer to stay in the town to which they have been sent. It then becomes necessary to provide them with mates. It is in providing these mates that a little care is required. As a rule, boys have been found to be almost useless—they certainly are useless as jointer's mates, as they are not strong enough to open ground—thus a third person is required to do this. It is obvious, then, that a jointer's mate should be, at any rate, nearly a man. In selecting a man for a jointer's mate, he should be selected for strength, and if he has been a navvy so much the better. He should also look fairly bright, but he should certainly have no preconceived ideas as to his own fitness because he has been used to tinkering in some other line. Such a man will not care about using pick and shovel, and will be a perpetual worry. It is far best to train a man from perfectly raw material: he will then always do as he is told. It will then be best not to employ youths under 18 years of age if it is expected that they should earn their money, and even so young they would be better sent with, say, a meter fixer. Apprentices are a side issue of the question, and they should be left severely alone on municipal jobs, leaving them to the cable firms, to whom they are useful in many ways. A good mate so selected should make a fairly good jointer for low-tension work in from two to three years, and can afterwards be slowly advanced to the position of high-tension jointer.

One of the hardest tasks a mains engineer has to perform

Digitized by Google

is that of selecting a foreman. In the training of their young men, it might be as well that the employers—corporations or supply companies—should insist on the men going to a night school for technical training at least for two evenings a week, the employers paying the fees. A small well-selected library of elementary text-books might also be advantageously kept for the use of the men. Amongst other subjects which the men should be induced to take up is the subject of building construction. Scarcely one electrical man in a hundred knows anything about it, and yet it is of the utmost importance. As soon, then, as it is possible to notice a man taking a more than usual intelligent interest in his work he should be carefully watched, and assisted and raised in position as much as possible. Such a man, if trained from absolutely raw material, will make a good foreman and be a blessing; for good foremen are rare, and bad ones, legion. Probably the very best way to work the foreman question is to import a stranger as foreman—*i.e.*, a man who does not know the men whom he has to superintend. This method does away with a lot of trouble arising from favouritism.

As to the hours of work, the best hours undoubtedly are from 7 a.m. to 5 p.m., except on Saturdays, when knocking off time should be 1 p.m. If the men start at 7 a.m. they have their breakfasts before they come, and so get five hours' good work in before knocking off for dinner, for which they take one hour. If work is started at 6 a.m., as is sometimes the case, the men take from this time till breakfast time preparing their breakfasts Breakfast time being supposed to finish at 8.30, at least 2½ hours are completely wasted. Another point about the start at 6 a.m. is that foremen do not turn up punctually, unless the engineer makes it a rule to be there too. Overtime should be paid for at the rate of time and a quarter for the first two hours after the normal time, and then time and a half up till the next starting time. Double time should be paid from midnight on Saturday for any time worked between then and midnight on Sunday. As a general rule, however, overtime should be discouraged, as the same amount of work is never done in the same amount of time.

On the whole, it may be taken as certain that the best men, as far as best work goes, are to be found with electrical contractors, as these people will not have any men who are not well up to the mark, while on municipal undertakings many men are pushed into the work through the influence of residents, often to the chagrin of the engineer, who, although he is expected to make things pay, has to put up with these, very often most worthless men.

THE FACTORS WHICH DETERMINE THE DESIGN OF MONOPHASE AND POLYPHASE GENERATORS.*

BY B. A. BEHREND.

(Concluded from page 706.)

III. The Short-Circuit Characteristic.

In the preceding article the manner of determining the dynamic characteristic from the static and short-circuit characteristics has been set forth. If n is the number of conductors per pole and phase, I the current flowing through each conductor, and x the number of ampere-turns in the field for one closed magnetic circuit, then we have for a short-circuited armature the equation:

$$\lambda n I = x \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

In this equation λ is a coefficient varying with the dimensions of the armature and the field.

The theoretical determination of λ is extraordinarily difficult; indeed, it might be doubted whether any weight should be attached to such a calculation which must needs contain a great number of other coefficients, about the value of which we are equally as uncertain as we are about λ itself. It has been assumed as though it were a matter of fact that λ could easily be calculated from the ampere-turns of field and armature. If there were no primary and secondary leakage, this could, indeed, easily be done. The calculation yields a value for λ, according to the assumptions made, varying between 2·2 and 2·8 for three-phase currents. As there are a great many people who believe that λ, even if we neglected leakage, which is entirely unallowable, can be calculated by merely figuring out the maximum value (as some do) or the mean value (as others prefer) of the ampere-turns on the armature, it may be desirable to point out that λ depends very much, not only upon the arrangement of the armature winding, but also on the ratio of the width of the pole to the pitch of the poles. If the dimensions of the armature and field are properly taken into consideration, the lowest values of λ—that is, without leakage—can be calculated, and this is of some interest, as it will increase our surprise when, instead of $\lambda = 2\,7$, for instance, λ rises to 5·4—in other words, our generator gives us only one-half the short-circuit current that we expected it to give.

All of us who have been designing alternators for high frequencies or low speeds have had to go through such experiences. A great many speculations and wild guesses have been advanced to account for these apparent discrepancies between theory and observation. About three years ago I began to suspect that the absolute value of the pole-pitch might offer a clue to the explanation of these discrepancies. Almost all of the machines that I measured were of the inductor type, and in them the influence of the air-gap on λ greatly complicates the problem. But with the accumulation of experimental material, the problem grew more and more perspicuous, and the influence of the air-gap on λ could be separated from that of the pole-pitch.

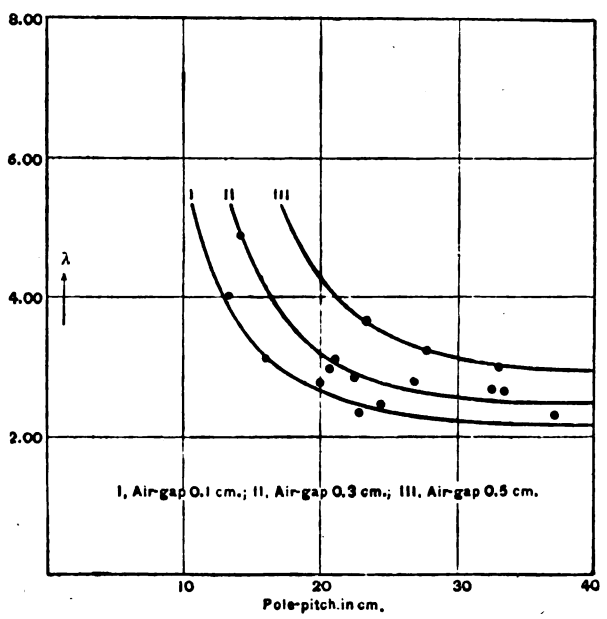

FIG. 7.—Values of λ

After the preceding it is hardly necessary to speak of the importance of λ as determining the design of the alternator. The output of single and polyphase generators working on power circuits, and, to a certain extent also, the output of generators working on light, is determined by the maximum drop permissible. This drop is directly proportional to the value of λ; hence I am justified in saying that λ is the factor on which hangs, in large measure, the success of the design.

The curves in Fig. 7 show the value of λ as a function of the pole-pitch and of the air-gap in three-phase inductor generators. The ordinates of the curves represent the values of λ, the abscissæ the pole-pitch. Curve I. is drawn for an air-gap $\Delta = 0\,1$cm.; Curve II. for $\Delta = 0\,3$cm.; Curve III. for $\Delta = 0\,5$cm. The magnetic and electric arrangement of the machines measured is shown by Fig. 8. The pitch of the armature coils was equal to the pole-pitch; the armature coils were lying in slots, one per pole and phase. The width of the pole-horns was equal to or slightly smaller than the pole-pitch. The most striking feature of these curves is their tendency to rise rapidly if the pole-pitch is smaller than 25cm. For small pole-pitches the air-gap is of intrinsic importance; with increasing pole-pitch the curves tend to converge. Let us

* From *Electrical World and Engineer* (New York).

Digitized by Google

try to account for these observations. If we diminish the pole-pitch, the magnetic flux emitted by each pole is diminished in the same ratio as the pole-pitch. If we assume that the magnetic resistance of the main field remains constant, then the ratio leakage field : main field, has increased in the same proportion as the pole-pitch has been diminished, since the magnetic resistance of the leakage field decreases in proportion to the pole-pitch. This holds good of the

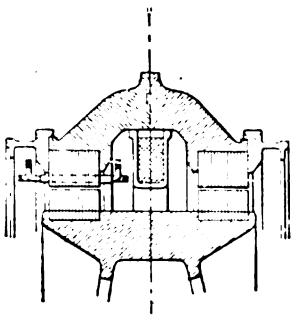

Fig. 8.—Details of Machine from which Values of λ were Derived.

leakage of the field as well as that of the armature, as can easily be seen. A glance at Fig. 9 shows that the leakage lines of the armature run in loops around the slots. The leakage remains, therefore, constant, whether we change the pitch of the coil or not. But the field which produces the E.M.F. in the coils varies in proportion to the pitch of the coil, hence the ratio, armature leakage : main field, varies inversely as the main field—that is, as the width of the pole, or as the pitch of the poles, since the ratio width of pole : pitch of pole may be assumed as constant. By means of the curves of Fig. 7, it is easy to find the value of λ for any pole-pitch and air-gap for three-phase current generators of the inductor type. My experience with generators with alternating poles is not sufficient to enable me to plot their λ curves for pole-pitches smaller than 20cm. For pole-pitches larger than 20cm. the values of λ agree well with Curves I. and II. For these large pole-pitches λ is practically independent of the air-gap; for small pole-pitches λ increases with increasing air-gap.

Frequency.—We are now in the position to study the bearing of the frequency on the dimensions of the generator. The question which the practical designer is called upon to answer is whether a generator wound for, say, 50 ⁓ can be more advantageously used for a higher or lower frequency. This question can immediately be answered with the help of our curves. A glance at them teaches us that the problem cannot be solved in a general way, but that each case has to be treated individually. As for the same voltage and the same magnetic frame the total number of conductors in the armature is the same for all frequencies—increased field leakage for small pole-pitches being neglected—the number of conductors per pole and

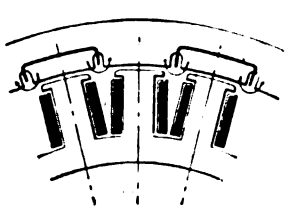

Fig. 9.—Illustrating Leakage.

phase is inversely proportional to the frequency, hence the short-circuit current for the same excitation, x, in the field can be given by the formula :

$$I' = I'' \times \frac{\lambda''}{\lambda} \times \frac{\sim'}{\sim''} \quad . \quad . \quad . \quad . \quad (3)$$

In this equation I' and I' denote the short-circuit current, λ' and λ'', the values of λ pertaining respectively to the frequencies ⁓' and ⁓''.

If a higher frequency is to be advantageous the quotient $\frac{\lambda''}{\lambda'}$ must be larger than the quotient $\frac{\sim'}{\sim''}$. An example will bring this into clearer light. The pole-pitch will be 25cm. for 50 ⁓. For 80 periods it would be 15·6cm. The value of λ for 25cm. pole-pitch is for an air-gap of 0·3cm. equal to 2·75, while it is for a pole-pitch of 15·6cm. equal to 4·15. Hence the short-circuit current for 80 ⁓ is equal to

$$I_{80} = I_{50} \times \frac{2{\cdot}75}{4{\cdot}15} \times \frac{80}{50} = 1{\cdot}06\ I_{50}.$$

In other words, the short-circuit current I_{80} is practically equal to the short-circuit current I_{50}. For the same drop the output of the 80 ⁓ machine is therefore equal to the output of the 50 ⁓ machine, with practically the same amount of iron and copper. Of course, it is obvious that the 80 ⁓ machine is more expensive than the 50 ⁓ machine, on account of the greater number of slots and poles, needing more insulating material and involving more labour. For 40 ⁓ we should have

$$I_{40} = I_{50} \times \frac{2{\cdot}75}{2{\cdot}57} \times \frac{40}{50} = 0{\cdot}86\ I_{50}.$$

Hence for 40 ⁓ the machine would give a smaller output than for 50 ⁓. For 60 periods we have

$$I_{60} = I_{50} \times \frac{2{\cdot}75}{3{\cdot}00} \times \frac{60}{50} = 1{\cdot}1\ I_{50}$$

In other words, the generator gives 10 per cent. more power for 60 ⁓ than for 50 ⁓. Table IV. contains the output of the generator for different frequencies.

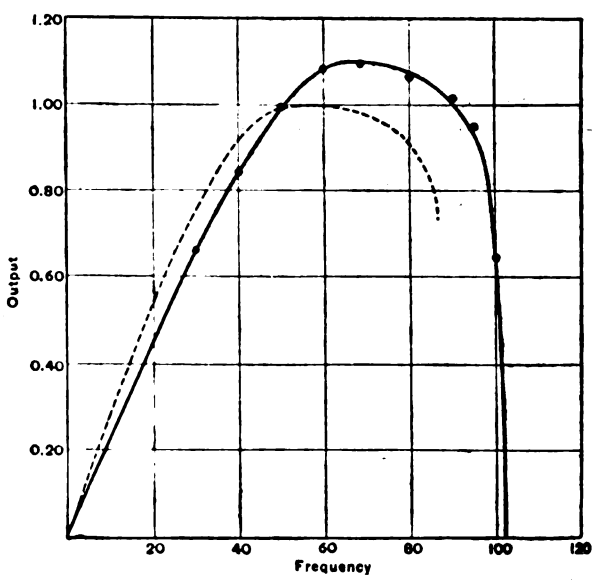

Fig. 10.—Frequency Curves.

Fig. 10 represents these relations graphically. The curve illustrates that between 45 ⁓ and 90 ⁓ the output of the generator is practically constant. If the increased field leakage at higher frequencies were taken into account, the curve would have the form of the broken line curve, and the output would, at no frequency, be greater than at 50 ⁓. If the frequency is increased above 80 ⁓, the machine is worked at a part of the curve where the slope is so steep that we can no more rely on any predetermination, as a very slight inaccuracy of the λ curve reduces the output tremendously. It would, therefore, not be advisable to work with a frequency higher than 80 ⁓. This, of course, holds good only in the case under consideration.

Table IV.

⁓	Pole-pitch.	λ	Output.
30	41·6	2·50	0·66
40	31·2	2·58	0·86
50	25	2·75	1·00
60	20·8	3·04	1·09
70	17·8	3·52	1·095
80	15·6	4·14	1·06
90	13·9	4·80	1·03
95	13·2	5·54	0·95
100	12·5	8·50	0·65

The way of reasoning here followed out supposes that the pole-pitch cannot be increased at higher frequencies. This is the case when the circumferential speed limits the diameter of the field. If circumferential speed does not

Digitized by Google

limit the diameter, as in slow-speed generators, mechanical and economical conditions restrict the diameter. The way chosen for the determination of the best frequency is therefore applicable in general.

In our calculation we have tacitly assumed that the induction in the air-gap is the same for all frequencies. This assumption involves a far greater loss through eddy currents and hysteresis with higher than with lower frequencies. For induction motors a low frequency of 40 or 50 is always desirable, as in them a large pole-pitch is of even greater importance than in alternators. How the curves of Fig. 7 can be used for the calculation of three-phase current generators will now be clear without further comment. The total sectional area of all the wires of the armature coils for which can be found room in the generator can approximately be set proportional to the circumference of the armature. Per 1cm. circumference of the armature we may reckon about ½ square centimetre of copper in the armature coils. Having thus found the amount of copper that we can place on the armature, the diameter of which being already determined, we find the number of convolutions of the armature coils by choosing a value for the current density, a good mean value being 300 amperes per square centimetre. Thus, the number of turns being found, we proceed to calculate by means of equation (1) the flux per pole. As the pole-pitch is known, λ can be taken from the curves of Fig. 7, the short-circuit characteristic can be drawn, and the dynamic characteristic be determined. It is not very long ago that the coupling in parallel of alternators was constantly under discussion I fully agree with Mr. W. M. Mordey that "there is no evidence whatever that lowering the frequency is an advantage in connection with parallel working, except in some inferior types of machines." Those who failed in coupling alternators for high frequencies in parallel, failed not on account of the frequency having been too high, but because the pole-pitch in their alternators was chosen too small, on account of the high frequency. They thus mistook a coincidence for a cause—a symptom for the evil.

Two-Phase Alternators.—Take a three-phase generator, separate the three phases, and connect two phases in series. The E.M.F.'s in the two phases, though unequal, are in quadrature with each other. The E.M.F. of the one phase being called E, the E.M.F. of the two phases connected in series is, then $E\sqrt{3}$. If we short-circuit these two phases, each in itself, the sum of the short-circuit currents is equal to the sum of the short-circuit currents in three phases when in star connection. The only difference between the two-phase machine in our case and an ordinary two-phase machine is that in the former one phase has one slot per pole, the other two; while in the latter the number of slots is equal in both phases. This will cause the short-circuit current to be slightly smaller in the latter case than in the former. From the foregoing we gather that λ for two-phase currents is equal to two-thirds of λ'' for three-phase currents.

$$\lambda'' = \frac{2}{3} \cdot \lambda''' \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Single-Phase Alternators.—The value of λ' for single-phase alternators is about one-half of λ'', sometimes a little more, sometimes a little less. This shows that for equal inductive drop an alternator wound for single-phase currents gives one-half more output if wound as a three-phase current generator. But as the load of single-phase alternators consists, in general, mainly of light, the power factor of the external circuit being as a rule near unity at full load, single-phase alternators may safely be wound for the same output as three-phase current generators.

The value of λ is, of course, influenced by the number of slots per pole. The following experiment will elucidate this point. Of two generators of the same type and size one was wound as a single-phase alternator, the other as a three-phase generator. The alternator had one slot per pole, the three-phase generator one slot per pole and phase, three slots per pole. The results were the following:

(1). Single-phase alternator, one slot per pole, $\lambda = 1{\cdot}56$.
(2). Single-phase alternator, two slots per pole, $\lambda = 1{\cdot}39$.
(3). Three-phase generator, three slots per pole, $\lambda = 2{\cdot}90$.

The output in these cases for equal inductive drop is as follows:

(1). $$\frac{E}{1{\cdot}56} = 0{\cdot}64\ E.$$

(2). $$\frac{\sqrt{3} \cdot E}{1{\cdot}39} = 0{\cdot}622\ E.$$

(3). $$\frac{3 \cdot E}{2{\cdot}90} = 1{\cdot}03\ E.$$

The figures speak for themselves, and need no further explanation.

We have seen that Dr. Behn-Eschenburg's method of determining the "synchronous reactance" in alternators gives results accurate enough for practical purposes; but we have also seen that the theoretical value of this method is a doubtful one. The investigator who attacks the problem of the determination of the inductive drop without foregone conclusions will, I feel convinced, arrive at similar results as those which are set forth in this article. The problem is not yet solved, but I doubt whether it will be possible to find a way of predetermining the "synchronous reactance" which is as simple and as accurate within certain limits as the way here taken.

To give experimental corroborations of Dr. Behn-Eschenburg's method of determining the "synchronous reactance"; to dispel the doubt that naturally hangs about a deductive method as long as experimental data do not underpin it; to point to the paramount influence of the leakage, as caused by a small pole-pitch, upon the inductive drop, and, therefore, upon the output of alternators—these are the main points to the clearing up of which I have endeavoured to contribute in this article.

TELEGRAPHS AND TELEPHONES AT THE PARIS EXHIBITION.

The following is an abstract of a paper read by Mr. J. Gavey, M.I.C.E., M.I.E.E., at the meeting of the Institution of Electrical Engineers last night. In the introductory portion of the paper Mr. Gavey pointed out that the various universal exhibitions that have been held in Paris since the year 1878, may not improperly be regarded as milestones along the road of progress in the telegraphic and telephonic industries. Such exhibitions afford unrivalled opportunities for the collective exhibition of new inventions in these industries, and by inspecting the State's telegraph exhibits one could tell how far the inventions of 1878 were employed in actual practice in the present day. The author then proceeded to treat his subject under three heads: telegraphs, telephones, and phonographs. Under the first heading there were three exhibits deserving of special mention, as they were designed either with the object of increasing the number of messages which can be carried by a telegraph circuit, or in order to avoid the labour of transcription at the receiving ends of circuits working with the Morse alphabet.

The first of these three new systems was that exhibited by the Rowlands Telegraph Company, of Baltimore. This consists of an apparatus for multiplex working, which will admit of eight messages being sent at the same time on one circuit—*i.e.*, four in either direction. Satisfactory results are said to have been obtained in America over 600 miles of actual line. Mr. Gavey explained that this was more than can be done with the present Delaney system at use in this country. This system depends for its accuracy on the synchronism between two commutators at either end of the line. If the retardation of the signals, due to the induction and capacity of the line, is then approximately as great as the commutating interval, confusion arises in the signals. Mr. Gavey explains that a modification of the Delaney system, designed by Mr. Pollak, of the General Post Office, is intended to obviate to some extent this defect. This was done by an improvement in the method of synchronising the commutators, which abolish hunting. The commutators were also divided into two concentric rings, the one for sending and the other for receiving. These can be shifted round relatively to each

Digitized by Google

other by an amount which could be made approximately equal to the retardation in the signalling. In the Rowland's apparatus the bad effects of retardation in the line were avoided by making the apparatus synchronous with the received signals and not with the sending period. In this system alternating currents were used to transmit the signals, and the commutator at the receiving end was made to run synchronously with the current received. This was done by a little alternator, which was driven by means of a

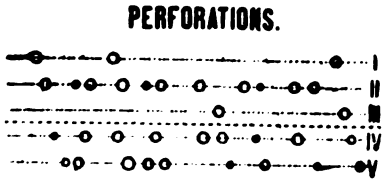

FIG. 1.

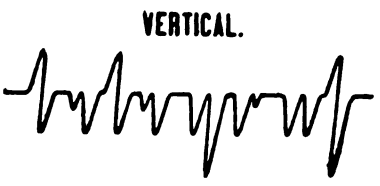

FIG. 2.

FIG. 3.

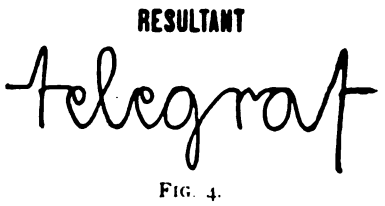

FIG. 4.

continuous-current motor until its speed of alternation was exactly the same as that of the received current. The signals are sent by 11 keys, two of which depressed at the same time correspond to a given typewritten letter. The signals are transmitted by hand, but are printed off automatically at the receiving end in such a form as to be ready for dispatch. Thus the exhibitors stated that each of the four operators at either end can send 30 words per minute, which corresponded to a speed of 240 words per minute over the same circuit. Arrangements were provided by which the sending operator moves the paper at the receiving end.

The next system described by Mr. Gavey was that of Mr. E. Mercardier, of Paris. By this multiple telegraph system it was claimed that 24 messages can be sent simultaneously over one circuit, 12 in each direction. This system was based on the harmonic system. A number of vibrating reeds were used, each differing from the rest by a certain defined period of vibration. These, when used to send signals to the line, caused a complicated system of vibrations to be set up in the currents transmitted. The line current was then analysed at the receiving end of the line by the series of receiving reeds or telephones only responding to the notes to which they had been tuned. With the Mercardier system Morse characters alone could be transmitted up to the present. It was stated that the inventor has been so successful with the tuning of the various parts that satisfactory results had been obtained on a circuit between Paris and Bordeaux. A complete metallic surface was, however, required for satisfactory working.

The third system of telegraphy referred to by the author was that of Messrs. Virag and Pollak. This system of photo-telegraphic and telephonic apparatus has been frequently described before. In the earlier forms Morse signals were transmitted at a high rate of speed, and these had to be transcribed at the receiving end. In the month of August, however, a paper was read before the Electrical Congress, describing an ingenious modification of the system by which telegrams are received in ordinary written characters: "In this modified system a metallic loop is employed, but it is joined up so as to form two circuits (Fig. 5), one being the ordinary metallic circuit, and the second a bridged and superimposed earth circuit of the type well known in telephony. To each of these separate electrical circuits is connected a telephone with a mounted mirror, which is vibrated by the movement of the diaphragm. These mirrors are so placed in relation to one another that a spot of light is reflected, first on one, then on the other, and lastly on the photographic record. The function of one of the mirrors is to receive impulses representing the vertical component of ordinary written Latin characters, whilst the second mirror receives the horizontal components. The transmitting is arranged by means of a punched slip with five series of perforations; the first three transmitting currents to the vertical component mirror, and the second two to the horizontal one. The line of perforations marked 1 (Fig. 1) transmits a negative current of a defined voltage; row 2, a positive current of the same voltage; and row 3, a positive current of double the voltage. Rows 4 and 5 transmit through the horizontal component telephone simple reversals. Two sizes of holes may be perforated along either of the rows, thus admitting of long or short contacts, and by means of a specially designed combination of perforations the vertical and horizontal components are so co-ordinated as to admit of the reproduction of written characters at the receiving end. In the diagram, Fig. 1 illustrates the perforations necessary for the transmission of the word 'Telegraph'; Fig. 2 shows the vertical components; Fig. 3 the horizontal; and Fig. 4 the resultant."

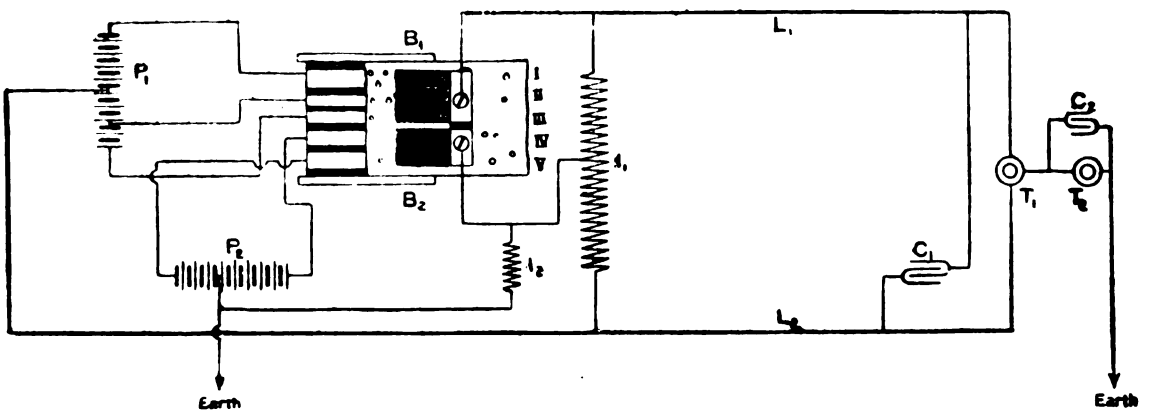

FIG. 5.

Since the last great exhibition in Paris the advance in telephonic practice has been, in Mr. Gavey's opinion, greater than that in the telegraphic departments. The most important advance mentioned in connection with the telephones has been the invention and perfection of the manufacture of dry-core paper-insulated cables. The use of metallic returns for overhead wires involved great expense, but this difficulty can be got over by using one of these cables, by which the wires to 200 subscribers can be drawn

Digitized by Google

into a 3in. pipe. Mr. Gavey predicted that in a few years the earth return for a telephone will be a thing of the past. The advantage of the complete metallic circuit included freedom from disturbance, the ability to use greater power microphones, and automatic signals. This automatic signalling, first insisted on by Sir W. H. Preece, has been greatly extended, as Mr. Gavey showed, in modern installations. Amongst the individual exhibits at the Paris Exhibition in the telephonic department, special mention is made of the central battery telephone switches exhibited by the Western Electric Company. As Mr. Gavey explained, this system of the central battery was being rapidly extended throughout the whole of the United States, and has been adopted by the British Post Office in London, by the National Telephone Company in some of its centres, and by the Belgian Administration in Brussels. He alluded to the advantages of this system in the economy of maintenance, the advantage of automatic signalling, the use of small incandescent lamps as indicators, and, above all, the uniformity in the character and volume of articulate speech. The other details particularly referred to were the Postel-Vinay switches, which consist of an automatic indicator placed immediately over the jack. The Siemens and Halske combined local subscribers' jack indicator. Besides these, several systems of party-line and multiple-way telephones were alluded to as worthy of notice.

As regards the manufacture of carbon granules for microphones, Mr. Gavey referred to the irregular granule which, so far, has been mostly used in this country, and to the regular small spheres of carbon about $\frac{1}{16}$in. in diameter. His conclusion is that there is little to choose between the two for microphone purposes.

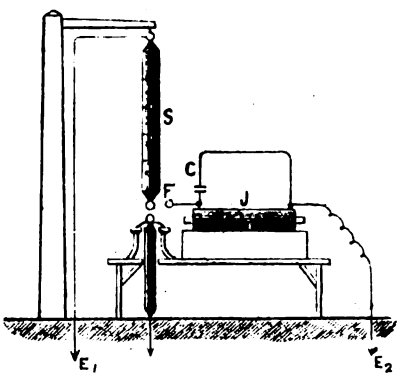

FIG. 6.

The wireless telegraph systems on exhibit were four, the first being that devised by Sir William Preece, which appears in the Post Office exhibit. The next system was the Hertzian system, as developed by Messrs. Ducretet and Popoff. Mr. Gavey stated that this was very similar to the Marconi system. The third system was that designed by Messrs. Slaby and D'Arco, and exhibited by the Allgemeine Elektricitäts-Gesellschaft. In this the inventors have replaced the usual vertical insulated wire, so well known in connection with wireless systems in this country, by a vertical cage, the upper end of which is connected to earth. This is illustrated in Fig. 6. At first sight it would appear as if the effect of the cage would to some extent be neutralised by the waves emanating from the return wire to earth, but probably the self-induction of the earth wire practically confines the oscillations to the cage. This, however, Mr. Gavey considers to be an interesting subject for speculation and investigation. The fourth exhibit was by the American Wireless Telegraph Company, who use a pneumatic arrangement for decohering. The author afterwards referred to the Poulsen microphonograph, which has already been described in our columns. Our readers will remember that the principle consists in recording by means of the transverse permanent magnetism in a continuous steel ribbon the vibrations caused in a diaphragm by the human voice. When the speech requires to be reproduced, this permanent magnetism sets up vibrations in a telephone diaphragm due to the current which it generates in the coils of a small magnet having its poles at either side of the wire. Mr. Gavey suggested that this invention may play an important part in the development of telephone repeaters as a means of increasing the range of telephonic speech, and also in decreasing the cost of long lines. Amongst the miscellaneous exhibits was one by the Telephone Hírmondo, which provides for the transmission of news in the city of Budapest. There were no less than 7,560 subscribers to this system on Jan. 1 last year. In practice, items of news are spoken into the main transmitting telephone every quarter of an hour, and these items are repeated until more interesting news takes their place—in fact, the system is an electrical substitute for an evening paper combined with a theatrephone installation. Mr. Gavey also refers to the novel state of the telephone systems in the city of Mexico. There anyone is allowed to start an exchange, the sole condition being that they must provide intercommunication with all other systems. The result is that eight separate companies are at work with an aggregate of 4,000 subscribers, the average rent for a telephone being half a sovereign per month. In conclusion, the author hopes that the paper may call the attention of the members of the Institution to a few of the most striking developments in the various departments of the Paris Exhibition treated on.

THE GLASGOW LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

A meeting of this section was held in the hall of the Institution of Engineers and Shipbuilders on the 14th inst. Lord Kelvin, G.C.V.O., president of the section, occupied the chair, supported by Prof. Magnus Maclean (vice-president) and Bailie Maclay (convener of the Glasgow Electricity Committee). A paper by Mr. W. A. Chamen, the city electrical engineer, on "Electricity Supply," was read and discussed. After a short speech from Lord Kelvin, in which he expressed his pleasure at presiding over such a crowded audience, he called upon Mr. Chamen to read his paper:

Electricity Supply.

BY W. A. CHAMEN, MEMBER.

This subject has been dealt with so often and by such able hands that the author feels some diffidence in venturing to write a paper upon it. The brief remarks which are now offered, however, will bear only upon two points in connection with the subject, and will naturally take some colour from the particular aspect of the question as applied to the city of Glasgow.

SYSTEM AND PRESSURE OF SUPPLY.

The fact that several undertakings which have commenced with an alternating single-phase high-tension supply have recently been actively engaged in changing their central or nearer areas to low-tension continuous current, supplied direct from dynamos fixed in the generating station without transformation of any kind, must surely be taken as a clear indication that low-tension continuous current is found to be more suitable and more economical for all purposes, where the distance is not so great as to make it too costly in copper. This change has, of course, been brought about by the alteration in the Board of Trade regulations allowing the use of a pressure in consumers' premises not exceeding 250 volts, and consequently of a three-wire system with a pressure not exceeding 500 volts across the outers. Mr. Addenbrooke, in a very able paper read before this Institution in London a few years ago, foretold this result, and showed that with a favourably selected position of generating station an area measuring five miles in diameter could be economically dealt with by means of low-tension continuous current under these altered conditions. Experience has proved this to be so, and in Glasgow the supply is at present carried on over a radius of 2½ miles each way from the new station at Port Dundas. It does not follow, of course, that it will always be economical to work in this way, as the load may grow to such an extent as to warrant putting down other generating stations at the more distant points rather than transmitting many thousands of horse-power through cables from a generating station already fully taxed by a demand of some 20,000 h.p. to 30,000 h.p. within a radius of much less than 2½ miles around it. On the other hand, there may be cases where small amounts of current require to be transmitted to exceptional distances, and in such cases small auxiliary high-tension plants, either continuous or alternating, would seem quite justifiable. The fact, however, that these may be neces-

Digitized by Google

sary is no reason whatever why the whole generating plant should be made high-tension and current transformed down even in central areas close around the generating station.

The obvious common-sense principle on which to proceed is surely to use simple low-tension direct supply at as high a pressure as possible, and when this fails to meet the case, to supplement with high-tension transmission for the remainder. A well-known consulting engineer, in a discussion on this subject some three or four years ago, went so far as to admit that this was the right line to go upon, but said that he found the public wanted an alternating-current supply and not a continuous one, and in consequence recommended that low-tension alternators be used for direct supply to the home areas and that step-up transformers be used in connection with this same supply for reaching the outlying districts, thus avoiding the necessity for any kind of separate generating plant for this purpose. The idea was ingenious, but the author is not aware that any use has been made of it, possibly because it has been found that the public do not, after all, want alternating current. For supplying motors or arc lighting who would prefer single-phase alternating current to continuous? And for incandescent lighting, what is to be gained by using alternating current? It may seem to be wasting your time to ask these questions or to put these arguments before you, but no less a genius than Mr. Ferranti only recently publicly stated his opinion that single-phase alternating current would yet come to be the universally accepted system of supply. There are, of course, those who say that two-phase or three-phase alternating current of low periodicity will shortly supersede everything else, but in their case the public are not found to want alternating current but continuous, and this is managed by means of rotary converters. The object of this system is said to be to allow the generating station (which for some reason, never yet satisfactorily explained, is bound to contain the whole generating plant of any one undertaking or more if possible) to be situated at a considerable distance from the area of supply, where land is cheap and coal readily obtainable. In a place like London, where the cost of land within the lighting area is practically prohibitive, where railway accommodation is impossible, and the conditions and restrictions arising through the interests of surrounding proprietors most onerous, there is no doubt some reason for adopting such a system; but it is somewhat remarkable that in the case of the Glasgow tramway power supply, in which this system is being introduced, there was much anxiety to get a site, not as near the coal-pits as possible, but as near the centre of the city as might be. The site ultimately purchased is about the same distance radially from the centre of the city as the Port Dundas electricity supply works, and figures were given to show both the extra capital which would be involved in going further afield and the annual extra cost through loss in distribution. Again, it is argued that the weak spot in a continuous-current system is the commutator of the dynamo, but experience has proved that this is an absolutely erroneous idea. Nothing could be more satisfactory than the running of the brushes and commutators of most of the dynamos as now constructed, and, in fact, two and three phase alternating systems rely entirely upon commutators in the rotary converters.

The conclusions to which these considerations seem to point are: (1) that there is no more economical or satisfactory method of supply than low-tension continuous current generated upon a site or sites within the area of supply if possible, and supplemented by a small amount of high-tension plant, if necessary, in order to supply remote corners of the area which may be beyond the reach of low-tension supply; (2) that if it be impossible to find sites within the area at any reasonable price, and with railway accommodation, and freedom from onerous restrictions due to surrounding proprietors, then a high-tension generating station or stations without the area will be the next best arrangement, though the cost of supply will be increased to some extent. And it therefore follows that in order to ensure supply at the maximum economy in years to come, sites should be retained in suitable positions within or as close as possible to the area of supply, and with proper railway accommodation and freedom from hampering restrictions, even at some sacrifice in the interval until they are required.

As regards the exact pressure of supply to consumers, it is obvious that the higher the pressure the more economical will be the distribution, and it must also be clear that where lighting and tramways are supplied from the same generating station, it is an advantage to have the pressure for both purposes alike. The pressure allowed by the Board of Trade for tramway supply is 500 volts, and the dynamos are usually constructed to run from 500 to 550 volts for that purpose. These same dynamos will therefore be most suitable, if they are to be used alternatively on lighting mains, for supply on a 500-volt three-wire system, using 250-volt lamps in consumers' premises, with balancers or equalisers to compensate for out-of-balance middle-wire currents. They will allow up to 50 volts drop in feeders at times of heavy load. The Board of Trade regulations for lighting place the limit for low-tension supply at 250 volts, but although the city of Glasgow has some 1,500 consumers, with a maximum load of about 3,000 kw. already supplied at this pressure, and the municipalities of Govan and Greenock have also considerable numbers of consumers supplied at the same pressure with complete satisfaction, the Board of Trade are declining to sanction more than 240 volts declared pressure in the London district and elsewhere. The argument appears to be that the 250-volt limit is one beyond which the pressure must on no account go, and that consequently it cannot be a declared pressure with the margin of variation allowed in another part of their regulations. Whatever may be the actual construction to be put upon the words from a legal point of view, surely it is unreasonable and inconsistent to take this line. The Board of Trade is appointed to look after the interests of the public, but in what way do the public suffer through being supplied at 250 volts? The thing is done, and is an admitted success. It has been in operation in Glasgow for about 18 months, and no trouble of any kind has arisen in connection with it. There can, therefore, be no scientific or practical reason why it should not be allowed. The proposal to establish 240 volts means yet another voltage to worry manufacturers and contractors, and through them the public. If the Board of Trade had taken the line of establishing a standard voltage for the benefit of everybody concerned, there would have been some clear object in it, but the result of this decision will be to make at least five different standard voltages—viz., 200, 220, 230, 240, and 250 volts—in use in various places in the kingdom. On the other hand, to agree upon 250 volts as the maximum declared pressure in consumers' premises would have tended to settle all new work down to this standard, and would have avoided the addition of another voltage to the already too numerous standards in use.

At a time like the present, when standardisation is so much taked about, electrical engineers will do well to give this matter special attention, and if necessary approach the Board of Trade in a body with a view to getting 250 volts sanctioned. It is hard, however, to see what necessity there can really be for taking so much trouble about so small a matter, as all that is required is for the Board of Trade to agree to that reading of Clause 1 in the "Regulations for Securing the Safety of the Public," which shall allow 250 volts to be a declared pressure, subject to the variation of 4 per cent. from that pressure, as laid down in Clause 7 of the "Regulations for Ensuring a Proper and Sufficient Supply of Electrical Energy." Probably the real reason why electrical engineers have not taken any decisive action about this matter is that all the older undertakings are already committed to some other voltage, and will naturally not feel called upon to press for 250 volts when they themselves use 220 or 230, and would not find it worth while to exchange to 250. This, however, is short-sighted policy, and it seems to have resulted in the meantime in the standardisation, not of any of the existing voltages, but of another one—viz., 240 for all new work. In the case of Glasgow, the author of this paper was faced with the problem of converting an existing 200-volt three-wire system into one of a higher pressure, and the question immediately arose as to whether it would be right to be contented with a 400-volt system, using 200-volt lamps in consumers' premises, or to adopt any higher voltage. While making an alteration, it was clear that if any departure were made from the simple multiple of the existing state of things, additional complications would arise in consumers' premises. The next consideration was whether the advantage to be gained was worth the complication and the cost thereof, and it then became necessary, in order to ascertain what the advantage would be, to settle upon some definite pressure as a basis for calculation. Granting that 250 volts could be used, it meant the difference between a 400 and a 500 volt supply—*i.e.*, an increase of 25 per cent. on the voltage. The value of this increase need not be enlarged upon in a paper addressed to electrical engineers. The advantages to be gained in the way of the saving of copper in the mains and ease of regulation of voltage over considerable distances seemed so great as to make it well worth while to take the step. Glasgow always wishes to be in the front line, and it certainly would not have been so had it settled down contentedly to a 400-volt three-wire system at the point when it was starting to lay a distribution system, designed rapidly to extend over an area of some 28 square miles. There is no doubt whatever in the author's mind that this alteration to 250 volts was the right step to take, and if the Board of Trade do not think so now, there cannot be the slightest doubt but that they will come to that opinion shortly. It is, however, much to be regretted that in the meantime other new undertakings should be started in various places at 240 volts instead of 250. There can be no cause for alarm or for the statement that it is a stretching of the regulations which will never end, for it must be quite clear to anyone that 250 volts is the absolute limit of declared pressure at customers' terminals (apart altogether from motive power supplies, which are granted at 500 volts by the special permission of the Board of Trade), and no one could possibly go beyond this figure without deliberately defying the regulations. The author holds, of course, that the regulations as they now stand are perfectly

Digitized by Google

capable of being read so as to allow this 250 volts as a declared pressure, and he doubts very much whether any judge, after hearing arguments, would not decide that the real meaning of the rules is that 250 volts may be used. The words of the two clauses upon which the whole argument depends are as follows:

A.—Pressure of Supply to Consumers.—(1) "The pressure of a supply delivered to any consumer shall not exceed 250 volts at any pair of terminals except with the express approval of the Board of Trade."

B.—Variation of Pressure at Consumers' Terminals.—"The variation of pressure at any consumer's terminals shall not under any conditions of the supply which the consumer is entitled to receive, exceed 4 per cent. from the declared constant pressure."

For a time a great deal was made of the argument that 250-volt incandescent lamps could not be made satisfactorily. Before deciding upon the matter, therefore, the leading lamp manufacturers were consulted, and they all stated that there would be no difficulty, and that they would be very pleased to take orders for such lamps. For the most part they had been as good as their word, and although some makers had not been quite successful as yet, they will no doubt shortly be able to fall into line with their competitors. Lamps of even 5 c.p. and 6 c.p. have been in use in Glasgow for over 15 months past at 250 volts without failure. The efficiencies of the good lamps now in use are: 5 c.p. and 6 c.p., 5 watts per candle; 8 c.p., 4 watts; 16 c.p., 4 watts; 32 c.p., 3½ watts, and 50 c.p., 3¼ watts per candle. There seems to be but little in the old idea that thin filaments could not be made to last. The leading manufacturers seem to have so far conquered their original difficulties in this respect that even 250 volts does not seem to be the limit to which they can go. Indeed, it seems doubtful whether in attempting higher pressures the proximity of the terminals in the present design of lamp would not cause greater trouble than the thinness of the filaments. Up to 250 volts, however, no trouble has occurred in this respect. There is another possibility to be borne in mind in connection with this matter, and that is the introduction in the near future of the Nernst incandescent lamp. The construction of the filament in this lamp lends itself most readily to the use of 250 or even 500 volts. The possibilities which lie before us with the Nernst incandescent lamp, giving the necessary light with about half the amount of energy consumed in the present form of lamp, combined with the advantages of the 250-volt supply, are great. A word may not be out of place on the vexed question of interfering with existing arrangements in some consumers' premises, such as two ordinary open-type arc lamps in series on 100 volts, special small motors for dentists' use, low-voltage heaters and cauteries, and such-like complications.

One frequently meets the argument that the increase in pressure is all for the benefit of the Corporation, and not for the benefit of the consumer. This argument is, of course, used by those who think that they will suffer by the change; but they are a very small minority, and do not realise that the object of the change is the cheapening of the supply all round. It is absurd to talk about "the benefit of the Corporation." Who are the Corporation but the representatives of the people, and whose is the undertaking but the people's? The object of the Corporation is to give that form of supply which is most economical, and consequently most convenient, for the majority. Electric light has been in the past too much the exclusive light of the rich man, who can well afford to pay a high price and to indulge in every kind of low-voltage complication which suits his own special fancy or convenience; but to maintain low voltage to suit these consumers means to keep up the price and to prevent the great British public from using electric light at all. The benefit of the majority, while at the same time dealing justly with existing consumers in making the change, is what the Corporation aims at. There are no dividends to make, and all profits are used, after providing for the lasting financial soundness of the undertaking, in reducing the price. The Corporation might have been content to leave things as they were and let the price remain high, but this would have prevented the growth and spread of the undertaking, leaving the supply to those who could afford to pay for it, and whose special and exceptional circumstances it happened to suit. Most people want light, and they want it in 8-c.p., 16-c.p., or 32-c.p. lamps. These therefore demand the first and most careful consideration. The question is how to supply these at the lowest cost. Having settled that, the other consumers must be made to accommodate themselves to the altered condition of things, and it is surprising, after all, how very little difficulty is experienced in modifying existing appliances to suit the new conditions. Voltmeters are met with in several houses supplied at 100 volts. They are not readily altered to suit 250 volts, but why should they be allowed to interfere with progress? They are at best most unnecessary and objectionable things for consumers to have. It is a significant fact that it is only in 100-volt supplies, as a rule, that these voltmeters are found.

In concluding, attention should be drawn to the anomalous position in which the Board of Trade have put the owners of undertakings by allowing them to increase the pressure of supply to all consumers, but only with the consent of such consumers in the case of those supplied previously to the date of the revised regulations. In Glasgow common-sense has always so far prevailed, but in London it does not seem to have done so, and a mere handful of consumers have in some cases held out against the change for no apparent reason whatever, except the unpleasant peculiarities of certain kinds of human nature. A deputation representing some of the London supply companies waited upon the President of the Board of Trade about the matter. While admitting that it seemed unfair for a few consumers to have the power of practically upsetting the whole undertaking, the President is reported to have said that the companies should have done more to conciliate the consumers. One cannot help feeling that the companies in London are hardly dealt with. Every improvement they try to make seems to be obstructed by County Council, Board of Trade, or some other body. They are supposed to be doing everything purely for their own selfish gain, and never with the object of improving the conditions for the consumer. Would not the case be very different if the local authorities of London all held the electrical undertakings in their own hands? Would the President of the Board of Trade have made the same remarks if the local authorities had been making the representation before him? Yet the necessity for the change is the same with the companies as with the undertakings in the hands of local authorities It is to be hoped that the Board of Trade will give compulsory powers in this matter of change of voltage, subject to arrangement or compensation to be settled by an independent arbitrator. The local authorities of London may quite possibly be the right parties to own the electricity undertakings, and it is their own fault that they are not so. Glasgow has realised the importance of the matter and purchased the original undertaking from Messrs. Muir, Mavor, and Coulson, and more recently the Kelvinside Company's undertaking. The whole of this latter company's consumers have now, with one exception, been changed to the 250-volt supply, and great progress has been made with the change of the old central area. Govan, which is not at present part of Glasgow, has started its own supply at 250 volts, so that if ever it is annexed it will join up with Glasgow without further change. In this way the whole of Glasgow and the adjoining communities are in a fair way to get a universal supply at 250 volts, with the exception of Partick, which is said, under the decision of the Board of Trade, to be laying down a supply at 240 volts. This is not good, but Glasgow may nevertheless congratulate itself that it is not like London.

During the discussion which followed, Mr. W. B. SAYERS, after referring to the once keen struggle between alternating and direct current, expressed his almost entire agreement with what Mr. Chamen had said. Direct current would, he thought, always be preferred in cities, particularly where there was a motor load, the chief reason being that speed control was so very easy. Well-designed direct current should and could give a wide and economical speed variation. A variation as wide as 1 to 3 was possible with good motors; certainly the ratio of 2 to 3 should be easily attained. With alternate currents no such variation was possible. Synchronous motors were absolutely constant in their speed, and with induction motors the speed at full load was dependent on the periodicity of the supply circuit, which was generally constant, and could not be varied with convenience. He also thought that there was no reasonable objection to 250 volts as a declared pressure.

Mr. MONTAGUE T. PICKSTONE spoke of some experiments which he had made with a view to obtaining wide and economical speed regulation. The plan was to introduce a counter E.M.F. into the circuit by mean of a motor-generator. It was possible by this means to vary the speed from the maximum to zero, and start up slowly in the opposite direction, all the speeds being obtained with the greatest possible economy.

Mr. JOHN M. M. MUNRO, referring to the battle between alternate and direct currents, pointed out that when the battle was fought in the abstract, and the conditions were the product of the imagination, no difficulty was experienced in proving the superiority of one or other system; the victory lay generally with the most eloquent advocate. Now, when there were numerous examples of both systems of supply scattered over the country, some comparison could be made, and it was obvious that in many cases the

Digitized by Google

advantages of one or other system were most pronounced. Hence it was easy to see that each had its own sphere of usefulness. He agreed that the recognition of 250 volts as a declared pressure was desirable in the interests of all.

Lord KELVIN said that many years ago he had a correspondence with Mr. Addenbrooke, who said that at that time lampmakers were ready to meet any demand for high-voltage lamps, and that no time should be lost in making the change to higher pressure in central-station work. He also remembered Swan's first lamps at 45 volts and Edison's at 100 volts, since which time the progress towards higher voltages had been gradual, but nevertheless sure. Some 18 years ago he suggested 300 volts as the safe limit at which current should be supplied to houses, and it was extremely satisfactory to see the gradual approach to that limit.

Mr. IONIDES spoke of the merits of polyphase motors, and of the possibility of varying their speed.

Mr. SAMUEL MAVOR, referring to the pioneer high-tension alternating-current system of Messrs. Muir, Mavor, and Coulson in Glasgow, said that prior to starting they had obtained the opinion of Lord Kelvin as to the most suitable system. His Lordship advised them to use a high-tension alternate-current system, in order to supply the scattered consumers. After a sufficient number of customers had been brought together, a low-tension direct-current system would prove the most economical. The purchase of the undertaking by the municipality prevented the firm following out the advice of their adviser, but the municipality had done so to its great advantage. On looking over the returns of some 100 supply stations, about 50 being alternate and 50 direct current, he noticed that there was only a small difference in the costs per unit—about ·3d —which showed that each system met the requirements of the town in which it was located.

Prof. MAGNUS MACLEAN made some observations on the number of stations which now supplied current at 200 volts or over.

Mr. W. A. CHAMEN, in reply, said that direct current had proved the most suitable system of supply to meet the requirements of a large variety of customers. Speaking of the suitability of wiring which had been done long ago to suit 100 volts, he said that on changing over no great trouble was experienced; generally all the work which had been connected to the mains within the last few years was suitable for the higher pressure. Switches on 100 volt circuits gave no trouble on 200 volts if the number of lamps were not increased—*i.e.*, switches which could safely carry five amperes at 100 volts could be used on 200-volt circuits if they were not required to carry more than 2½ amperes.

On the motion of Lord KELVIN, a hearty vote of thanks was awarded to Mr. Chamen for his paper.

THE PHILOSOPHY OF DYNAMO DESIGN.

(Specially contributed.)

(Continued from page 657.)

We have so far assumed that there is no internal resistance in either x or y, and that the only external resistances are those grouped at R′ and R″, but the student can readily demonstrate for himself that the results will be exactly the same if the resistances R′ and R″, in place of being collected together, are spread as internal and external resistances over the whole path. This is the case which obtains when we consider the process of commutation, while in addition, except when carbon brushes are employed, the path B C, which represents that which the brush makes by joining together two commutator sections, may be considered as to have only a perfectly negligible resistance. The process and reactions of commutation are exactly the same in both drum and Gramme wound armatures, but as it is simpler to show the various connections diagrammatically with a Gramme-wound armature, it is advisable to select this type for illustration. In all armatures wound with the ordinary two-circuit winding, the brushes are usually arranged to cover one and a-half sections of the commutator—*i e*, they first short-circuit one coil of the armature, and then two, and so on continuously. Fig. 20 diagrammatically represents a Gramme armature with the positive brush at the top, the current flows in a right-handed whorl up the right hand or a series of coils, and in a left-handed whorl up the left hand or b series of coils. Let us assume that the dynamos has to deliver 200 amperes to the outer circuit, then each series of coils must carry half, so that a coil of the a series prior to reaching the positive brush will carry a current of 100 amperes in a right-handed whorl. During the small period of time which it is under the brush this current must be delivered to the outer circuit, must cease in the individual coil, and as was previously stated, to comply with the conditions necessary for sparkless running a current of 100 amperes, neither more or less, must be generated in it in the opposite direction before it leaves the brush finally to pass into the b series of coils; and during this time the whole of the operations are further complicated by the self-induction of the coil, which tends, as we have seen, to prevent the stopping of a current already in existence, and also tends to prevent the formation of a new current. The average speed for a 200-ampere machine may be taken as 750 revolutions per minute, and there will probably be at least 50 sections, so that the actual time that the section is under the brush for all these operations to take place is $60 \div 750 \times 50 = 0{\cdot}0016$ second.

Fig. 20 shows the brush making contact with three sections, 1, 2, 3, and the two coils, d and f, are short-circuited, as the brush joins their otherwise open ends. A current is flowing in both the coils c and g towards the brush; that from g has three paths open to it—viz, $g\,y\,3$, $g\,f\,x\,2$, $g\,f\,d\,w\,1$—and that from c has also the same three paths, except that it would flow through the coils d and f in the opposite direction to that which the

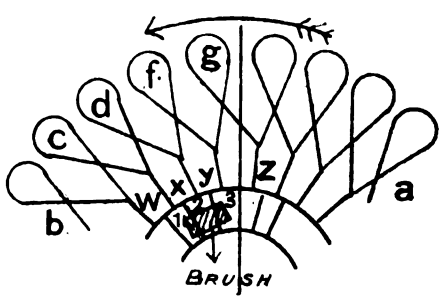

FIG. 20.

current due to the a series would; in addition, the coil d is just about to pass from under the brush and into the b series, and so, in order to fulfil the condition of sparkless commutation, it must be carrying a current in a left-handed whorl of 100 amperes. The vertical line in Fig. 20 represents the neutral plane, and it will be noted that the brush is shown with a forward lead, the short-circuited coils being all in advance of this neutral plane; if, however, we assume for a time that all the coils are not only in a neutral field, but that the armature is held stationary, and that a current of 200 amperes is made to flow through it from the bottom to the top brush, and, further, that the resistance of each coil without its lug is 0·001 ohm, and the resistance of each lug and commutator section is 0·001 ohm, then considering g and c to be the source of the E.M.F. forcing the current to flow to the brush, the resistances of the various paths would be $g\,y\,3 = 0{\cdot}001$ ohm, $g\,f\,x\,2 = 0{\cdot}002$ ohm, $g\,f\,d\,w\,1 = 0{\cdot}003$ ohm, so that were the b series of coils neglected 50 amperes would flow through lug y, 33·35 amperes through lug x, and 16·65 amperes through lug w, but as the resistance of the three paths for the current from the b series are also 0·001 ohm, 0·002 ohm, and 0·003 ohm, 50 amperes will flow through w due to this current, 33·35 through x, and 16·65 through y. Hence at the junction of the coils d and f there will be 16·65 amperes due to a series opposing, 16·65 due to b series, and the two currents will be assimilated and check each other's flow. This will result in only two paths being open for the flow of the a current—viz, $g\,y\,3$ and $g\,f\,x\,2$—and for the b series, $d\,w\,1$ and $d\,f\,x\,2$; so that the a current will divide between these two paths, 66·6 amperes flowing through lug y and 33·3 amperes through lug x, and the final adjustment of the currents through the lugs would be 66·6 amperes due to

Digitized by Google

b through w, 33·3 amperes due to b, and 33·3 amperes due to a—total, 66·6 amperes through x and 66·6 amperes due to a through y. Now, such an adjustment of the current has the benefit of being symmetrical, but would not be satisfactory in practice, for the condition for non-sparking is that at the moment when coil d passes from under the brush there shall be a current flowing in it equal to that flowing in the series to which is added—viz, 100 amperes—whereas we have seen that only 66·6 amperes are actually flowing; hence when it leaves the brush it will immediately have to be increased by an extra 33·3 amperes, and the self-induction will prevent this instantaneously being taken up by the coil, and hence when the armature has revolved into the position shown in Fig. 21 there will be a spark from section 1, which has just left the brush, to the brush due to this additional 33·3 amperes, and as the commutator will be positive to the brush, there will be a wearing away of the commutator. This result is similar to that which obtains when the brush has not a sufficient forward lead. By moving the brushes forward, as shown in Fig. 20, the coils d and f are brought out of a neutral field into the fringe due to the leading horn, and will be cutting lines of force in a direction which will tend to produce a current flowing in a left-handed whorl in these coils. Coil d being further advanced than coil f, a higher E.M.F. will be generated in this coil than in f, and as the resistances of the two coils are the same, it will follow that if each coil were short-circuited on itself, a heavier current would flow round d than round f.

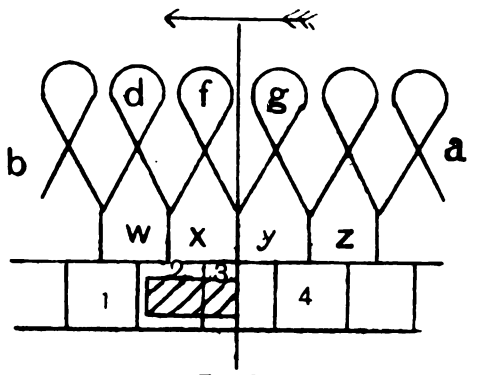

FIG. 21.

If the brushes be given too great a lead, very large short-circuited currents will be generated. We will suppose that, owing to excessive lead, a current of 200 amperes is generated in d and of 150 amperes in f. The condition of things is now greatly altered. There are the main a and b currents tending to flow as before described, while, in addition, there is the d short-circuited current of 200 amperes flowing in the same direction as the b current and having two paths—viz, $d\,x\,w$ and $d\,f\,y\,w$—and the f short-circuited current of 150 amperes tending to flow along $f\,y\,x$ and $f\,y\,w\,d$, the main current from g will be forced to all travel down the lug g, as the portion which before took the alternative path to the brush through coil f, lug x, and section 2 will now be met by the f short-circuited current and blocked. The currents in the three lugs will then be as follows: through lug y to the commutator will flow 250 amperes—viz, 100 amperes due to the main current from the a series plus 150 amperes due to the f short-circuited coil; through lug x will flow to the commutator 200 amperes due to the d short circuited coil, but this will be opposed by 150 amperes flowing from the commutator to the negative end of coil f, hence 150 amperes will be assimilated, leaving 50 amperes to flow to the commutator through this lug; through lug w will flow the 100 amperes due to the main current from the b series, but this will be opposed by the 200 amperes tending to flow to the negative end of coil d, and the main current will be assimilated, and 100 amperes only will flow from the commutator to the coil through this lug, so that we have a net result of lug y + 250, lug x + 50, lug w − 100, brush to external circuit − 200 = 0, which fully accounts for all the currents generated. In this case there will also be sparking, for when the segment 1 leaves the brush, as in Fig. 21, the current of 100 amperes flowing from the brush to the section will be broken, and as the brush is positive to the commutator, the brush will be worn away more than the commutator. If now the lead of the brushes be so adjusted that the E.M.F. induced in d is just 100, we shall get sparkless commutation whatever may be the short-circuited current in f, for this must be less with a well-designed armature than 100, say 75, then we should get 175 amperes through lug y to the commutator 100 − 75 = 25 through lug x, while through lug w there would be 100 amperes main b current to the commutator, which would be opposed by the 100 amperes tending to flow from the commutator to the negative end of coil d, and the currents would assimilate, and being equal in value there would be no flow at all through this lug; hence, when the position shown in Fig. 21 was being attained there would be no current in either direction to be broken, and consequently no sparking, whilst, moreover, the current in the coil newly added to the b series would undergo no violent change in volume upon passing from under the brush, and there could be no induction effects. It will be noted that the object to be attained in rightly fixing the proper angle of lead is not to feed the brush equally, but to divert the current from the nose to the heel; and if this be done, sparkless commutation will be obtained, but if the lead be too great or too little, sparking will ensue from the breaking of either the short-circuited or main currents.

If, as is very often the case, the theory of commutation were left here, the student might justly say, "You are continually talking generally about the self-induction of the coils tending to prevent the stopping of an existing current or the starting of a new one, yet in all diagrams you show currents flowing in the various short-circuited coils, and only mention the induction effect specifically in the one case of the current, in the d coil, being suddenly increased from 66·6 amperes to 100 amperes; how and when is the current reversed in the d and f coils?" The answer to this question is that the current must be stopped and reversed during the time it passes from g to d, and it is this time which has been previously given in a typical case as 0·0016 second. Considering for a moment our last illustration, where a short-circuited current of 100 amperes has been induced in d, we stated that in this case we should get sparkless commutation whatever may be the short-circuited current in f, and for an example 75 was taken, but if a value of 0 had been taken, the result would be the same. We should have had a flow through y of 100 amperes due to the main a coils; a current of 100 amperes through x due to the d short-circuited coil; and no current through w, with sparkless commutation. Hence at the instant when the coil d is thrown into the b series, there can be no current in f, and during the time it has already been under the brush the self-induction may have been gradually reducing the current flowing through it in a right-handed whorl, and during the period it has still to remain under the brush there is time for a short-circuited current of 100 amperes to be generated in it; for it must be thoroughly understood that it must not carry a short-circuited current of 100 amperes when in the position shown in Fig. 20, but this must be the value of the current just previous to the position shown in Fig. 21. If it were carrying 100 amperes at the instant depicted in Fig. 20, the current would be greater than 100 when the coil passed from under the influence of the brush, so that during the time the coil passes from g to f (Fig. 20) the self-induction may be opposing the stopping of the current flowing in a right-handed whorl, while during the period the coil passes from f to the time when it leaves the brush the self-induction will be retarding the growth of a current in a left-handed whorl. It will be readily seen that since $C = \frac{E}{R}$, and $E_{s\,s}$ will always be the same for any coil in postion d, f, or g, providing the dynamo output is constant, that the short-circuited currents will only be the same for all coils if the resistances of the various coils are equal. Hence it is most important in designing and building a dynamo to have perfect symmetry in the coils, not only in their positions on the core, but also in their length and resistance; dirty joints must be rigorously tabooed, for the resistance of any one coil is so very low that the increase or decrease in the resistance of

Digitized by Google

any one coil of the $\frac{1}{1000}$th part of an ohm will so far alter the induced current that we may get one coil when it leaves the brush carrying a current of 100 amperes, while the next coil may when it attains this position be carrying 200 amperes or 50 amperes. In either case intermittent sparking will ensue when the machine is run.

With smooth-core armatures some means have to be adopted in order to drive the inductors, a common device being to insert three or four driving horns. These may be made in two ways. A channel is milled across the core and an iron or wooden horn is driven in. This method has two objections: if iron is employed, the magnetic reluctance of the path from pole to pole is periodically decreased owing to the iron being brought nearer to the polar face; if a wooden or fibre driving horn be used, the magnetic reluctance is increased owing to the iron of the core being cut away at these points. In both cases there results unwarrantable fluctuations in the magnetic field. These driving horns, although a necessary evil, also destroy the symmetry of the armature coils, for whereas the majority of the coils lie evenly spaced round the armature (as in Fig. 20), at stated intervals a driving horn is inserted, and occupies the place of a coil, which is similar to leaving out coil *f*, or rather bending it back to occupy the position of coil *g*, so that when a horn comes between two coils which are under the action of the brush, they cannot both be in the proper position for sparkless commutation, and it is possible that intermittent sparking may ensue, especially as, owing to the horn itself, there is a

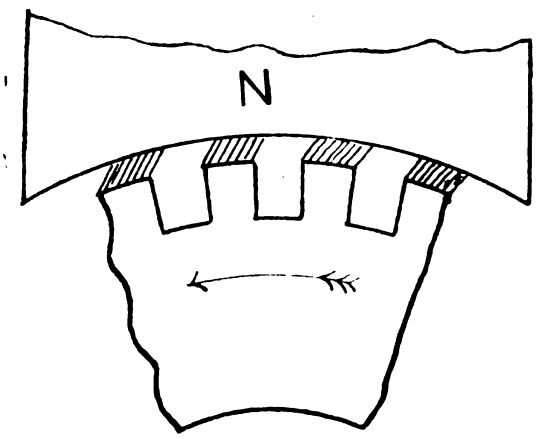

FIG. 22.

disturbance in the magnetic field. It will be readily appreciated that if, in place of inserting a driving horn, the full length of the core pegs are inserted in holes drilled in the core, the magnetic disturbance may be lessened, but is not obliterated. The cutting away of core for these horns is also to be deprecated on account of the burring together of the plates, which, as has been already seen, are carefully insulated from each other in order to prevent the formation of Foucault currents.

With slotted drum armatures the disturbing element of the driving horns is obviated, a more positive drive of each inductor is obtained, and solid copper inductors may be employed without fear of any heating from Foucault currents. Fig. 22 shows the arrangement of a slotted core; the lines of force, which are here represented as flowing from the pole to the core, are seen to be dragged in the direction of rotation of the armature. This dragging movement will be continued until finally the lines snap across the slot in which the inductors are laid. When speaking of the Foucault currents which would be generated in wide solid inductors on a smooth-core armature, it was shown that these currents were due to the difference of potential which obtained between the two sides of the inductor, owing to the number of lines of force cut per unit of time not being the same for the two sides. With inductors laid in a slotted core, and the lines snapping suddenly across the slot, it will be readily seen that the lines cut per element of time will be the same for the two sides, and that hence there will be nothing gained by the use of anti-Foucault stranded inductors, the cutting of the lines being performed as it were by a series of jerks. Other effects which will be produced by the employment of a slotted core are that, owing to the lines being dragged to their utmost extent and then snapping away, there will be a series of small closed magnetic rings formed on the polar face, and the magnetic field will be constantly and periodically disturbed; also the air space between the iron of the core (or rather teeth) and that of the pole-shoe will be greatly reduced, and consequently, not only will the reluctance of the path of the forward induction be considerably reduced, but also that in the paths of both the cross induction and back induction will also be reduced. While the reduced reluctance in the path of the forward induction may be said to compensate for the diminution of that in the path of the back induction, the diminution of the reluctance in the path of the cross induction is a very serious matter, as the effects of the cross induction will thereby be intensified. Various methods have been adopted to prevent any large amount of cross induction, some of which will be dealt with later.

(To be continued.)

THE CONVERSION OF THE METROPOLITAN DISTRICT RAILWAY.

According to one of the halfpenny daily papers, Sir William Preece has stated that there is to be an international battle of brains over five million sterling connected with the conversion of the Metropolitan District line to electric traction. We think a more correct statement of Sir W. Preece's views, after reading the article in question, will be that there is an international battle of brains for the most sensational news concerning this conversion. Another halfpenny daily, which is also noted for its advanced knowledge, claims to have discovered that the interview with Sir W. Preece emanated from an American yellow journal, in which it was printed on Nov. 9. The internal truth of the interview, in which it is claimed that Sir W. Preece has freely expressed his views, does not impress us. For instance, we can hardly conceive that Sir W. Preece would class the prominent English firm of Siemens Bros. amongst the German tenderers. It is well known that this firm constructed the experimental section of line between Earl's Court and High-street, Kensington, and that all the materials required and the technical skill also, were provided from English sources. The order in which the firms are mentioned would also lead us to suppose that an American reporter took a prominent part in the compilation of the article. It will have been remarked by our readers that the American firms are first mentioned in connection with the work, in spite of the fact that there are said to be more English firms sending in tenders. As a last evidence of the unreliability of the supposed interview, we would refer to the five million sterling which the conversion is said to cost. We should not be surprised to learn that the magnitude of this figure was intimately connected with the conversion of dollars into pounds. It will be seen from the advertisements inserted in the papers this week by the Metropolitan District Railway Company that they propose to introduce the Bill before the next session of Parliament to enable the company to convert their system to electric working. Powers are sought to this end, and to enforce on all of the companies having running powers over the system the use of electric locomotives. It will only be necessary in this case that the trains should be adapted for hauling by electric locomotives, as we presume that the locomotives themselves will be supplied by the Metropolitan authorities, as in any case these locomotives would draw their energy from the same generating station as the Metropolitan District trains. Under the proposed Act the capital of the company will be reorganised, and powers are sought to raise £500,000 in debentures, which would either rank in priority with the present debenture stock or on an equality with it. If this were granted, under the terms of their Act they would be able to borrow a further £166,000 in consequence. The company also seek powers to use for the conversion to electricity the whole or part of the £1,200,000 authorised

Digitized by Google

to be raised by the Metropolitan District Railway Act of 1897 and the additional £400,000 which could be borrowed in connection with the same under the same Act. It will be seen from these figures that the directors, if the Bill is passed, will have approximately 2¼ millions at their disposal. We do not think that all of this will be required. We believe that the last-mentioned sums were to be expended in improving the condition of the atmosphere in the tunnels by providing additional openings and forced circulation of air. If we are correct in our surmise, there is no reason whatever why the money should not be used for installing electric traction, which will give the same improvement in the condition of the air in the tunnels. The last rumour of the newsmongers is that the British Westinghouse Company are the real promoters of the above Bill, and that the same company will find the new capital as well.

SIMPLIFIED CALCULATION.

In a short contribution to the *Elektrotechnische Zeitschrift* Mr. Arthur Löwit points out that many trial calculations are necessary in the majority of cases in order to determine that diameter of wire which will give the requisite number of ampere-turns in a coil of given dimensions and with a given terminal potential. He then evolves a formula whereby the correct diameter may be at once found. From the calculated current density in the wire of the determined sectional area, it may then be decided whether the winding room at disposal is sufficient.

Let E = potential per coil;
i = current strength
R = resistance per coil;
n = number of turns;
L = total length of wire in the coil;
d = diameter of wire, in millimetres;
s = resistance of 1m. of wire of one square millimetre sectional area;
Z = number of ampere-turns per coil;
u = mean length of one turn.

Then
$$Z = n \cdot i \quad \ldots \quad (1)$$
$$n = \frac{L}{u}.$$
$$L = \frac{R \pi d^2}{4 s}.$$

By inserting the latter values in (1) we obtain:

$$Z = \frac{R \pi d^2}{4 \cdot s \cdot u} \cdot i = \frac{E \pi d^2}{4 s u}.$$

Whence
$$d = \sqrt{\frac{4 Z s u}{\pi E}} = 1{\cdot}13 \sqrt{\frac{Z \cdot s \cdot u}{E}} \quad \ldots \quad (2)$$

By introducing for the round coil $u = \pi D$ into formula (2), which serves equally well for any form of coil, we get:

$$d = 2 \sqrt{\frac{Z \cdot s \cdot D}{E}} \quad \ldots \quad (3)$$

For copper wire in a cold condition, $s = 0{\cdot}0166$, and for a round coil

$$d = 0{\cdot}258 \sqrt{\frac{Z \cdot D}{E}} \quad \ldots \quad (4)$$

It yet remains to decide whether the current density which would obtain for a wire of the determined diameter under the given conditions falls within the permissible limits. This may be calculated by means of a formula suggested by Uppenborn:

$$(d + \delta) = \sqrt{\frac{a \cdot \pi \cdot D \cdot l \cdot h \cdot s}{E}}$$

wherein δ = double thickness of cotton insulation;
a = density per one square millimetre;
l = length of the winding space in millimetres;
h = depth of the winding space in millimetres.

According to the formula, for copper wire and round coils

$$a = 19{\cdot}2 \frac{(d + \delta)^2 E}{D \cdot l \cdot h} \quad \ldots \quad (5)$$

Should the current density be found too great, the winding space must be increased accordingly.

As is apparent from formula (4), the number of ampere-turns remains unchanged so long as the mean circumference of a winding is the same.

THE GRAND.

A brand-new variety theatre to be called "The Grand," and meant to replace a popular music hall of the same name, is to be opened on the 26th inst. at Wandsworth, near Clapham Junction Station, under the managership of Mr. Arthur Yates, well known in a similar capacity at the Oxford, and at the Alhambra, Blackpool. The new building, which has an enormous seating capacity of the most comfortable description, is remarkable for having a very compact and well-arranged electric lighting plant of its own. The architect, Mr. Ernest H. I. Woodross, A.R.I.B.A., has provided three rooms on the ground floor, directly opening into the yard, for the reception of the machinery, which is just being placed *in situ* by Messrs. Geipel and Lange, of Victoria-street, Westminster. The centre room holds the dynamo, engine, and condenser; the others contain the boiler and the accumulators respectively. When one has got used to crawling about in dark and musty basements or other not easily accessible odd corners of theatres in search of the electric lighting plant, it comes as a pleasant surprise to see the engineers provided with plenty of fresh air and daylight. In the winter also the arrangement of having to work in a moderate-sized room will be found an advantage. The dynamo is a 120-ampere 160-volt continuous-current machine, made by Messrs. Laurence and Scott. It is directly coupled to a 20-h.p. high speed enclosed Reavell engine. Messrs. G. H. Hudson and Co., of Sheffield, furnished the economiser, and the boiler is of the Economic type, supplied by Messrs. Davey, Paxman, and Co., of Colchester. There will be 57 Tudor accumulators. The plant will provide for about 500 16 c.p. incandescent and 10 arc lamps, eight of which are at present erected. The wiring and lighting contract is in the hands of Messrs. Marryat and Place, of Hatton-garden, who also supplied the switchboard. Liquid resistances are used for dimming the incandescent lamps, which are on a 100-volt circuit. There are some very artistic brass chandeliers in the vestibule. We also noticed a plentiful supply of gas lamps all over the house. The whole work does much credit both to the architect and to Mr. C. Gray Hill, the contractor; and there appears to be every reason that the nightly rush for seats now taking place at the old hall will be transferred to the new building.

FORTHCOMING EVENTS.

MONDAY, NOV. 26.

Society of Arts.—At 8 p.m., Cantor lecture on "Electric Oscillations and Electric Waves" (lecture I.), by Prof. J. A. Fleming, F.R.S.

Institution of Electrical Engineers (Newcastle Section).—Ordinary meeting.

TUESDAY, NOV. 27.

Institution of Electrical Engineers (Manchester Section).—At 7.30 p.m., at Owens College, ordinary meeting. Paper on "Relative Advantages of Direct Current and Three-Phase Distribution for Small Installations," by Mr. H. A. Earle.

Institution of Civil Engineers.—At 8 p.m., ordinary meeting. Further discussion on paper on "The Metropolitan Terminus of the Great Central Railway," by Messrs. G. A. Hobson and E. Wragge; and, time permitting, paper on "Machinery for the Manufacture of Smokeless Powder," by Mr. Oscar Guttmann.

WEDNESDAY, NOV. 28.

Institution of Electrical Engineers.—At 7.30 p.m., students' meeting. Papers on "Single-Phase Generators at the Paris Exhibition," by Mr. J. T. Irwin," and "Polyphase Generators at the Paris Exhibition," by Mr. C. N. Nettley.

Institution of Civil Engineers.—At 2.30 p.m., students' visit to the L. and S. W. Railway Locomotive Works, Nine Elms.

THURSDAY, NOV. 29.

Institution of Electrical Engineers.—At 8 p.m., extra meeting at Institution of Mechanical Engineers. Paper on "The Supersession of the Steam by the Electric Locomotive," by Mr. W. E. Langdon.

FRIDAY, NOV. 30.

Institution of Junior Engineers.—At 8 p.m., at Westminster Palace Hotel, inaugural meeting of twentieth session. Presidential address by Sir Lowthian Bell, Bart., F.R.S.

SATURDAY, DEC. 1.

Institution of Electrical Engineers.—At 2 p.m. and 3 p.m., students' visits to the generating station of the Waterloo and City Railway.

Glasgow and West of Scotland Technical College Scientific Society.—At 7.30 p.m., ordinary meeting. Paper on "The Overstraining of Iron," by Mr. Jas. Muir.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

COMMON-SENSE PRINCIPLES.

As might have been expected, Mr. Chamen, in his exceedingly practical paper before the Glasgow section of the Institution, puts aside all fads and fancies and plumps for common-sense principles in electric central stations. Naturally, during the early years of any rapidly-growing industry there is a continued shifting of ballast; and the opinions of the "man in the street" vary with the shifting of the ballast. It is hardly to be expected that the majority of engineers will give allegiance to the view that "the obvious common-sense principle on which to proceed is surely to use simple low-tension direct supply at as high a pressure as possible, and when this fails to meet the case to supplement with high-tension transmission for the remainder." The battle of the pressures as regards electrical work is following the course of the battle of the gauges in railway work. By-and-by pressure will be more or less standardised, and so conduce towards the standardisation of machinery, which some manufacturers so much desire. Mr. Chamen brings us back to the consideration of direct as against all other methods of distribution. Within certain limits he concludes it is the very best, but that is just what many who had really thought out the question conceded from the commencement, and yet each fashionable craze has run its day. Recently the value of polyphase working has been urged. The fun is that no one doubts its value, but what a good many of us have often said is that no system is universally applicable; each must be considered on its merits, and the conditions surrounding each central station must be carefully examined before any system is adopted for the particular position. The most important question, however, raised by Mr. Chamen is not about direct or alternate current working, but is that of pressure and interference with previously declared pressure and the customers' installations. Here, as in other mundane matters, common-sense might with advantage be used. The world is a world of change, and if the change can be proved to be advantageous to both buyer and seller, the supineness or ignorance of the former ought not to be allowed to stop an improvement. It is needless for us to dilate upon the advantages to the generating station of a five hundred-volt pressure between the outers of a three-wire system as against a two hundred-volt pressure; they are well known. The more important question is how to reap those advantages. At the present time half a dozen, or even a single consumer stands master of the situation. The voltage has been declared at one hundred volts at the customers' terminals. The sellers desire to change over to five hundred volts between the outers, or two hundred and fifty at the customers' terminals, and practically all but these few of their customers agree. As the law stands, the change over cannot be made in face of this opposition. The seller may be perfectly willing to change the lamps, to make such alterations in the installations as are necessary at their own cost, to subsequently supply current at a lower cost per unit to the customer. Yet if the customer won't agree,

Digitized by Google

there is no help for it. Of course, we are assuming that the lower price of current will effectually compensate for decreased efficiency of lamps, if any, and that there is no doubt but that the consumer does get his share of the benefit through the change over. Mr. Chamen charges the Board of Trade with having caused some of the troubles to manufacturers, in that it has a varying policy as regards pressure. In Glasgow two hundred and fifty volts is the maximum, in London two hundred and forty volts—why? As Mr. Chamen says: "There can, therefore, be no scientific or practical reason why it (two hundred and fifty volts) should not be allowed" anywhere and everywhere. It may be doubted if the Board of Trade is the culprit in this instance, the varying pressures allowed being determined by the requests of the various engineers responsible for the supply at the different places. In Glasgow the engineer asked for and got permission to supply at two hundred and fifty volts at the terminals. In London the request was for two hundred and forty volts at the terminals, and other pressures at other places. The Board of Trade, however, is responsible for its own regulations, and the last part of paragraph 6 of Section B reads: "Provided that no change shall be made in the pressure of the supply to any premises which at the date of these regulations are supplied with energy by the undertakers, *except with the consent of the consumer.*" The italics are ours. All responsible authorities, whether connected with municipalities or companies, are in accord as to the necessity to alter this clause. Change for the better can be stopped by any consumer refusing consent, provided that customer was supplied at the date of these regulations. In this particular, then, the profession stands united, and we trust concerted action may be taken to bring the matter formally before the Board of Trade and to obtain a satisfactory remedy.

REVIEWS.

The Lead Storage Battery. By DESMOND G. FITZ GERALD. Biggs and Co., 139-140, Salisbury court, E.C. Price 7s. 6d.

This is a book which it is a pleasure to read, full of instruction and of experiment, steadily directed to a purpose, and as steadily reasoned out; but unlike many other books of which the same might be said, it is bright and readable, instead of requiring an effort to control one's attention. A good example of this is in Chapter VIII., illustrating the difference between exothermic and endothermic chemical reactions. One is rather puzzled when invited to consider the chemistry of 2½ cubic feet of carbonic anhydride, 36 grammes of water, 42 of nitrogen, 16 of oxygen, and 1 of hydrogen; nor does it greatly enlighten us to learn that it requires 397·3 foot-tons of work to reduce this somewhat heterogeneous mixture to the elementary condition. But this bears another aspect when we find that the substances represent some 5oz. of nitro-glycerine, capable of doing an enormous quantity of work while decomposing. This, of course, opens out the general principles of the storage of energy in chemical combinations.

The work commences with some seemingly elementary experiments upon coated lead plates; but simple as these may seem, they convey effectively that fundamental instruction which many are apt to think beneath them, but the clear comprehension of which is the only foundation of real knowledge, as distinguished from that which "everyone knows," but probably few really understand.

The early and seemingly obvious theory of storage or "polarisation" batteries was that their operation depended upon the decomposition of water, H_2O, into its nascent elements, and the so-called secondary actions of these upon surrounding substances, and especially upon "the combination of its oxygen with lead, to form PbO_2." Mr. Fitz-Gerald then shows that this is but a crude summing up of a final result of several intermediate processes, and that these several stages, reproduced in the course of discharge, correspond to the varying E.M.F. which is available.

It is shown by clear experiments that, contrary to a common opinion, PbO, lead protoxide, does not readily combine with acids; so, also, lead sulphate is with great difficulty formed into peroxide. These facts give an explanation of a loss in secondary batteries proportioned to the difference between 2·5 and 2 volts. Further study of the processes of "forming" in the Planté type, and of charging in the Faure or "pasted" type of cells, and of the various oxides of lead, shows that red lead, Pb_3O_4, is not, as often stated, a mere mixture of the proto and peroxide, but a definite stable chemical compound; it appears that the production of this, probably as a hydrate, corresponds to the high voltage stages, while the reduction of $Pb_2O_3 = PbO,PbO_2$, first to PbO, PbO, and then to 2Pb, or practically $2PbSO_4$ corresponds to the several lower stages. A corresponding compound, $PbO,PbSO_4$, is shown to be probably the harmless stage of sulphate of lead, readily oxidised in the charging. In justification of these theoretical studies in a work for practical men, it is most truly remarked, "I hold that the man who is practical, in the higher sense of the word, cannot work contentedly and satisfactorily to himself without having some clear conception of the causes involved in his results."

An interesting account is given of the various forms and processes of production of Mr. Fitz-Gerald's own peroxide, "lithanode." This substance, which has promise of a future, is the outcome of endeavours to combine porosity and solidity. This requires a cellular but continuous molecular structure, which can undergo chemical substitution of constituent radicals without destruction of the molecular cohesion and physical continuity.

A somewhat severe (but not unjustly so) criticism of Marchenay's chloride of lead patent specification introduces a full description of the many different forms of secondary cells which have been introduced. A discussion of the nature and properties of celluloid and pyroxylin will prove interesting and valuable to those who look forward to improvements, while those who have the present management of batteries will find abundant information in the many pages of formulæ and principles related to the due proportionment of active materials, acids, and vessels. The true economy, that is, the use of all necessary means towards the desired end, together with avoidance of everything unnecessary, depends on the understanding of such principles. There will also be found much information on the vexed problem of batteries for use with motors, which promises to be of so much importance in the near future.

The book is very free from errors of the press, but one on p 141, line 8, may confuse those not very familiar with chemical formulæ: $3Pb_2,PbO$ should be $3PbO_2,PbO$. A copious index, that essential element of a work of reference, completes a book which is likely to become a standard authority on the subject of storage batteries.

JOHN T. SPRAGUE.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

RATING OF INCANDESCENT LAMPS.

SIR,—Prof. Rowland's paper on this subject is, as Mr. Hobson remarks in your journal of Nov. 9, most interesting. Electrical engineers and lampmakers will no doubt give it the attention it deserves, and when they have fully digested it afford the general public the opportunity of profiting by

Digitized by Google

Prof. Rowland's observations. The paper, however, is of especial interest to me, owing to my close association with inventions having for their specific object to provide a remedy for the very defects which Prof. Rowland enlarges on. I trust, therefore, that for this reason, and in view of the fact that Mr. Hobson in his letter, while admitting the advantages of the spiral globe, refers to some alleged disadvantages attending its use, you will permit me space for the following remarks.

I gather from Mr. Hobson's letter he is of opinion that the ideal incandescent electric lamp would be one furnished

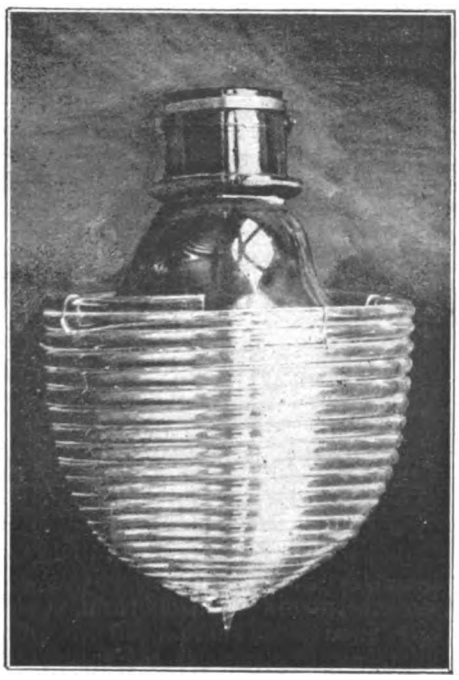

FIG. 1.—View of the Spiralette Globe.

with a device capable of refracting and diverting the side rays into the required direction without diminution. In this I cordially and emphatically agree, but I cannot admit that such a lamp is not at present in existence, for the spiral globe, which he refers to as being the "nearest approach to what is needed," more than fulfils Mr. Hobson's requirements. You will see that he himself bears witness to this fact, and anybody who takes the trouble to test the effect of the spiral globe with a photometer, as Mr. Hobson has done, must arrive at the same

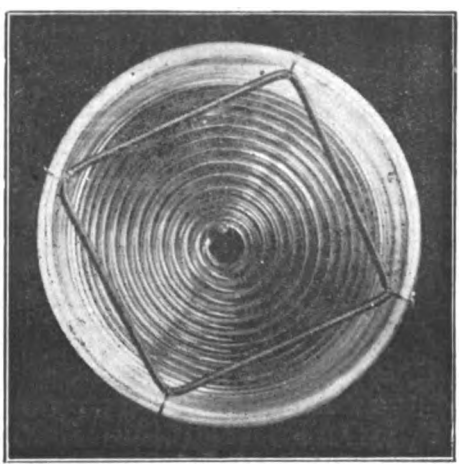

FIG. 2.—End View of the Spiralette, showing Springs for Gripping the Incandescent Lamp.

conclusion. This was, however, established two years ago, as will be seen by the test made by the Electrical Standardising, Testing, and Training Institution. I enclose copy of this test, by which you will see the increase given in effective illumination is from 70 to 100 per cent. in the most useful and desirable direction.

The objections to the spiral globe alluded to by Mr. Hobson are really of very minor importance when the advantages it possesses are taken into consideration. Moreover, one of them has to a considerable extent been very recently remedied. Hence I assume that Mr. Hobson, being a scientist, and not an electrical engineer, is not acquainted with these lamps as now placed on the market.

The objections are three in number—viz., weight, expense, and unsuitability for all kinds of installations. I am bound to admit the latter objection, for in the case of lamps surrounded by certain kinds of shades or other adjuncts the spiral globe is inadmissible. There are, however, such a vast number of lamps unprovided with shades, etc. (as in large premises, etc.), that this objection may be disregarded, for the spiral globe was primarly invented to secure comfort and not for ornamental purposes. Expense—*i.e.*, first cost of lamps—was not taken into account, for it was thought that the use of the invention would (and as a matter of fact does) result in such an increased illuminating effect, coupled with increased comfort, that the additional expense of the lamps would be warranted. Now, however, the lamp has been so modified that the possibility of putting the lamps on the market at a price very little in excess of the cost of ordinary lamps has been afforded. Hence one of Mr. Hobson's objections, at all events, falls to the ground.

However, this is only by the way, as my chief object in addressing you was to call Mr. Hobson's and your readers' attention to the fact that such a device as this gentleman asks for has been produced and is now being placed on the market. This device is a direct outcome of the spiral globe itself, and hence it is termed 'the electric incandescent mantle," the "spiralette." It is applicable to lamps of all makers, while being especially suitable for the "improved glow lamp" and Edison and Swan's "Queen lamp," in which a reflector projects the rays downwardly and renders the glare of the filament so intense so as to be hurtful to the eyes. This device consists of a hemispherical or cup-shaped screen constituted by a spirally-coiled glass rod (as in the spiral globe), provided with adjuncts which serve to secure the screen firmly in place on the lamp, these adjuncts being of such character that any person may apply and remove the screen instantly. In view of this, I am compelled to challenge Mr. Hobson's statement that there is not a cheap efficient device, applicable to every kind of lamp, serving to direct the rays into the required direction, and one which all lampmakers may use, for the "spiralette" possesses all these qualifications.

I might enlarge on the merits of the device, but I fear to encroach on your space. Consequently I will content myself with inviting all lampmakers and others interested in this very important subject to call here and see the device, of which I send you a specimen herewith for your inspection.—Yours, etc., S. B. APOSTOLOFF.

28, Bush-lane, E.C., Nov. 16.

[The two illustrations herewith we have prepared from the samples referred to. The cup-shaped spiral of glass rod is a wonderful example of what can be done in the fashioning of glass.—ED. *E. E.*]

THE DIRECTOR QUESTION.

We have received a copy of the following letter, which has been sent to the various shareholders of the British Electric Traction Company:

"Ladies and Gentlemen,—In view of the gratuitous distribution among the shareholders of the British Electric Traction Company of a paper containing an article, followed by several anonymous letters, commenting on the number of companies of which I am a director, I think it due to you to make this communication.

'The statements referred to are entirely misleading. All the companies of which I am a director are—with only one exception—associated companies of the British Electric Traction Company, in which that company has very large interests. I am a director of these companies in virtue of my position as managing director of your company, and by the instruction of your Board. Whatever fees or remuneration I receive from any of these companies are paid over to the British Electric Traction Company.

"The fact that it is necessary for the business of the British Electric Traction Company to be carried on mainly

Digitized by Google

by means of separate companies has already been fully stated to the shareholders in the annual reports. Those companies are in the nature of departments of your business, and it is the wish of your Board that I should for a time, at any rate, share both the responsibility and the satisfaction of establishing these companies on a successful basis.

"Prior to the formation of the British Electric Traction Company, I was a director of several electric lighting companies—*e.g.*, the County of London Electric Lighting Company and the Chelsea Electricity Company—but when, last year, my work as your managing director became heavy, I voluntarily resigned my directorships on all companies not directly associated with the British Electric Traction Company with only one exception.

"The exception is the Electric and General Investment Company, of which I have been a director since its formation 10 years ago, and I have retained my seat on that Board at the request of your chairman.—I have the honour to be, ladies and gentlemen, your obedient servant, "E. GARCKE."

THE RESISTANCE OFFERED BY IRON CONDUCTORS TO ALTERNATING CURRENTS.

The following is an abstract of an article contributed by Messrs. C. Feldmann and J. Herzog to the *Elektrotechnische Zeitschrift*:

If a conductor of somewhat considerable dimensions be traversed by alternating currents, the assumption of a uniform distribution of the current over the whole area of the conductor cannot be admitted. In fact, the individual lines of force generate local fields which are densest at the centre of the conductor, permitting only weak currents to pass there. Lord Rayleigh and, subsequently, Lord Kelvin were the first to draw attention to this fact. But it is well known that, so far as practical measurements are concerned, the increased resistance of copper wires arising from this un-uniform distribution of the current is a negligible quantity for the periodicities in vogue. If desired, the slight increase of resistance may, however, be approximately determined by means of the following formula:

$$R' = (1 + 7{\cdot}5 \cdot \sim^2 \cdot d^4 \cdot 10^{-7})\, R \quad . \quad (1)$$

or,

$$\frac{R'}{R} = 1 + \frac{1}{12}\left(\frac{2\pi \sim l\mu}{10^9 R}\right)^2 - \frac{1}{180}\left(\frac{2\pi \sim l\mu}{10^9 R}\right)^4 + \quad . \quad (2)$$

These formulæ are identical if we take the magnetic permeability, μ, in equation (2) as equal to unity. By substituting R in (2) by $\frac{\sigma l}{10^9 f}$, we obtain

$$\frac{R'}{R} = 1 + \frac{1}{12}\left(\frac{2\pi \sim \mu f}{\sigma}\right)^2 - \frac{1}{180}\left(\frac{2\pi \sim \mu f}{\sigma}\right)^4 + \quad . \quad (2A)$$

In equations (1) and (2) the diameter, d, and the length, l, are expressed in centimetres; the section, f, in square centimetres; and the specific electrical resistance, σ, in ohm-centimetres. Should the conductor, on the other hand, consist of magnetic material, μ in equation (2A) then becomes so great as to considerably complicate the calculation. Resource is therefore had to another formula, by which means, according to Messrs. J. J. Thomson and J. A. Ewing, approximate deductions may be made. Thomson has shown that in a plate of the thickness $2a$, which is magnetised by a current parallel to its length, a magnetic force, H_x, is set up vertical to this direction, having its maximum value, H_0, at the surface of the plate, while the amplitude of the force for any point within the area of the plate at the distance, x, from the plane through the centre of the plate (Fig. 1) possesses the following value:

$$H_x = H_0 \sqrt{\frac{\cos 2mx + \cos 2ma}{\cos 2ma + \cos 2ma}} \quad . \quad (3)$$

wherein $\cos 2mx = \cos$ hyp $2mx$

and

$$m = 2\pi \sqrt{\frac{\mu \sim}{\sigma}} \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Further, μ represents the magnetic permeability, and σ the specific electrical resistance of the plate. If, in order to picture the distribution of the lines of force in such a plate, we set down

$$\mu = 2{,}000,\ \sigma = 50,\ \sim = 10{,}000,$$

it follows that $m = 19{\cdot}85$, and we obtain for plates of different thickness the following table, Fig. 2 showing the distribution of the lines of force:

	$\frac{x}{a}=0$	0·2	0·4	0·6	0·8	0·9
$2a = 0\,05$, or $\delta = 0\,5$mm.	0·98	0·98	0·98	0·98	0·985	0·992
0 1 1· ,,	0·775	0·775	0·782	0·805	0·875	0·93
0·2 2· ,,	0·276	0·278	0·312	0 427	0·657	0 81
0·5 5· ,,	0·0	0·0	0·0	0·14	0 37	0·607

$= \frac{H_x}{H_0}$.

This magnetic shielding effect, which in the case of the thickest plate practically excludes all lines of force from the centre, may also be regarded as an imaginary jacket, which by uniform magnetisation with the full magnetic force, H_0, receives the same total magnetising current as the un-uniformly magnetised plate at the moment of the maximum. This equivalent thickness of plate on each side of the plate is

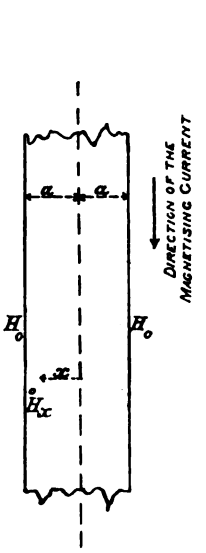

FIG. 1.

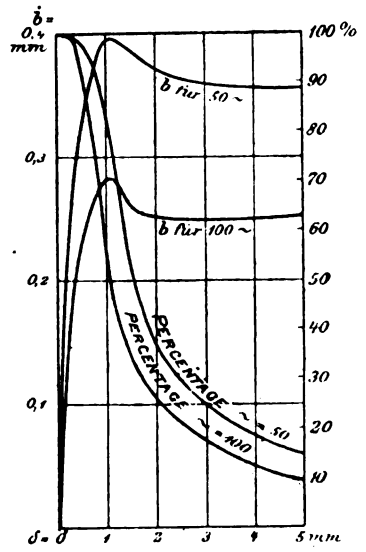

FIG. 3.

$$b = \frac{1}{m\sqrt{2}} \sqrt{\frac{\cos 2ma - \cos 2ma}{\cos 2ma + \cos 2ma}} \quad . \quad (5)$$

and amounts to the following values for the ratios given—that is to say, for

$$\frac{\delta}{m\sqrt{2}} = 0\,0355\text{cm}.$$

(Fig. 3), with

Millimetres.		Centimetres.	Percentage of the thickness of plate.
$\delta = 0\,5$	$b = 0{\cdot}0355 \times 0\,7 = 0{\cdot}0248$	.....	$= 99$
1	$= 0{\cdot}0355 \times 1{\cdot}12 = 0{\cdot}0398$	.....	$= 80$
2	$= 0{\cdot}0355 \times 1{\cdot}03 = 0{\cdot}0366$	.....	$= 36\,6$
5	$= 0{\cdot}0355 \times 1{\cdot}00 = 0{\cdot}0355$	.....	$= 14{\cdot}3$

For $m = 28\,1$ (corresponding to a periodicity of 100); the values of b, according to Ewing (Fig. 3), are:

Millimetres.		Millimetres.	Percentage of the thickness of plate.
$\delta = 0\,25$	$b = 0\,1245$	.....	$= 99{\cdot}5$
0·5	$= 0\,233$	.....	$= 93\,2$
0 75	$= 0{\cdot}285$	.....	$= 76$
1 0	$= 0{\cdot}282$	.....	$= 56\,4$
1·5	$= 0{\cdot}256$	.....	$= 34{\cdot}2$
2 0	$= 0\,250$	.....	$= 25$
∞	$= 0{\cdot}252$	.....	$= 0$

From the foregoing we may therefore conclude that the approximate penetration of the magnetisation into plates of moderate thickness amounts to only ½mm. with a periodicity of 50, while it is ¼mm. with a periodicity of 100. The same remarks apply with regard to the penetration of alternating currents into conductors of magnetic material. In the latter case the phenomena are identically the same, except that it is no longer the magnetisation, but the electrical current which decreases

Digitized by Google

so rapidly from the circumference towards the centre, that we may picture the electric current conveyed by the conductor at the moment of maximum flow as being substituted by an equivalent jacket round the conductor, which with a uniform density of current has the thickness

$$b = \frac{1}{m\sqrt{2}} = \frac{1}{2\pi}\sqrt{\frac{\sigma}{2\mu\sim}} \quad . \quad . \quad . \quad (6)$$

The assumption of an equivalent jacket seems to be, in general, only permissible for certain purposes; it corresponds in no way to the actual conditions, but enables a ready insight, and in the foregoing example also a quick computation to be made. In the same way as the magnetisation in a plate is represented in Fig. 2 we must likewise here assume the current density to decrease rapidly from the circumference of the iron conductor towards the centre at such a rate, for example, that the maximum current density at a depth of 1mm. below the surface represents only about 0·14, and at a depth of 5mm. less than $\frac{1}{10000}$th, of the density at the surface. Let the measured resistance offered by a certain conductor to the flow of an

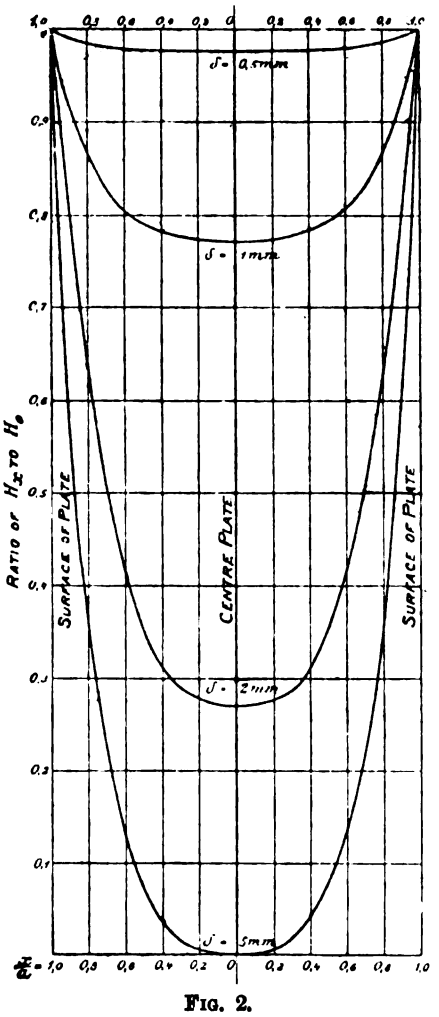

FIG. 2.

alternating current be R, to a direct current, R, the length of the conductor being l in centimetres and its section f in square centimetres. We may then, on the basis of the assumed equivalent jacket, calculated from the conditions

$$\sigma = \frac{10^9 . f . R}{l} \quad . \quad . \quad . \quad . \quad . \quad (7)$$

$$\frac{f}{f'} = \frac{R}{R'} \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

and from the known circumference of the conductor determine approximately the thickness, b, in centimetres, and from this the permeability, μ, for the magnetisation generated by the alternating current flowing through the conductor. For example,

$$\mu = \frac{\sigma}{(2\pi b)^2 . 2a} \quad . \quad . \quad . \quad . \quad . \quad (9)$$

or for $\sim$ = 50 periods

$$\mu = \frac{\sigma}{3{,}948 . b^2} \quad . \quad . \quad . \quad . \quad . \quad (9A)$$

Equation (7) indicates that on the basis of the assumed equivalent jacket we must consider only a part, f', of the total section, f, as conductive, the ratio of which part to the total cross-section is determined by the relation $\frac{R'}{R}$.

The values given in Table I. were ascertained in regard to some conductors of wrought iron, cast iron, and steel for a periodicity of 50. When the band No. 5 was spaced by means of wood blocks at a distance of about 3cm. parallel to the I-girder No. 4, a resistance R′ = 0 00833, which is somewhat greater than before, was obtained. An increased resistance due to the near proximity of a magnetic conductor is apparent here. In making such measurements especial care must be taken to obtain good contacts. These once secured, reliable measurements may then be made with the aid of a Weston milli-voltmeter and corresponding hot-wire ampere-meter, which should be calibrated before and after use, and may be used both for direct and alternating currents.

Certainly the degree of accuracy obtained in the tests given above will suffice to show that with conductors of wrought or drawn iron, and with a periodicity of 50 per second, the thickness of the equivalent jacket surrounding the conductor amounts to about ½mm., and that for the permeability in equation (5) we must set down 1,000 to 1,200. Table II. gives the complete figures relative to a test, from which we learn that with increasing magnetisation the resistance R′ (due to eddy currents) decreases somewhat.

TABLE II.—Outer diameter = 20·3mm.; inner diameter = 14·4mm.; $\sim$ = 50; tubes of 4,270mm. length.

Amperes.	135·5	124	143 5

This increase of the resistance is of practical importance in regard to railways worked by means of multiphase currents where the rails are used as a return. Under such conditions it is not advisable to take the figures which represent the resistance of the rail return for continuous-current working, since under the modified conditions a shallow depth only of the metal around the circumference of the rail profile must be regarded as conductive. Measurements made on the trial section of track belonging to the Helios Company, of Cologne-Ehrenfeld, gave the values set out in Table III. for a periodicity of 50.

The rails weigh about 44lb. per metre, the periphery of the profile being 472mm., and the sectional area 2,640 square millimetres. Properly speaking, the measurements Nos. 7, 8, and 13 only should be taken into consideration. These show that the rails without joints offered about nine times more resistance to the passage of alternating currents than to direct currents, while in the finished track the influence of the additional joints allowed the resistance offered to the alternating currents to attain only the four times the value as with direct currents. If it be desired to ascertain the influence of the joints in the 10m. length of metals, we must take into account the measurements Nos. 9 to 12; $\frac{R'}{R}$ for the joint and about 10cm. of the iron amounts to only about 2·2, but for 29m. of rails with three joints increases to 4 9, or for the same rail length and one joint less to 6·0. If we consider the rail joints in the same manner as the iron conductor, which seems justifiable only for the purpose of comparison, the influence of the joints on the fictitious values of b, σ, and μ is rendered still more apparent. For the purpose of the tests one only of the line of rails constituting the track was provided with joints, so that f = 26 4 square centimetres had to be set down also for the measurements Nos. 9 to 12. The measurements on the short lengths had to be conducted with currents of from 400 to 800 amperes, so that the pressure at the end terminals might be transformed up in order to render it readable on the milli-voltmeter.

The following further measurements relating to tests made with unlaid rails in the laboratory of Messrs. Ganz and Co., Budapest, have been placed at our disposal. In

these tests rails weighing 23·35 kg. per metre were placed side to side at distances of 30cm. apart, and over each other with 15cm. separation between each, this separation being regulated by means of alternate layers of wood in such manner that the equivalent of 68m. rail length could be subjected to the test. In order to lessen the mutual induction, the connections between the rails were made in zigzag fashion with stout copper wire.

The results obtained were as follows :

With Alternating Current $\sim$ = 15.
Sine Curve of the E.M.F.

Volts.	Amperes.	Watts.	Cos ϕ.
6·25	214	1,160	0·87
5·75	196	973	0·87
5·2	174·6	807	0·89

The resistance with direct currents was, therefore,

$$R = 0{\cdot}0082\ \Omega;$$

for peaked wave form of alternating currents,

$$R' = 0\ 043\ \Omega = 5{\cdot}25\ R \sim = 42;$$

for sine form alternating currents,

$$R'' = 0{\cdot}0295\ \Omega = 3\ 6\ R \sim = 15.$$

The effective loss was, on account of the hysteresis and eddy currents, in the first case four times and in the last instance three times as great as with the use of direct currents. The relatively high resistance observed in regard to the direct current may be attributed to the considerable magnitude of the contact resistance. For the same reason the increased resistance due to alternating currents appears relatively smaller here than for the conditions given in Table III. Taking into account the increased resistance due to the alternating currents, we obtain with a periodicity of 50 for

$$\text{1 km. length of rail about } R_s' = \frac{10}{W}$$

$$\text{1 km. track } R_{gl} = \frac{5}{W}.$$

Hence about eight times as much as for direct currents if W represents the weight of the rail per metre in kilogrammes.

For other periodicities, $\sim_1$, the numerators of the fractions vary in inverse proportion to the square roots of the periodicities. With direct currents carefully executed, rail joints double the resistance of the track. With alternating currents their influence is considerably less. If we assume 200 joints per kilometre of rail, each joint having a resistance of 0·0002 Ω, they will consequently present a combined resistance of 0 04 Ω. For a rail section giving a weight of 25 kg. per metre they will therefore represent about 10 per cent. of alternating-current resistance, whence for the finished track the alternating-current resistance,

$$R_g = \frac{5\ 5}{W},$$

or four to five times the amount which would be opposed to continuous current.

Hence, in using alternating currents, we may assume that the resistance no longer amounts, as for continuous currents, to from one-quarter to one-third that of the outgoing conductor, but to about one to one-and-a-half times that of this conductor, and that the effective loss in the rails may be determined from the fall of potential, the current, and the cos ϕ = 0·8.

Although these points should not be neglected, at the same time their importance must not be overestimated. The solution of the trunk-line problem will probably be reserved to multiphase currents in the one or other form, when the compensation pressure and effective loss may be rendered negligible by using slightly more copper in the lead, or by the partial use of copper in the return. Besides this, the existing tendency to adopt low periodicities—say from 15 to 20—for such railways will probably be pursued. A circumstance in favour of the latter practice is that multiphase motors for low periodicities and equal speeds require relatively fewer poles, and are therefore much more satisfactory. In virtue of this advantage, the increased initial cost of the primary plant and for transformers entailed by the low periodicities might be regarded in the majority of cases as balanced. However, in special cases it may appear advisable after careful consideration to adopt the most favourable periodicity.

The simple task of determining the resistance offered by the rails to the passage of alternating currents is, therefore, invested not only with theoretical interest, but also with considerable practical importance.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

Questions.

327. The commutators for large direct-current generators are frequently required by the engineer's specification to be assembled in such a manner that a portion of the bars may be removed without disturbing the remainder. How is this best accomplished, particularly with reference to the end insulating rings, which presumably would be in sections and would require skilful jointing?—Z.

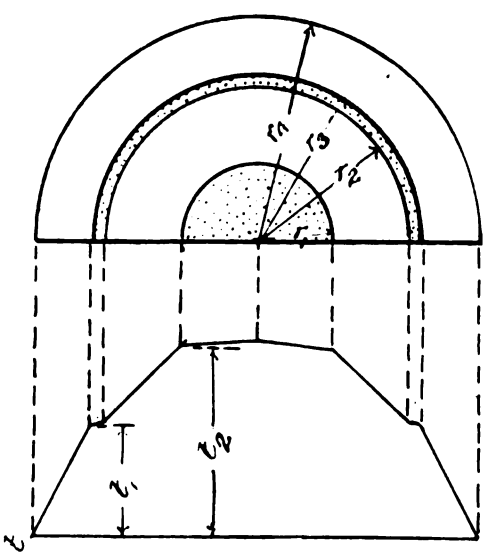
328. What should be a fair coal consumption for a 10-hour day with the following output—600 amperes 105 volts steady over the 10 hours. Engine is high-speed three-crank tandem compound single-acting, with variable expansion governor (rated as 127 b.h.p. with 100lb. steam pressure), coupled direct to 80-kw. dynamo. Steam is kept at 10lb. square inch higher than is registered by gauge (75lb. square inch) on engine side of governor valve, with 600 amperes. This is Lancashire boiler hot feed water.—Beta.

Answers.

Question No. 321.—Why does the temperature of the outer conductor of a concentric cable rise to nearly double the temperature of the inner when working at its full carrying capacity?

Best Answer to No. 321 (*awarded* 10*s.*).—A simple investigation proves that when any cable, concentric or otherwise, has acquired a steady temperature at all points of its section, the interior must of necessity be hotter than the outside, for heat always flows along the lines of temperature drop from regions at higher to those at lower temperatures, just as current flows from places at higher to those at lower E.M.F. Thus, if heat flows in any direction, the temperature drops in that direction.

Now, if the outer part of the cable were at any time hotter than the inside there would be a flow of heat radially inwards until the central region was as hot as the outside. For mathematical equality of temperature, it is true, an infinite time would be required, but it would be sensibly at the same temperature very soon.



The whole temperature condition at all points of a cable's section may be exactly determined by an application of the integral calculus, or found with sufficient accuracy by the following method, provided the following particulars are known: (*a*) The dimensions of the section. (*b*) The heat produced per centimetre length of each conductor = $C^2 R$ watts, where R is the resistance of each conductor in ohms per centimetre. (*c*) The conductivity of the insulation for heat = k. (The unit of heat is the calorie—*i.e.*, a quantity of heat sufficient to raise the temperature of 1 grm. of water 1deg. C. The heat conductivity of a substance is the number of calories which pass per second through each square centimetre of a plate of the substance 1cm. thick, and having 1deg. C. difference of temperature between its faces.) (*d*) The temperature, t, of the outside of the cable.

Now, assuming equal resistances for inner and outer conductors, $2\,C^2 R$ watts are liberated per centimetre length of cable per second. Since 4·2 watts = 1 calorie, this is $\frac{C^2 R}{2\,1}$ calories.

The flow of heat through any surface is given by calories per second = conductivity × area × temperature difference at faces ÷ thickness in direction of flow.

Hence t_1, the temperature inside the outer insulation, is found.

$$\frac{C^2 R}{2\,1} = \frac{k\pi(r_4 + r_3)}{r_4 - r_3}(t_1 - t)$$

$$t_1 = \frac{C^2 R (r_4 - r_3)}{k\pi(r_4 + r_3)} + t.$$

Copper being an excellent conductor of heat, no great error is introduced by considering the temperature of each conductor uniform across its section. The outer is thus at temperature t_1. Across the inner insulation, $\frac{C^2 R}{4\cdot2}$ calories pass per second. Hence, calling the temperature of the inner conductor t_2,

$$\frac{C^2 R}{4\,2} = \frac{k\pi(r_2 + r_1)}{r_2 - r_1}(t_2 - t_1)$$

$$t_2 = \frac{C^2 R (r_2 - r_1)}{k\pi(r_2 + r_1)} + t.$$

The temperature distribution is plotted in the sketch with temperature as ordinates on the diameter as base. Zero.

Answer to No. 321 (*awarded* 5*s.*).—It does not. The inner is always the hotter. For suppose the outer to be at the same or at a higher temperature than the inner, then it is obvious that no heat can pass from the inner to the outer; and if we take a considerable length of cable, there is no other way for the inner to lose heat. But heat is being continually generated in the inner and, therefore, its temperature must continue to rise until it fuses, however small the current. This is, of course, absurd. Therefore, it is clear that the inner must be hotter than the outer.—J. W.

Answer to No. 321 (*awarded* 5*s.*).—This question is one which turns upon the law of cooling of bodies. This law is stated in a simple manner by the following equation:

$$Q = E S \theta t \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

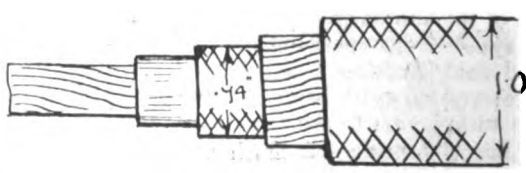
Q = quantity of heat to be dissipated;
S = area of the external surface of the body;
θ = the difference in temperature of the surface of the body and that of the surrounding medium;
t = time;
E = the coefficient of thermal emissivity for the particular radiating surface.

(Note.—Thermal emissivity is the quantity of heat per unit of time per unit of surface per degree of excess of temperature that the body loses to the surrounding medium.)

Transforming equation (1), we may write

$$\frac{Q}{t} \cdot \frac{1}{S} = E\theta,$$

from which it will be noted that $\frac{Q}{t}$ = rate of dissipation of heat. This, in our electrical question, will correspond to the watts lost in the cable. We may also note that $\frac{Q}{t} \cdot \frac{1}{S}$ = watts to be radiated for each unit of area of cooling surface.



We may now apply this law to our concentric cable. The accompanying shows a sketch of a sample of concentric cable which, when measured up, gave the diameter over the inner to be ·74in. and the diameter over the outer to be 1·06in. The cross-section of copper in the outer was equal to the cross-section of that of the inner. Consider a length of cable equal to L inches, then the resistance of the

Digitized by Google

inner for length L will be approximately equal to the resistance of the outer for the same length. Call the resistance R; let C = current flowing in the inner and also in the outer. Then

Watts lost in the inner = $C^2 R$.
Watts lost in the outer = $C^2 R$.

Therefore Watts to be radiated by inner = $C^2 R$,

and Watts to be radiated by outer = $2 C^2 R$.

Area of radiating surface of inner = $\pi \times 74$in. $\times$ L.
Area of radiating surface of outer = $\pi \times 1{\cdot}06$in. $\times$ L.

Also let E, the coefficient of emissivity, be the same for both inner and outer surfaces. Then equation for outer giving rise in temperature is:

$$\theta = \frac{2 C^2 R}{\pi . 1{\cdot}06 \times L \times E} \quad . \quad . \quad . \quad . \quad (2)$$

Equation for inner:

$$\theta_1 = \frac{C^2 R}{\pi \times {\cdot}71 \times L \times E} \quad . \quad . \quad . \quad . \quad (3)$$

Dividing (2) by (3) we get

$$\frac{\theta}{\theta_1} = \frac{2 C^2 R}{\pi \times 1{\cdot}06 \times L \times E} \times \frac{\pi \times {\cdot}74 \times L \times E}{C^2 R};$$

$$\therefore \frac{\theta}{\theta_1} = \frac{1{\cdot}48}{1\ 06} = \frac{1{\cdot}4}{1}.$$

Therefore, the ratio of

$$\frac{\text{rise in temperature of outer}}{\text{rise in temperature of inner}} = \frac{2 \times \text{diameter of inner}}{\text{diameter of outer}}.$$

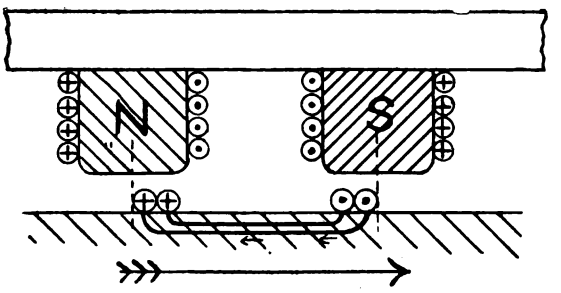
The above shows that the temperature of the outer of a concentric cable may be considerably higher than that of the inner, according to the relation between their linear dimensions.—P.

[N.B.—We give this reply as a sample of many we have received from men who, knowing their theory, will have been led astray by this question.—Ed. *E. E.*]

Question No. 322.—Being in charge of an alternating station having a motor-alternator, I have noticed that, when this is being driven off the big plant to charge cells, the excitation on the big plant is considerably less (about 15 per cent.) than when it is on lighting load alone, although the motor-alternator adds about seven primary amperes to the lighting load. If field resistances be altered to bring excitation on the big plant to a normal, machines merely drive badly. Required cause.

Best Answer to No. 322 *(awarded* 10*s.).*—I assume that the question is not meant to imply that the exciting current on the big plant is automatically reduced by putting the motor-alternator on load, but rather that a rise in the main voltage is occasioned thereby, in which event the man in charge of the voltmeter would naturally insert extra resistance in the exciter shunt circuit, thus lowering the exciter voltage, and, in consequence, the exciting current, and lowering the station voltage to the normal. If this is the case, it is almost certain, I think, that the alternate-current motor is over-excited—*i.e.*, the field is such that if run on a separate circuit at synchronous speed as a generator, the voltage at its terminals would be in excess of the main voltage of supply. If we were dealing with a continuous-current motor, and the field were thus increased, the motor would slow up, reducing its back E.M.F. sufficiently to allow the required current to flow, but in the case of the alternating-current motor the speed is fixed by the synchronous speed of the main plant, and the increased field produces a complicated reaction upon the armature current, which has the effect of causing it to lead in phase with respect to the E.M.F. of supply.

Now let us consider the effect of this upon the main machines. The figure depicts two adjacent poles of an alternator, and also an armature coil (consisting of two turns only for the sake of simplicity) in its middle position—*i.e.*, the position at which the rate of cutting magnetic lines, and consequently the E.M.F., is greatest. Now, if the current is absolutely in phase with the E.M.F., the current in this position of the coil will also be a maximum, and it is evident from the figure that the effect of this current will be to produce a magnetic pole midway between N and S, and of such a nature as to cause a resultant field in which the near side of N is strengthened and the near side of S correspondingly weakened. But the current in the coil is of an ever varying value, and it is plain, I think, that as the coil, when a little to the left of its present position, would be carrying a lesser current for an increasing value, its tendency would be to increase N; similarly, when past the middle position, the current will be decreasing, and its magnetic effect will correspondingly decrease S. So that when the current is in phase with the E.M.F., the armature field distorts that due to the magnets, but does not alter its total value, only inasmuch as it lowers the permeability of the poles by causing a crowding of magnetic lines at the near side of N.



Now suppose the armature current, instead of being in phase, has a *lead*, the current will now rise to a maximum before the E.M.F.—*i.e.*, before the coil reaches its middle position shown in figure; and in this case it is clear that N will be materially strengthened by the magnetic effect of the coil whereas when the coil passes into the position in which it would normally have weakened S, the current will have fallen to zero, or, at any rate, greatly below what it was when the coil held a corresponding position with reference to N. The net result of this lead, therefore, is to increase the strength of the field magnets. Similarly, if the current has a lag, the current in the coil will be strongest when nearest to S, and the net result will be a demagnetising effect. The maximum effect, of course, occurs when the lag or lead = 90deg., for then the armature pole, when the coil is carrying the greatest current, is directly under the field pole.

Now, the alternator armature possesses a certain amount of self-induction, and in all probability there is also a small self-induction in the main lighting circuit (particularly if asynchronous motors or series arc lamps are installed), so that the current will normally have at least a small lag, and will in consequence tend to produce the demagnetising effect upon the fields referred to above which effect must be compensated for by an increase in the exciting current. When the motor-alternator is running over-excited, the lead due to this will at any rate, partially neutralise the lag of the main current, and may, if the main current is not great, actually cause it to lead with respect to the E.M.F., and this would fully account for the difference in the excitation necessary for the main fields.

Now, the question also states that if the excitation on the big plant is brought to a normal, the machines merely drive badly. To raise the excitation to its original value would produce a corresponding rise in the voltage, unless the speed of the plant were reduced, and this, I presume, was done because such a rise would not be permissible on a lighting circuit. If this were the case, I expect it was this lowering of the speed that produced the unsteady running, for I have often noticed that with certain makes of alternators any deviation from the specified speed is productive of this effect.

Has the questioner tried the effect of lowering the exciting current of the motor fields? Because if the above explanation is correct, it should be possible to find a value for it which would cause no alteration in the excitation of the big plant. If the field reaction of the motor was causing the main current actually to lead, a reduction in its field would also produce a reduction in the current it was taking for a given load, whereas if the current as supplied to the motor has originally a lag, the reduction of the motor field may produce an increase in the motor current, because such reduction would decrease the leading effect which originally helped to neutralise

Digitized by Google

the lag, and thus a lagging current would be passing through the armature.—W. G. MURRIN.

Answer to No. 322 *(awarded* 5*s.).*—The cause of the change produced in the condition of the alternating generators when the motor is switched on is due to the lag in current of the generator owing to its load becoming more inductive, and also in part due to the increase of current. If, as is probably the case, the normal load be mainly incandescent lamps, and so non-inductive, the E.M.F. of the generator and its current are very nearly in phase together, the slight lag being due to the self-inductance of the armature. In this case the work done by the machine is the product of effective volts by effective

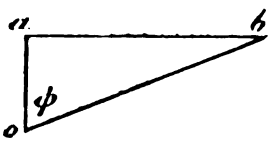


FIG. 1.

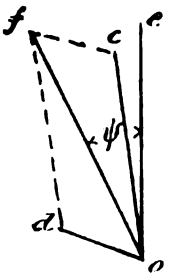

FIG 2.

amperes. When the motor is put on to the load the current, owing to its inductance, lags behind E.M.F. If $o\,a$ represent the product of effective amperes in the motor by its armature resistance, and $a\,b$ represent the counter E.M.F. of motor, then $o\,a$ and $a\,b$ being at right angles, $o\,b$ denotes in magnitude and position the supply pressure, and ϕ is the angle of lag—*i.e.*, the current reaches its maximum $\frac{\phi}{360}$ of a phase later than the E.M.F. in the motor (Fig. 1). The effect on the generator is found by setting off (Fig. 2) $o\,e$ to represent E.M.F., $o\,c$ to represent current in lamp load, and $o\,d$ representing motor current, the angle between $o\,e$ and $o\,d$ being ϕ. The generator current is now $o\,f$, the diagonal of $o\,e$ and $o\,d$, lagging by the angle ψ.

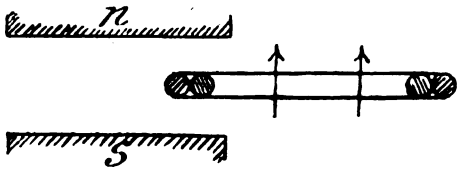

FIG. 3.

Now, where there is little or no lag, the reaction of the generator armature is a minimum, since the greatest current flows in the armature coils when they are in such a position as to have considerable magnetic resistance to their back lines (Fig. 3); when there is lag, however, the current maximum flows at a time when the coils have moved into a position having much less magnetic resistance, hence the field strength of the generator is weakened (Fig. 4). This weakening amounts in the machines mentioned in the question to as much as 15 per cent., giving a corresponding drop in the voltage of supply.

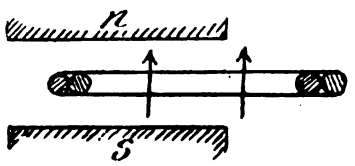

FIG. 4.

The back ampere-turns in the armature at a lag ϕ is in most alternators about equal to $\frac{N\,C\,2\sqrt{2}\,\phi}{\pi}$, where C is current and N the turns in one coil. If the excitation be increased by removing resistance from the magnet coils, the maximum E.M.F. is increased considerably, as is obvious from the fact that now the work done is the product of effective volts by effective amperes by cos ψ, and that this should be greater than before the motor was added. The conditions of working are thus considerably changed from those at which the engines and alternators usually run.—ZERO.

Answer to No. 322 (*awarded* 5*s.*).—To answer this question we must make two assumptions; each, however, is likely to be correct. The first is that the alternator is working on an inductive load, say supplying transformers, some of which are on light load. The result of this is that the current lags behind the E.M.F. When an alternator is supplying a current which is in phase with the E.M.F.—*i.e.*, when it is working on a non-inductive load—there is no lag and no armature reaction. When it is working on an inductive load of low resistance, the current lags almost 90deg. behind the E.M.F., and the whole of the ampere-turns on the armature oppose the field. At any intermediate point the armature reaction = ampere-turns on armature × sine angle of lag.

We will now consider the motor. It must be remembered that an alternating-current machine will run as a motor even when generating a greater E.M.F. than the source of supply, but in this case the motor takes a current which is in advance of the supplied E.M.F.—*i.e.*, it acts something like a condenser. Our second assumption, then, is that the motor is over-excited. It is possible that it is purposely over-excited, as it would be less likely to fall out of step; but it is not necessary to go so far as this. Suppose, as is probable, that the motor is brought up to synchronism, and up to the same voltage as the supply, and then switched in and loaded. There will be a fall of volts in the armature equal to CR_a, therefore the voltage driving current through the motor will be less than that generated by it, and we get a leading current.

The result of adding a leading and a lagging current depends on the comparative amperages of the two currents and the angles of lag and lead. To take an extreme case, consider the motor running light but over-excited, and the other circuit to consist of nothing but unloaded transformers, taking the same current as the motor. Then the two currents will almost neutralise one another and reduce the current in the generator to a very small amount, which will be in phase with the E.M.F. In the present case, however, the total current is increased by seven amperes, but the addition of the leading current of the motor to the lagging current of the other circuit has brought the current so much more nearly into phase with the E.M.F. as to reduce the armature reaction and the exciting current.—J. W.

PHYSICAL SOCIETY.

At an ordinary meeting of the Physical Society held on Friday last,

Dr. R. A. Lehfeldt read a paper on "**Electromotive Force and Osmotic Pressure.**" This paper is an attempt to explain a difficulty in the interpretation of the ordinary logarithmic formula for the E.M.F. between a metal and solution, pointed out by the author at the Dover meeting of the British Association. An expression for the E.M.F. of a concentration cell is obtained thermo dynamically upon the assumption that the electrolyte is only partially dissociated. A partition is used which is permeable to water but not to the salt or its ions, and the conclusion follows that the E.M.F. depends, not on the osmotic pressure of the metallic ions, but on that of the solution as a whole. A graphical representation is given, plotting osmotic pressure against dilution, assuming Boyle's law to hold, and it is shown that the E.M.F. is not proportional to the integral $\int P\,dV$, but is the converse integral $\int V\,dP$. Assuming, further, that the osmotic pressure changes according to Van der Waals's equation, the E.M.F. is greater than that calculated from Boyle's law. If the electrolytic solution pressure is calculated from the integral $\int P\,dV$, it comes out 10^{19} atmospheres, but if from the converse integral the value obtained is about 20,000 atmospheres. A comparison between actual E.M.F.'s and those derived from the equation given by the author should afford, if the formula is correctly deduced from the assumptions made, a measure of how far the osmotic pressure deviates from that indicated by Boyle's law. Experiments upon concentration cells have been made by Helmholtz, Wright and Thomson, Moser, Lussana and Goodwin, but as their work was performed upon cells with migration of ions, the calculation of the osmotic pressure is rendered uncertain by the introduction of the transference ratio. Accordingly, the author has measured the E.M.F.'s of cells without migration, using zinc as electrodes, and chloride and sulphate of zinc as salts. The E.M.F. was measured by the compensation method, using a Post Office box through which a current was sent by an accumu-

Digitized by Google

lator. The accumulator kept up a constant potential difference, and was standardised daily by means of a Clark cell. The experimental results agree with that calculated over the range centi- to dia-normal, showing that the deviation from the value given by the logarithmic formula is accounted for by the incomplete dissociation of the salts. The osmotic pressures are then calculated from the E.M.F.'s and the values of P V plotted. They show irregularities due to the combined effect of the decreasing dissociation of the salt and the increasing departure from Boyle's law. Dividing the product P V by Van't Hoff's factor, determined from conductivity, values are obtained showing variations similar to those observed in the behaviour of gases when subjected to high pressure.

Mr. Whetham said there was one form of membrane which is quite permeable to water, and yet does not allow either salts or the ions to get through. He referred to the free surface of the solution itself. The water being volatile can get out, but the salt cannot.

Dr. Donnan said the author seemed to have discovered things well known; for instance, the integral $\int V\,d\,P$ is generally taken as proportional to E.M.F. He expressed his interest in the explanation of the difficulty in the logarithmic formula.

Dr. Lehfeldt, in reply, said Goodwin had used the integral $\int V\,d\,P$, but had not made any nominal calculations by means of it.

Mr. A. Campbell then read the following papers: (*a*) "**On a Phase-Turning Apparatus for Use with Electrostatic Voltmeters.**" Electrostatic voltmeters are particularly insensitive at the lower parts of their ranges, the divisions closing in very much towards the zero point. When measurements of small direct-current potential differences have to be made, it is an easy matter to add to the voltage to be measured a constant voltage large enough to bring the deflection to an open part of the scale. If the small voltage to be measured is an alternating one, it is necessary that the auxiliary voltage should alternate with the same frequency and be in phase with it. The apparatus described enables the phase of the auxiliary voltage to be turned until it agrees with the one to be measured. The phase difference referred to is not the time lag, but the angle whose cosine is the power factor, and may be called the power lag. The method is to get two independent equal voltages, U_1 and U_2, differing in power phase by $\frac{\pi}{2}$, and to add together suitable fractions of these, such as $U_1 \sin \phi$, $U_2 \cos \phi$. The resultant is equal to U_1, but with the power phase joined through ϕ. The unknown small voltage is connected in series with an auxiliary voltage and a voltmeter, and the phase of the latter voltage is turned until the maximum deflection is obtained.

(*b*) "**On a Method of Measuring Power in Alternating-Current Circuits.**" The circuit in which the power is to be measured is connected in series across the supply circuit with a small non-inductive resistance. By means of a transformer the small voltage on this resistance may be transformed into one whose power phase is 180deg. behind the voltage on a non-inductive resistance. This is added to the voltage on the circuit to be measured, and then reversed and added again. The difference of the squares of these effective resultants is shown to be equal to a constant into the power to be measured. If there is any direct current, it must be measured separately by a Weston voltmeter or other suitable instrument.

(*c*) "**Note on Obtaining Alternating Currents and Voltages in the Same Phase for Fictitious Loads.**" When testing instruments for the measurement of large amounts of electrical power or energy, it is usually desirable to do so by means of fictitious loads—*i.e.*, by applying to the instrument under test current and potential difference representing the required load. In order to obtain a fictitious non-inductive load with alternating currents, the potential difference and current should be in the same phase. The current for the instrument under test is got by means of a transformer worked on a 100-volt circuit. The potential difference in the same phase is got by allowing the current to flow through a non-inductive resistance and increasing the voltage at the ends of the resistance to the required amount by means of another transformer.

The society then adjourned until Nov. 23.

LEGAL INTELLIGENCE.

WOLVERHAMPTON CORPORATION v. BRITISH ELECTRIC TRACTION COMPANY, LIMITED.

This important case was heard last week in the Chancery Division before Mr. Justice Joyce. The question at issue was connected with the sale by the British Electric Traction Company to the Wolverhampton Corporation of the tramways owned by them within the Corporation boundary. A draft contract for the sale was prepared, but the defendants refused to complete unless they were granted running powers over certain of the lines to be transferred to the Corporation. The value of the undertaking had to be ascertained by arbitration, and this had been done. From the evidence we gather that the dispute arose over a clause in the 1888 order known as the Dudley, Sedgley, and Wolverhampton Tramways Order, in which there occurs a clause which reads as follows: "If at any time hereafter any tramways are constructed or purchased within the borough of Wolverhampton by the Corporation of that borough, the promoters shall, if required by the said Corporation, and are duly authorised by provisional order or by Act of Parliament, make and maintain, at the joint expense of the promoters and of the Corporation, all necessary and convenient junctions between the tramways of the promoters and the tramways of the Corporation, and each shall grant running powers over their respective tramways."

It was argued by the counsel for the defence that without these running powers the inhabitants of the outlying districts supplied under the 1888 order would be seriously inconvenienced, and that the above clause gave them the right to running powers over the line to Wolverhampton, in spite of the transfer. It is worthy of note that certain of the urban district councils of the outlying districts supported the British Electric Traction Company in their defence.

After hearing the arguments on both sides, which centered around the interpretation of the above clause, **Mr. Justice Joyce** reserved judgment.

J. CAMERON v. P. C. MIDDLETON AND CO.

Sheriff Burnet at Aberdeen has issued an interlocutor in the action in which the trustees of the late Mr. John Cameron, contractor, sought to prevent Messrs. P. C. Middleton and Co., Limited, electric engineers, from so working their engines in the electric station at Cults, Aberdeen, as to cause annoyance to the neighbours. The defence was that the engines worked silently and smoothly, as well, indeed, as such engines possibly could, and that the noise made was too inconsiderable to cause any discomfort of which the law could take notice.

His Lordship found that the noise of the engines was such as to cause the plaintiffs material discomfort, and to diminish the use and enjoyment by them of their properties adjoining the electric station, and that the noise had diminished the value of the properties. His Lordship delayed granting an injunction, in order to give the defendants an opportunity of obviating all cause of complaint. He also granted leave to appeal.

MADRAS ELECTRIC TRAMWAYS COMPANY, LIMITED, v. COOPER AND OTHERS.

On Thursday, Nov. 15, Mr. Justice Cozens-Hardy, in the Chancery Division, delivered judgment in the case of the Madras Electric Tramways Company, Limited (Electric Construction Company, Limited), v. Cooper and others, the short point involved being whether the first mortgagees—debenture holders—who were in possession by their trustees, were entitled to the whole amount which had been advanced and expended by them on the Madras Electric Tramways Company's undertaking in priority to the second mortgagees.

After considering the claims, **Mr. Justice Cozens-Hardy** said he thought that he must find that the terms of the bargain were set out in the deed, and that he could not and ought not to consider what might have been the rights of the parties if the money had been advanced by the plaintiffs to the trustees independent of such a deed. In the result he must hold that any advances made by the plaintiff company subsequent to Nov. 25, 1898, when notice was given of the second mortgage, were postponed to the second mortgagees' claims.

MERCIER'S PATENT COMPANY v. NEW FLINT COLLIERY COMPANY.

In the Nisi Prius Court, Manchester, Mr. Justice Bucknill and a jury recently heard an action brought by Mercier's Patent Company, Limited, against the New Flint Colliery Company, Limited, for the recovery of money for goods supplied and work done.

According to counsel's opening statement the case arose out of a telephonic installation in a coal-pit belonging to the defendant company, which was carried out by the plaintiffs. Their charge for this and for the supply of certain accessories was £295, of which the defendants had paid £175 on account, the balance being refused on the ground that the installation was defective, and that the prices were excessive.

Mr. Mercier, managing director of the plaintiff company, described the arrangements between the parties and the manner in which the work was done, and said the telephone frequently failed to act, but this was due to the presence of an unusual amount of water in the pit, and to mishandling by the employés of the colliery company.

After hearing witnesses for both sides the jury returned a verdict for plaintiffs for £90, this being in excess of the £75 paid in court by defendant, who would also have to bear the costs.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ilford.—The Urban District Council invite tenders for the supply of lamp columns in quantities of about 50 at a time. Tenders by Nov. 26.

Kendal.—The Corporation invite tenders for the supply and erection of various plant. Tenders by Dec. 1. Details in our advertisement columns.

Digitized by Google

Aberdeen.—The Lighting, etc., Committee have resolved to invite offers for boilers, batteries, etc., for the electricity station.

Blackpool.—The Corporation invite tenders for the supply of arc lamp carbons and oils for one year. Tenders by Dec. 17. Details in our advertisement columns.

Brighton.—The Council invite tenders for the construction of the permanent way of the tramroads. Tenders by Dec. 13. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for supply of 12 workmen's tramcar bodies. Tenders by Dec. 1. Details in our advertisement columns.

Partick.—The Commissioners invite tenders for electricity meters, demand indicators, and fuses. Tenders by Dec. 4. Details in our advertisement columns.

Birkenhead.—The Corporation invite tenders for switchboard and instruments for Craven-street generating station. Tenders by Dec. 4. Details in our advertising columns.

Halifax.—The Tramways Committee invite tenders for tramcars, trucks, motors, and electrical equipment for same. Tenders by Nov. 27. Details in our advertisement columns.

Cuevas (Spain).—Applications are invited by the Municipality for electric lighting of the town for 20 years. Tenders by Nov. 30. Specification, etc., may be seen at the office of this paper.

Bermondsey.—The Vestry invite tenders for arc lamp columns, arc and incandescent lamps, automatic switches, and fittings. Tenders by Dec. 3. Details in our advertisement columns.

Hendon.—The Urban District Council invite tenders for the supply and erection of various plant for the municipal electricity works. Tenders by Dec. 31. Details in our advertisement columns.

Nottingham.—Tenders are invited for the installation of an electric lighting plant at the new workhouse. Specifications may be obtained from Mr. G. Muncaster Howard, clerk, Poor-Law Offices, Nottingham.

Portsmouth.—The Corporation invite tenders for the overhead electrical equipment of tramways in the borough of Portsmouth, and extending to Cosham, Hants. Tenders by Dec. 7. Details in our advertisement columns.

Wolverhampton.—The Tramways Committee invite tenders for electric motor tramcars. General conditions, etc., may be obtained from Mr. J. W. Bradley, borough engineer, Town Hall, Wolverhampton. Tenders by 26th inst.

Oldham.—The Electricity Committee invite tenders for the supply, delivery, and erection of an extension switchboard for supplying current for the tramways. Tenders by Nov. 27. Details in our advertisement columns.

Bexhill.—The Council invite tenders for the supply, delivery, and erection of a water-tube boiler and pipework and one 150-kw. steam dynamo at their electricity supply station. Tenders by Dec. 10. Details in our advertisement columns.

Cardiff.—The Corporation invite tenders for the following: (Section 4) 75-kw. motor-generator and Tudor storage battery; (5) lead-covered cables; (6) 20-ton travelling crane. Tenders by Nov. 28. Details in our advertisement columns.

West Ham.—The Council invite tenders for two 25-b.h.p. oil-engines, two 15 kw. dynamos, one battery of accumulators, switchboard, etc., at Dagenham Hospital, Essex. Tenders by Nov. 30. Details in our advertisement columns.

Southwark.—The Electric Light Committee invite tenders for the supply and erection of certain back E.M.F. cells at the Corporation electric light station, Penrose street, Walworth-road. Tenders by Dec. 3. Details in our advertisement columns.

Oldham.—The Tramways Committee invite tenders for the erection of a tramway car depot at Wallshaw, within the borough. Specifications, etc., may be obtained from Mr. S. A. Pickering, A.M.I.C.E., borough surveyor, Town Hall, Oldham. Tenders by Dec. 5.

Budapest (Hungary).—A telephone exchange to accommodate 10,000 subscribers is to be constructed at the Government expense. It is designed so that at some future date it can be made to include a further 10,000. Firms of any nationality may submit tenders for the work.

Dublin.—Tenders for the hire of plant, etc., required for the electric lighting of the State apartments, Dublin Castle, during the next Castle season, will be received at the Office of Public Works, Dublin, up to 10 a.m. on 27th inst. Specification can be seen at the Office of Public Works.

Brighton.—The Council invite tenders for the supply and delivery of the following: points, crossings, etc., soleplates, manhole covers with frames, gully grates with frames, tie-bars, fishbolts, and other bolts for fastenings, etc. Tenders by Dec. 6. Details in our advertisement columns.

Newcastle-upon-Tyne.—The Tyne Improvement Commissioners, Northumberland and Albert Edward Docks, invite tenders for the supplying and laying of cables, and the fixing of wires, poles, arc and incandescent lamps, and all accessories. Tenders by Nov. 30. Details in our advertisement columns.

Portsmouth.—The Corporation invite tenders for the permanent-way construction and underground feeders in connection with the equipment for electric traction of the tramways in the borough of Portsmouth, and extending to Cosham, Hants. Tenders by Dec. 7. Details in our advertisement columns.

Hornsey.—The Urban District Council invite tenders for 50 cast-iron lamp columns, 25 cast-iron side entrance covers, and 25 telephone pit covers and frames for carriageways. Particulars may be obtained on application to Mr. E. J. Lovegrove, engineer and surveyor to the Council. Tenders by 26th inst.

Leeds.—The Corporation invite tenders for the various works required in erection and completion of buildings in extension of the present electric lighting works in Whitehall-road. Plans, etc., may be obtained from Mr. H. Dickinson manager, Electric Lighting Works 1, Whitehall-road, Leeds. Tenders by Nov. 27.

Wolverhampton.—The Tramways Committee invite tenders for steel stanchions, wrought-iron roof trusses, rolled-steel joists, etc., and other works required at the tramway car depôt. Plans, etc., may be seen on application to Mr. J. W. Bradley, borough engineer and surveyor, Town Hall, Wolverhampton. Tenders by Dec. 3.

Oldham.—The Tramways Committee invite tenders for the supply and erection of the iron and steel work required in the completion of a car depot at Wallshaw, within the borough. Specification, etc., may be obtained from Mr. S. A. Pickering, A.M.I.C.E., borough surveyor, Town Hall, Oldham. Tenders by Dec. 5.

Salford.—The Tramways Committee invite tenders for erection of a car depôt and workshops, covering approximately 11,300 square yards, likewise for about 500 tons of constructional iron and steel work in the roofs, etc. Specifications, etc., may be obtained from Mr. Ernest Hatton, tramways engineer, Town Hall, Salford. Tenders by Nov. 30.

Stockport.—The Tramways Committee invite tenders for the supply and delivery of about 1,050 tons of grooved steel girder tramway rails, fishplates, tiebars, bolts and nuts, points, and crossings. Plans, etc., may be obtained (£3. 3s.) from Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Stockport.—The Tramways Committee invite tenders for the overhead equipment and supply of rail bonds for six sections of their electric tramways, having a total length of about 2 miles 3 furlongs 5 chains double line, and 2 miles 2 furlongs single line. Specifications, etc., may be obtained from Mr. A. J. H. Carter, electrical engineer, or Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Stockport.—The Tramways Committee invite tenders for the laying of the permanent way of their electric tramways, including concrete foundation, but excluding bonding and paving, in six sections, having a total length of about 2 miles 3 furlongs 5 chains double line, and 2 miles 2 furlongs single line. Plans, etc., may be obtained on application to Mr. John Atkinson, A.M.I.C.E., borough surveyor, Central-buildings, Stockport. Tenders by Nov. 24.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul-General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

RESULTS OF TENDERS.

Aberdeen.—The Town Council have accepted the tender of Messrs. Johnston, Lundell, and Co., at £3,990, for a 420-kw. set for the Dee Village electric lighting station.

Grimsby.—The Corporation have accepted the tender of Messrs. Chamberlain and Hookham, of Birmingham, for meters, at £4. 7s. 6d. each for 5, 10, 25, and 50 amperes.

Barnsley.—The Park and Lighting Committee have recommended that the tender of Messrs. Venner and Co., for the supply of electricity meters at £4. 10s. each, be accepted.

Lewes.—The tender of Messrs. Field and Co., of Brighton, at £3,777, has been accepted by the Electrical Power Distribution Company, Limited, for building an electricity generating station.

Bedford.—The tender of Mr. W. Laughton, at £33. 10s. each, has been accepted for building two underground sub-stations on the sites indicated on the plan submitted by the electrical engineer.

Bradford.—Messrs. T. Broadbent and Sons, Limited, Central Ironworks, Huddersfield, were the successful contractors in the recent tender for 30-ton electric travelling crane for the new generating station of this Corporation. The acceptance of this tender is subject to the sanction of the Local Government Board being obtained for the requisite borrowing powers.

Dublin.—A clerical error of £10,000 having been discovered in the totalling of Messrs. Siemens Bros. and Co.'s tender for lighting mains, the tenders now stand as follows:

St. Helens Cable Company	£108,039 15 0
British Insulated Wire Company (accepted)	109,447 10 8
Western Electric Company	113,004 13 9
Siemens Bros. and Co.	113,687 12 1
W. T. Henley's Company	120,965 3 8
Callender's Cable Company	125,542 12 0

Grimsby.—A tender from the British Insulated Wire Company has been adopted. The estimate for mains in Bethlehem and Osborne streets, etc., is £670. 8s. 4d.; at the scheduled prices it is £658. 17s. 1d. The committee will also obtain 100 yards distributing cable, etc., at £31. 5s., including delivery, and three Gilbert arc lamps, as spare arc lamps, at £41, as well as two arc lamps, at £67, for lighting up the central station, with from £8 to £10 extra for wall cases. The tender of Mr. Stephenson, at £69. 11s., for fitting up the offices of the electrical engineer and of the cashier, has been accepted.

BUSINESS NOTES.

TRACTION.

Sheffield.—The service to Harcourt-road is to be started in a few days.

Nottingham.—Trials are being made with the electric cars on the new lines.

Bath.—The City Council have agreed to accept the amended tramway agreement.

Liverpool.—The electric car service has now been opened on the Breckfield-road route.

Crewe.—The Town Council have decided to apply for a tramways order and to proceed with the scheme.

Southall-Norwood.—The District Council are asking the London United Tramways, Limited, to retain the double line in their scheme.

City and South London Railway.—The Company are offering 10,000 new ordinary £10 shares at £5 10s. in connection with the Angel extension of this railway.

Bradford.—The cars on the electrical tramway laid by the Corporation between Thornbury and Stanningley commenced to run for passenger traffic on the 16th inst.

Clydebank.—The Commissioners are about to apply, under the Private Legislation Procedure (Scotland) Act, for a provisional order for the construction of tramways within the burgh.

Columbia Motorcar Co., Limited.—This Company has been registered with a capital of £1,000 in £1 shares, the object being to manufacture, sell, let on hire, and deal in electric motors, cycles, etc.

West Cumberland Electric Tramway.—Application is intended to be made in Parliament in the ensuing session for an Act under the above name, authorising the laying down of tramways or tramroads in West Cumberland.

Colchester.—The Corporation of Colchester have decided to run electric tramways through various important streets, so that the three railway stations in the town may be within easy reach of passengers. The rate will be 1d. for three miles.

Kingston.—A statutory meeting of owners and ratepayers for the purpose of adopting a resolution consenting to the promotion by the Corporation in the ensuing session of Parliament of a Bill for obtaining tramway powers was held on Wednesday.

Sunderland.—Lieut.-Colonel von Donop and Major Trotter made their inspections of the tramways on the 20th and 21st inst. respectively. The second section of the overhead electric tramways of the Sunderland Corporation was opened on the 22nd inst.

Cape Electric Tramways Co.—A bonus of 3 per cent. free of income tax payable to all shareholders registered on Nov. 12, and to the holders of coupon No. 7 attached to share warrants to bearer, will be paid after the receipt of transfer returns from South Africa.

Paddington.—The *Daily Telegraph* says that objection is taken to the proposed construction of a new underground electric railway from Paddington to Victoria, for the reason that the railway might prove a serious danger to the houses in Connaught-square, Hyde Park.

Digitized by Google

Central London Railway.—A Bill is to be presented to Parliament in the coming session to enable this Company to construct a double line from the Bank to a new station to be made under the Liverpool-street terminus of the Great Eastern line. An extension is also proposed at Shepherd's Bush.

North Shields.—Notices have been posted relative to a proposed new line of tramways. The promoters intend to apply to Parliament next session for a Bill to authorise the laying of tramlines from North Shields by way of Willington, Wallsend, Walker, Longbenton, to The Grove, Gosforth.

Electric Vehicle Co. of Great Britain, Limited.—This Company has been registered with a capital of £1,000 in £1 shares, the object being to manufacture, sell, let on hire, or otherwise deal with electric motors, cycles, and vehicles of all kinds, and to carry on the business of engineers, electricians, etc.

Coatbridge.—Notices have been posted along the proposed route of the intention of the Airdrie and Coatbridge Tramway Company to apply to the Board of Trade for a provisional order, to be confirmed in the ensuing session of Parliament, authorising them to lay down and maintain tramways in Old Monkland and Coatbridge.

Lowestoft.—At a meeting of the Town Council on the 28th inst., a resolution will be proposed in favour of the promotion of a Bill to empower the Corporation to construct tramways in a number of streets, and to confirm any agreement made with the National Electric Traction Company, Limited, with reference to the leasing of the proposed tramways, etc.

Chester.—The Town Council have resolved to apply to Parliament for an Act empowering them to take over the Chester tramway undertaking, to adapt it for mechanical traction, and to extend the system beyond the borough boundaries. The price paid by the Council to the tramway company is £18,300, and the rolling-stock is taken at a valuation.

Victoria to Putney.—A Bill is to be introduced for the construction of an underground electric railway between Victoria and Putney. The suggested line of route is under King's-road, on the Middlesex side, beneath the bed of the river to Putney, and under Brewhouse lane and High-street, Putney, as far as Montserrat-road, where the terminus will be situated.

Smethwick.—The Town Council have now concluded an arrangement with the British Electric Traction Company upon the question of the supply of electricity to the borough for lighting and power purposes. Mr. J. G. Aldridge has expressed a favourable opinion upon the agreement, which will probably be brought before the Council for their approval at an early date.

Thames Ditton.—The London United Tramways, Limited, propose to apply to Parliament in the ensuing session for power to construct additional tramways, some of which will be within the Council's district. They propose to follow the usual plan of affixing the notices to the lamp-posts in the streets affected, and the Council have refused to allow the notices to be posted on the lamp posts.

Tettenhall.—At the last meeting of the District Council a letter was read from the borough surveyor of Wolverhampton, who sent plans for the construction of the new electric tramway, showing a single line of rails except at the bottom of the rock and a loop line at the top of it. It was resolved that no double line be allowed in the Board's district, nor loop lines between Henwood-lane and Stockwell End.

Hampstead.—Notice has been given by the promoters of their intention to apply to the next session of Parliament for power to lay a system of electric tramways from Hampstead and North Finchley, running along Finchley-road, Regent's Park road, and Ballard's-lane. There will be no overhead or underground current, the idea being to provide a motive power by means of electric engines attached to the cars.

Chester-le-Street.—The Rural District Council are considering an application from the United Kingdom Tramway and Light Railway and Electrical Syndicate, Limited, for the consent and support of the Chester-le-Street authority for the promotion of a provisional order under the Tramways Act, 1870, for the construction of tramways on the overhead electric trolley system from Penshaw Bridge through Washington and New Washington.

Perth.—At the last meeting of the Council attention was called to a letter from Mr. Dempster, solicitor, intimating that the Commissioners' offer of £20,000 for the purchase of the tramways could not be entertained. The minute was disapproved of, and the matter remitted back to the Tramway Committee. It was thought that if that minute was allowed to stand, and the matter was remitted to arbitration, the minute was bound to affect the arbiter's mind.

Castleford and Normanton.—The Pontefract Town Council are in favour of the proposals of the United Kingdom Tramway, Light Railway, and Electrical Syndicate, Limited, to establish a system of electrical trams in and between Normanton, Whitwood, Castleford, Glass Houghton, Pontefract, Purstone, and Featherstone, and also to supply electric light and energy within those areas. The agreement is to be submitted to a select committee of the Council.

Across London.—Amongst the applications for parliamentary powers, there are two schemes for underground electric railways—viz., the King's-road Railway and the North and South Junction Railway. The King's-road Railway will be three miles long, and will be run from Victoria to Parson's Green, and the North and South Junction Railway will run from Paddington *vid* the Marble Arch, Hyde Park-corner, Victoria, Vauxhall, Kennington-oval, to Kennington Park, a distance of nearly five miles. It is intended to have first and third class carriages on both these lines.

Clontarf.—The resolution passed by the Council authorising the United Tramway Company to construct tramlines from Fairview corner to Ballybough Bridge, and to bond their cables along the Strand-road at certain points with the rails, on payment of an annual sum of £100, and the paving of the vicinity of the stopping place at Fairview corner, has been rescinded, and the Council will sanction the proposed works by the tramway company on their paying the sum of £50 and paving the vicinity of Fairview corner, the payment to commence on the running of the trams.

Leeds.—The Post Office authorities are paying £500 a year to the Tramways Committee of the Corporation for the right of the postmen to travel by the cars. The question of the renewal of the contract was considered at the last meeting of the committee. It had been pointed out by the management that, owing to the largely increased service and greater facilities, an additional sum should be paid by the Post Office. The postal authorities, however, objected to any advance at present, and after discussion it was decided to renew the contract on the old terms for another year.

Grimsby.—At a meeting of the Lighting Committee last week the Chairman said he believed the electric light would be in use in the streets of Grimsby at the opening of the new century, and the electric tramcars by Whitsuntide. The district manager of the National Telephone Company had informed him that he believed the effect of the trams would be to render the overhead telephone wires in Grimsby practically useless, and the company would like to lay the principal mains underground. A discussion ensued as to the advisability of municipalising the telephone system and it was decided to hold a meeting in a fortnight to fully deal with the matter.

Cleethorpes.—The tramways company have had many difficulties to contend with in their attempts to provide the district with an improved and more up to-date service. The latest trouble that has come upon them is in relation to water. It appears that immediately underneath a portion of the new rails in Grimsby-road is a water-main. The waterworks company wish the tramways company to divert the main. The tramways company suggest that the matter be obviated by the waterworks company arranging for junctions to the main wherever there is a possibility of there being any side streets from Grimsby-road. The question is at present under consideration.

Surbiton.—The Urban District Council have adopted a report of the Parliamentary Committee containing the following clauses: "(1) We advise the Council to adhere to their resolution to oppose the London United Tramways, Limited, so as to obtain a *locus standi* on clauses; (2) that the clerk be and is hereby instructed to take the necessary measures to oppose the Bill for tramways now being promoted by the Kingston Corporation, as far as that Bill concerns the areas under this Urban Council; (3) that the terms offered by the London United Tramways Company be accepted, and that the chairman be instructed to give effect to the proposed provisional agreement with the company."

Wigan.—The Council have decided to promote in the next session of Parliament a Bill to enable the Corporation to construct tramways along the following routes: (1) Wigan-lane, Wigan; Wigan-road and High-street, Standish-with-Langtree. (2) Woodhouse-lane, Wigan, and Standish Lower Ground, Standish-with-Langtree. (3) Millgate, Scholes, and Whalley, Wigan. (4) New Market-street, Frog-lane, and Woodhouse-lane, Wigan. (5) Caroline-street, Chapel-lane, Bradford-street, and Bradford-place, Wigan. Powers are also to be sought to enable the Corporation to construct street improvements in connection with the proposed tramways, and, in particular, to widen Whalley, Wigan, and Wigan-road, Standish-with-Langtree. Application is to be made for sanction to borrow £18,250 for tramways.

Middlesbrough.—Major van Donnop, R.E., held an enquiry into several matters between the Imperial Tramways Company and the Middlesbrough Corporation on the 21st inst. The principal question dealt with was whether the company should be called upon to construct the lines and portions of lines which were authorised by the provisional order, but which had not yet been constructed. Life-guards were also discussed. The Inspector said that he would send such suggestions as occurred to him with regard to life-guards and steps to the Corporation and the tramways company. Mr. Clifton Robinson stated that he would be pleased to discuss in a friendly spirit with the Corporation or its representative any suggestion which the inspector might make, or which might occur to the Corporation for increasing the comfort for passengers and safeguarding the general public.

Croydon.—At the meeting of the Rural District Council on Thursday last week Mr. Butterworth, clerk to the Wimbledon District Council, attended and explained the plans to the Mitcham and Merton members. He said that the London County Council proposed to bring their trams as far as Tooting, their system being the conduit system. It would be impossible to bring the conduits over Tooting Bridge, but Prof. Kennedy, the technical adviser to the London County Council, stated that there would be no difficulty in changing from the conduit system to the overhead trolley system at Tooting. The total length of single line would be about 3¾ miles, and a rough estimate of the cost was £7,000 a mile, but that estimate was a very rough one, and did not bind his Council. It was agreed that the portion of line referred to be added to the portion in respect of which the Council had applied for a provisional order.

Digitized by Google

Darlington.—The settlement of the dispute between the Imperial Tramways Company and the Darlington Corporation does not seem to come very much nearer. The Corporation, says the *Leeds Mercury*, strongly object to the terms of the provisional order, and seek to obtain, in accordance with a resolution passed at last Council meeting, a hearing by the Light Railway Commissioners. This, it is understood, they have a difficulty in doing, as there is a strong aversion to the tramways company being allowed to take their own course and deviate so largely from their original proposals. The idea which has been repeatedly mentioned of the Corporation buying the existing tramways and carrying out a new system of electric tramways on their own account begins to find more favour, and the General Purposes Committee are, it is understood, making enquiries with a possible view to such a step being taken.

Tyneside.—Now that the electrical supply companies have got the necessary parliamentary powers to operate on both banks of the Tyne, it is likely, says the *Newcastle Daily Chronicle*, that there will be electric tram services from Newcastle and Gateshead, respectively, to the coast. On the south side Jarrow will be connected with South Shields, and from the mid-Tyne borough it is intended eventually to extend the ways to Gateshead. Now there is the probability of a local company running a service on the Northumberland bank of the river. This is an enterprise contemplated by Tyneside capitalists who, in the next session of Parliament, will seek powers to enable them to construct lines between Newcastle and North Shields. If the necessary sanction is obtained they will purchase the electric energy from the company which is at present constructing electrical works, and therefore the tram scheme will be a separate undertaking. A communication to this effect was laid before the Willington Quay Urban District Council the other evening, and they, together with the other authorities, will most likely discuss the proposal with the company at an early date. It may be said that there is a good train service on the north side, and that the trams are scarcely required; but if cheap fares are adopted, there is no knowing what development may take place. Wallsend will soon be large enough to have a tram service of its own, and the surrounding places are growing rapidly.

LIGHTING AND GENERAL.

Hampstead.—The electric lighting of Fleet-road is being considered.

Cheltenham.—The electrical engineer has prepared an exhaustive report on free wiring.

Finchley.—We understand that electricity for lighting purposes will be available shortly.

Colchester.—The Council on Wednesday decided to apply for a provisional tramway order.

Bedford.—The Urban Sanitary Authority have agreed upon several extensions of cables.

Huntingdon.—The question of public lighting by electricity has been shelved for the present.

Birstall.—The District Council have decided upon their electric lighting route for the compulsory area.

Clydebank.—Application is to be made by the Commissioners to the Board of Trade for a provisional order for electric lighting.

Maidstone.—The Council are urging the Local Government Board about the answer to the enquiry with regard to the electric light.

Barnsley.—The Town Council propose to apply for sanction to the borrowing of £20,000 for the purpose of extension of the electric light plant.

Avon Electricity Meter Co.—The transfer books of the ordinary and preference shares will be closed from the 26th inst. to the 15th prox., inclusive.

Ambroath—Offers by Messrs. Edmundson and by Messrs. Crompton and Co. have been remitted to the Electric Lighting Committee for reconsideration.

York.—The Council has decided to purchase the tramways, the formal resolution for which step is to be moved at a special meeting to be held on Dec. 17.

Worksop.—The Urban District Council have obtained a loan of £5,000 (part of £30,000 proposed to be raised for the purposes of electric lighting) at 3½ per cent.

Paignton.—The Electric Light Committee have discussed with Mr. Singer the preliminary arrangements for the installation of the light. The town is to be canvassed.

Trowbridge.—The Urban District Council will apply for a provisional order authorising them to supply electricity for all public and private purposes in their district.

London Gazette.—The estate of F. Metcalfe, 6, Tenter-lane, Swinegate, Leeds, has been released from trusteeship, also that of W. H. F. Bowman, 8, Foster-street, Gainsborough.

Colne.—Mr. H. P. Boulnois has held an enquiry into the application of the Corporation to borrow £39,000 for the purpose of proceeding with the projected electric lighting undertaking.

Edmonton.—The Urban District Council have rescinded a resolution passed by the Council in favour of applying to the Board of Trade for a provisional order to supply electricity in the borough.

Farnley.—The District Council are making enquiries from other urban councils as to what steps they intend to take with respect to any proposal to supply electric power, etc., to their respective districts.

Standish-with-Langtree (Lancashire).—A report on the electric lighting question is being furnished to the Council by Messrs. Lacey, Clirehugh, and Sillar, Westminster and Manchester.

Sale of Plant.—The Markets Committee of the Leeds Corporation invite tenders for the purchase of belt-driven electric lighting plant now at the Kirkgate Market. Particulars in our advertisement columns.

Heddesden.—The Urban District Council have decided to apply for a provisional order to empower the Council to exercise within their district all or any of the powers afforded by the Electric Lighting Acts.

Ilford.—The sum required by the Urban District Council in connection with the electric lighting works is as follows: to the end of the year, £20,000; to the end of February next year, an additional £25,000.

Cleethorpes.—Mr. C. S. Vesey Brown has submitted three estimates for proposed machinery, cables, and general electrical equipment. No. 1 estimate represented £19,129, No. 2 £20,072, and No. 3 £17,388.

Goole.—The electricity works are now in an advanced state, but the committee are waiting for some lengths of piping which has to be specially made. The date when the works will be opened has not yet been fixed.

Stratford-on-Avon.—The generating station is to be erected on a piece of land belonging to the Corporation situate in Rother-street, and the mains are first to be laid in Greenhill-street, Wood-street, and High-street.

Newbury.—Arrangements are in progress for making an application to the Board of Trade for powers to establish electric light works in this town. The matter is being promoted by a London electric light company.

West Ham.—The Guardians have received sanction to a further expenditure of £1,875 on electric lighting of the West Ham Union and Schools, bringing the total expenditure up to £6,500. The work is to be proceeded with at once.

Crieff.—The Town Council have now resolved to apply to the Board of Trade for a provisional order to have the town lighted by electricity, and it is proposed, on obtaining the order, to lease the lighting to a company to carry out.

London County Council.—The Council intend to ask the North Metropolitan Tramways Company whether they are willing to surrender their lease before its expiry (1910), so as to enable the Council to adopt electric traction on these lines.

Rowley.—It appears that the terms of the provisional order of the Midland Electric Corporation are not regarded as satisfactory by the Council, who propose, if they cannot obtain satisfactory terms, to apply for a provisional order for themselves.

Perfect Light Co., Limited.—This Company has been registered with a capital of £25,000 in £1 shares, the object being to adopt an agreement with the Scott, Snell, Phillips Syndicate, Limited, and M. Lachman, and to carry on the business of electricians, etc.

West Ham.—The Local Government Board are prepared to sanction a further expenditure of £1,875 on electric lighting of the West Ham Union and Schools, bringing the total expenditure up to £6,500. The Guardians have resolved to proceed with the work at once.

Cheadle and Gatley.—The Urban District Council are circularising the ratepayers upon the question of supplying electric light and power. Particulars are to be settled by the chairman and the clerk, subject to the price named being 6d. per unit.

East Africa.—It is reported that an eminent Swiss engineer, who is acting for a French syndicate, has started for Abyssinia in order to superintend the construction of a railway between Jibutil and Harrar, and to establish telegraph lines throughout Abyssinia.

Roundhay.—Application is being made to the Board of Trade for a provisional order empowering the Roundhay and District Electric Lighting Company, Limited, to produce and supply electricity for all public and private purposes within the township of Roundhay.

Wallsend.—At a special meeting of the Urban District Council on the 20th inst. it was agreed that a special conference be held between the Council and the promoters of the proposed electric tram scheme from Newcastle to Tynemouth, *vid* Wallsend and Willington Quay.

General Electric Company of Ireland, Limited.—This Company has been registered, with a capital of £2 000 in £1 shares, to construct, purchase, lease, or otherwise acquire tramways in the counties of Dublin and Wicklow, and to equip and work the same by electricity.

Dover.—The Dover Electricity Supply Company are fitting-up a smoke-prevention apparatus at their works. In addition to the other large schemes for which application is being made to Parliament, a Bill is to be introduced for power to buy up both gas and electricity undertakings.

Woolwich.—We are informed that, owing to the rapid extensions since the Woolwich Lighting Company has been taken over by Messrs. Edmundsons, a second 250 kw. turbo dynamo, complete with surface condenser, air and circulating pumps, has been ordered from Messrs. C. A. Parsons and Co.

Roadway Autocar Co., Limited.—This Company has been registered with a capital of £40,000 in £10 shares, the object being

Digitized by Google

to carry on the business of motor, motorcar, and vehicle manufacturers, owners and workers of patents relating to motorcars and vehicles propelled by mechanical appliances, etc.

British and Foreign Electrical Vehicle Co., Limited.—This Company has been registered with a capital of £150,000 in £1 shares, the object being to adopt agreements with Messrs. S. A. Cobbett, E. W. Hart, and C. E. Lee for the acquisition of the business of the Lecoll Electric Battery Company, Limited, etc.

Birstall.—The compulsory area for the electric lighting has been fixed as from the gates of the gasworks, up Smithies-lane, along Low-lane, around by the National Schools, and back by Bradford-road. The latter portion has been included in view of the possibility of electricity being wanted for traction purposes.

Bromsgrove.—The company which recently obtained an order for the construction of the light railway in Bromsgrove and district are this month applying for an electric lighting provisional order this session, Mr. W. H. Scott, of Bromsgrove, being the solicitor, and Messrs. Pritchard, Green, and Co. the engineers.

City of London.—At the meeting of the Common Council last night it was proposed that the Corporation should create and endow a commercial college, and also that it should defray the cost of lighting the church of St. Lawrence Jewry with electricity. These preliminary discussions are always taken with closed doors.

Berwick.—At the last meeting of the Sanitary Authority the Clerk stated that, in answer to a letter to Edmundsons, Limited, regarding the lighting of Berwick by electricity, for which they had obtained the necessary legal powers, he had obtained a reply, stating that the company intended to undertake the work early next year.

Penybont.—The Council have consented to an application of the Post Office authorities to erect telephone poles from Bridgend to Aberkenfig and Aberkenfig to Brynmenyn, and also to the National Telephone Company to erect posts in another part of the district, subject to an agreement, the charge being 1s. per post per annum.

Cardiff.—A meeting of all classes of local electrical workmen was held on Thursday last week for the purpose of forming a local branch in connection with the Electrical Trades Union. It was afterwards resolved that a branch of the Electrical Trades Union be formed in Cardiff, and rules for the guidance of the branch were adopted.

Stock Exchange.—The Stock Exchange Committee have ordered to be quoted in the official list the Hove Electric Lighting Company, Limited, 11,000 shares of £5 each, fully paid, Nos. 1 to 11 000. The committee have been asked to allow the City of London Electric Lighting Company, Limited, provisional certificates for £200,000 4½ per cent. second debenture stock to be quoted in the official list.

Stirling.—Mr. Hanson has prepared a report on the electric lighting of the Craigs district. He estimates the cost of the lighting of this district as follows: arc lamp pillars, £116; brackets and wall boxes, £17; cable, £80; arc lamps, switches, fuses etc., £120; service boxes, £14; trench work, £40; laying and jointing, £23—total, £410. Mr. Hanson is also preparing a report on the extension of the electric light in other parts of the town.

Bridgwater.—At the last Council meeting a lively discussion ensued with regard to the terms of reference for the appointment of the Lighting Committee, which included the doing of all acts and things that were necessary under the Bridgwater electric lighting provisional order. Several divisions were taken at which the voting was each time level, and the Mayor being a shareholder in the gas company was not able to give a casting vote. Finally, the Lighting Committee was re-elected.

Grimsby.—At a meeting of the Public Lighting Committee last week the question of the municipalisation of the telephone was considered, the chairman referring to an interview he had had with the district manager. It was stated that the electrical service for the tramways would affect the telephone, and a desire was expressed to lay the wires underground. A discussion ensued, from which it appeared that the municipalisation of the telephones, if proposed, would meet with a good deal of support. The matter will be fully discussed at a future meeting.

Plucky Rescue.—A steam-pipe in connection with one of the boilers at the works of the Metropolitan Electric Supply Company burst on Saturday afternoon. An employé who was standing near the pipe was terribly scalded by the escaping steam, which quickly filled the place. Notwithstanding the danger, three of the other workmen dashed into the boiler-house, and, groping around, found their comrade lying prostrate and unconscious on the ground. They took him out, and he was conveyed to the hospital, where he now lies in a critical condition.—*Morning Post.*

Appointments Vacant.—The Guardians of the Bethnal Green Infirmary require the services of an assistant engineer.—The Electricity Committee of the Worcester City Council invite applications for a superintendent of mains. Details of these vacancies appear in our advertisement columns.—A practical electrician is required to take charge of electrical plant of large building, steam power and dynamo. Particulars may be obtained from Mr. F. W. Purcell Alexandra Theatre N.—An assistant engineer, a mechanic, a switchboardman, a stoker, and a boy are required for the electricity works in Grimsby.

Inquest.—On the 21st inst. an inquest was held on the body of R. Edwards, an electrical jointer in the employment of the Cheltenham Corporation. The death of the deceased occurred in a sub station, and evidence was brought to show that he accidentally made contact with the 2,000-volt circuit of a transformer. The medical evidence was that death was due to paralysis of the heart, the result of a shock such as might be occasioned by electric current. The jury returned a verdict in accordance with the medical evidence. They added a recommendation to the effect that the electrical engineer and the Corporation would consider whether some better and more efficient steps might be taken to protect machinery of this kind, so as to prevent a similar accident in the future.

The Electro-Harmonic Concert.—Those members and their friends who attended the Ladies' Night Concert of the Electro-Harmonic Society, held in St. James's Hall Restaurant on Friday evening last, when Major R. E. Crompton presided, were well rewarded for their trouble. An excellent and varied programme was provided, Mr. Alfred E. Izard's renderings on the piano being especially appreciated by musical enthusiasts. The efforts of the Westminster Glee Singers were as usual also accorded hearty applause, and Mr. George Nelson's glassophone solos, not to mention the amusing sketches rendered by that popular humorist Mr. R. A. Roberts, afforded a pleasing variety to the more serious items, instilling a freshness into the programme, which was well sustained to the end.

Newport.—The verdict of the coroner's inquest held on the body of Mr. T. W. Griffiths, who was killed by an electric shock in the Newport electricity works on Saturday last, was accidental death. The evidence was to the effect that the deceased was working behind the switchboard, and that he had neglected to use the indiarubber gloves which he was required to wear by the regulations of the station when working on high-voltage cables. At the time he received the fatal shock he was crouched behind the switchboard, and the marks on the body showed that contact was made with live metal on the switchboard by one knee of the deceased. A post-mortem showed that the deceased's heart and liver were badly diseased, so that a slight shock would have been sufficient to cause death. The verdict of the jury exonerated the management of the station from all blame.

Leeds.—The Leeds Highways Committee on the 21st inst. granted the application of the Corporation Electric Lighting Committee to open out 14 streets at Beeston, Hunslet, and New Leeds for extensions, and also acceded to the request of the same committee for permission to construct transformer chambers in Roundhay-road and Vicar-lane. As preliminary steps towards equipping the Burley and Cardigan-road tramway route with electric traction, arrangements were made for breaking up the ground and laying down feeder wires from the Calls to Headingley by way of Swinegate, City-square, Quebec-street, St. Paul's-street, Park-lane, Burley-road, and Cardigan-road. Victoria-road will be similarly treated. The work of erecting poles for carrying the overhead electric wires between North-street and Meanwood-road and Woodhouse-street has been commenced.

The Electrical Co., Limited.—Some few months ago we gave a description of the new showrooms which have recently been opened by the Electrical Company in Shaftesbury avenue. We have now received three of the new price-lists issued by the Company. The first of these deals with single, double, and treble pole knife switches, of which the Company has a large variety. The dimensions and prices of the switches are given, and also diagrams and illustrations of the same. The other price lists deal with lightning arresters and other safety devices, and with direct-current electricity meters. Of these latter, special diagrams of connections are shown and information given as to the testing, etc. The lists are evidently printed for thumb indexing, as the number of the list and the name of the subject with which it deals is placed so that such an index can be made when the complete number of lists is obtained.

Winchester.—The Sanitary Committee, with the Mayor (Mr. J. Marks), the surveyor (Mr. Anderson), the town clerk (Mr. W. Bailey), and a representative of the firm of engineers, Messrs. Lankaster and Sons, of Southampton, to whom the work was entrusted, recently met at the Corporation pumping station to see the turning on of the electric lighting which has been installed in the building, in the yards, and on the feeding platform of the furnaces. The control of the switches is so arranged that one lamp can be lit in any part, so that there will be no waste. The power is obtained from the waste heat of the destructors, and by this means the new illuminant will cost not more than £10 per annum in excess of the cost of the former lighting apparatus (oil). The members of the party expressed themselves as perfectly satisfied with the work. We are informed that the whole scheme has been carried out at the cost of £275.

Proposed New Bills.—Notices have also appeared, besides those noticed elsewhere, in regard to applications by Brompton and Piccadilly circus (Brompton and Piccadilly-circus Railway Company), Metropolitan District Railway (electrical equipment), Piccadilly and City (company), Bexley (U.D.C.), King's-road (company), City and South London (company), Victoria and City and Southern District (company), West and South London (company), City and North Suburban (company), Charing Cross and Hammersmith and District (company), South Yorkshire Electric Supply (South Yorkshire Electric Power Company). Notice has also been published of the intention of the British Westinghouse Electric and Manufacturing Company, Limited, to bring in a Bill next session to enable them to undertake the electrification of the Metropolitan and Metropolitan District Railways, and to suspend the running powers of the London and North-Western, the Great Northern, the Midland, the South-Eastern, and London, Chatham, and Dover, while the process of conversion from steam to electricity is being effected.

Digitized by Google

William Douglas, Limited.—This Company has been registered at Edinburgh with a capital of £1,000 in £1 shares, the object being to acquire the business carried on under the name of William Douglas, 11, Picardy-place, Edinburgh; to carry on the business of telephone and electrical engineers in all its branches and departments.

Institution of Engineers and Shipbuilders in Scotland.—Vol. xliv., Part 1, of the *Transactions*, issued November, 1900, contains the presidential address by Mr. Robert Caird, LL.D., F.R.S.E., and papers on "A New Gas Producer" by Mr. John A. Purves, D.Sc., F.R.S.E., and on "Marine Engine Shafting" by Mr. J. D. M'Arthur.

Teddington.—Mr. Edgcome, electrical engineer for the Kingston Corporation, has been asked to furnish the District Council with a scheme and report for the purposes of the application by the Council for an electric light provisional order. Mr. Edgcome has obtained permission of his Corporation to prepare the scheme and report.

Croydon.—At the last meeting of the Rural District Council the Clerk read a letter from the clerk to the Wimbledon Urban District Council asking for an interview with the Council in respect of the scheme for laying tramways from Wimbledon to Tooting Permission was given, and plans and estimates were laid before the Finance Committee.

Southend.—At the last meeting of the Town Council the borough engineer's report on the proposed lighting of the town by electricity was agreed to. He estimated that the cost of the installation would be £36,030, and that there would be a profit for the first year of £698. 15s, the income being put at £6,746, and the expenditure at £6,047. 5s.

Lowestoft.—At a meeting of the Town Council on the 28th inst. a resolution will be proposed in favour of the promotion of a Bill to make further provision in regard to the electric light undertaking of the Corporation, and, amongst other things, to empower them to supply electricity in bulk beyond the borough, and to supply electrical fittings.

Long Eaton.—After hearing Mr. Crowther's report on the Mond producer-gas plant and gas-engines last Monday, the Council instructed him to prepare detailed plans, specifications, quantities, and estimates for the Long Eaton electric supply, with a view to applying to the Local Government Board for permission to borrow the sum that may be required.

London Electric Warehouse Co.—This Company has been registered with a capital of £1,000 in £10 shares, the object being to carry on the business of electrical engineers, electricians, suppliers of electricity, manufacturers of and dealers in electrical machinery, plant, and apparatus, producers of light, sound, and power by electricity and otherwise, dealers in iron, indiarubber, etc.

Grangemouth.—The Burgh Commissioners have been advised not to allow any company to obtain electric lighting powers within the burgh, and have informed the North British Electricity Supply Company that they would not consent to their obtaining a provisional order, and that in the event of their proceeding with an application to obtain an order the Commissioners would oppose same.

Skipton.—At a recent special meeting of the Urban District Council a communication was read from the Yorkshire Electricity Supply Syndicate, Limited, who wished to include Skipton in their application to Parliament for a Bill empowering them to supply certain Yorkshire towns with electricity. It was resolved to reply that the Council had themselves decided to apply for a provisional order.

Walton.—In reply to the Urban District Council's notice of intention to oppose their application for a provisional order, Messrs. Edmundson's Electricity Corporation, Limited, have informed the Council that under the circumstances they would not proceed with the order this year, as they were not disposed to undertake the electric lighting of Walton unless they had the support of the Council.

Barnsley.—The Council commenced supplying the electric current on Feb. 17 last, and had 48 consumers equivalent to an output of 380 8 c.p. lamps; on Nov. 20 they had 177 consumers, equivalent to an output of 1,200 8-c.p. lamps, so that they have increased in that short period of about nine months, in every way, about threefold. The borrowing powers being exhausted, sanction for a new loan for extensions is to be applied for.

Victorian Coal.—At the Imperial Institute on Monday, Mr. James Stirling, Government geologist, and mining representative of Victoria, mentioned that in the Latrobe Valley, in Gippsland, alone, he estimated that there could not be less than 31,144,400,000 tons of light-coloured coal, which various analyses had proved to be superior to the average "German brown." Coal extended over an area of 7,000 square miles, and seams 267ft. thick had been found.

Dalkeith.—The Commissioners have under consideration the question of the introduction of electricity into the town in connection with an offer made them by Messrs. Crompton and Co., Limited. By their proposals the town would be supplied with electric light for the streets at a charge of 3d. per Board of Trade unit. The present charge for gas is 4s. 5d. per 1,000 cubic feet, with a reduction of 5d. on the total quantity used for the public lamps.

Carnarvon.—The Town Council have passed a resolution authorising Mr. E. W. J. Peterson, at his own expense in all cases, to apply to the Board of Trade or other proper authority for sole power to construct electric works, and to supply electricity for lighting and other purposes within the limits of the borough of Carnarvon, subject to the order prayed for being submitted to the Council for approval as to details from time to time as occasion may require.

Yarmouth.—At the last meeting of the Town Council the following resolution was proposed: "That the time has arrived when electricity should be substituted for gas in the streets and roads where electric mains have been laid, and that the committee should consider the advisability of extending the mains to such streets and roads as are not now provided with them." The Mayor ruled that the resolution was of such a character as required notice to be given of it.

Obituary.—We regret to have to announce the death of Prof. George Frederick Armstrong, M.A., F.R.S.E., who died at his residence at Grasmere, Westmoreland, on Friday last, in his fifty-ninth year. The deceased has held the chair of engineering in Edinburgh University from 1885 but was unable to be present at the opening of the current session owing to illness. He was for a long period on the engineering staff of the Great Northern Railway, and was professionally associated with railway undertakings in the Isle of Man.

Selsey.—On Thursday last week the installation of electric light was inaugurated at the new Marine Hotel. It is generated on the premises by a 5½-h.p. Otto gas-engine, driving a 4½-kw. dynamo, which in turn feeds 57 E.P.S. cells of the L type, supplying an installation of 110 lamps, the same power being utilised for supplying the tanks with water for domestic purposes. Messrs. Bowerman Bros., of Southsea, have carried out the works, incorporating all the latest improvements in electrical science. The installation is voted a great success.

Mexborough.—The Urban District Council is about to take advantage of an electric lighting provisional order which was secured about 18 months ago. An engineer has been appointed, and the Electric Lighting Committee have worked out the details of a scheme for supplying the town with electricity. The generating station is to be erected on land adjoining Station-lane, where a refuse destructor is also to be placed. The Council has applied for sanction to borrow £13,400 for the purpose, and £4,600 for a refuse destructor, and an enquiry has just been held.

Switchboard Instruments.—We have received from the British Thomson-Houston Company, Limited, a copy of their pamphlet No. 79, which was published on Nov. 7. This pamphlet deals with the Thomson astatic instruments for continuous current switchboards, and information is given concerning their action, and the accuracy with which they are calibrated. Specimens of the dials of the instruments are shown full and half size, and it can be seen that they are easily readable from a convenient distance. A number of illustrations of the instruments are also shown.

Bangor.—The Council have decided to provide an additional engine and dynamo, equal to the supply of 200 kw., owing to the extraordinary demand for the light. It is estimated that 6,000 lights would be required, this being 2,000 in excess of the number the plant is now capable of dealing with. The total amount paid up to date is £15,800, but certain amounts have to be deducted, including about £400 received for land near the refuse destructor. The plant was originally intended to supply 4,000 lights, and 50 consumers were guaranteed. The committee, however, started with nearly 80 consumers.

Blairgowrie.—We understand that the Commissioners are considering an offer from Messrs. Crompton and Co., Limited, by which the company undertakes to pay the Commissioners a sum of £25 annually and one half of profits after 7 per cent. had been distributed to the shareholders; also to pay all costs of provisional order, and give option to take over the undertaking at the expiry of 21 years or at the end of every seven years thereafter at a valuation. The company would utilise the present lamps for public lighting free of expense to the Commissioners, and it was estimated that the annual charge for public lighting would be reduced about £60 or £70.

Tottenham.—A special meeting of the Urban District Council has been held for the purpose of considering a recommendation from the joint committee for the promotion of the joint Bill on the subject of electrical power supply, and if approved to rescind or vary the following resolution passed by the Council on Sept. 18, 1900—viz., "That this Council do apply to the Board of Trade for a provisional order under the Electric Lighting Acts to supply electricity within the urban district of Tottenham." It was decided that the solicitors to the Council be authorised to discontinue the proceeding relating to the application for a provisional order if they deemed it expedient.

Ham.—The Drainage and Highway Committee reported at the last meeting of the District Council that they had had an interview with a representative of the Richmond (Surrey) Electric Supply Company, who intended to apply to the Board of Trade for a provisional order enabling them to supply electricity in various parishes in the Thames Valley, including Ham. The charge for supplying the current would be 6d. per unit. It was stated that Hampton Wick Council has consented to the application. The committee recommended that the Council consent to the application. The Council decided to consent to the application on the understanding that the maximum charge should be 6d. per unit.

Shields.—A syndicate which has recently been formed with a capital of £130,000 propose to apply for parliamentary powers to erect an aerial bridge across the Tyne between the foot of Howard-street, North Shields, and Mile End-road, South Shields. The engineers are Mr. G. H. Godsby, of Westminster, and M.

Digitized by Google

Arnodin, who has constructed several bridges of a similar type. The proposed bridge is to be 200ft. high, with a clear span of 640ft. It will be erected on the principle of a platform suspended by cables, and will provide accommodation for the transit of horses, carriages, tramcars, and 200 passengers. The bridge will be worked by electricity supplied by the Corporations of Tynemouth and South Shields.

Dollar.—At the last monthly meeting of the Burgh Commissioners the Clerk submitted agreement with the electric light company. He said that the alterations which he had suggested had not been given effect to, but he thought the alterations should still be insisted on. One, for instance, was the protecting of the Commissioners against claims from the gas company. His own opinion was that they could have no claim, but he thought they should as well be protected against any possibility of a claim. Another thing he suggested was that a plan of any works which the company proposed to erect in the burgh should be submitted to the Commissioners. It was agreed not to sign the agreement until the alterations proposed by the clerk had been given effect to.

Proposed New Bills.—The following notices of intention to apply for Bills have appeared in the *London Gazette*:—*Electric Lighting:* Northwood and Ruislip (Northwood Electric Light and Power Company, Limited), Wellington, Salop (U.D.C.), Ilkley (A. H. Gibbings), Beverley (Corporation), Neath (Corporation), Notting Hill (Notting Hill Electric Lighting Company), Northfleet (U.D.C.), Aberavon (Corporation), London, alteration and readjustment of the areas of supply (R. H. Wyatt, Westminster, S.W.), Lyndhurst (Lyndhurst Electric Lighting and Traction Company, Limited) Brighton (Corporation), Rhondda (U D C.), East Middlesex (Joint Board of the U.D.C.'s of Edmonton, Enfield, Southgate, Tottenham, and Wood Green), Ebbw Vale (U.D.C.), Cheeham (U.D.C.), Bournemouth (Corporation), Royton (U.D.C.), Ross (J. Parker), Faversham (Corporation), Abertillery (U.D.C.), Burgess Hill (U D.C.), Handsworth (U D C.), Paddington B.C. (Metropolitan Electric Supply Company), Teddington (U.D.C.), Widnes (Corporation) *Electric Tramways and Railways:* Devonport (Corporation), Wrexham (National Electric Traction Company), Brighton (Corporation) Glossop (Urban Electric Supply Company, Limited), Bournemouth (Corporation), Burton-upon-Trent (Corporation), Bury (Corporation), Handsworth (U.D.C.), Hyde (Corporation), Chester (Corporation), Sheffield (Corporation).

Manchester.—The Electricity Committee are at present experiencing great difficulties from the obligation they are under to supply motive power for tramway purposes by specified dates. They hope to be able to supply the current necessary for running the cars on three main roads—Cheetham Hill-road, Bury New-road, and Rochdale-road—on Jan. 1 next. The contractors will work night and day if necessary. Two new engines have been constructed by Messrs. Ferranti, and are in course of erection at the Dickinson-street station at the present time. One of these is practically completed, and has been running on trial. Directly the two additional generators, each of 1,000 h.p., are in full use the committee will be able to quickly proceed with the building and equipment of the station in Bloom-street. That work is far behind, and the committee have no place wherein to put the machinery, which has been ready for months. A sub-committee has been appointed with instructions to devote themselves wholly to the work of getting the new station ready, while another is looking after the new station to be built in Stewart-street. The ground was secured three years ago, but none of it has yet been turned up It is feared, with reference to the agreements made with neighbouring authorities, that the committee will not be able to carry them out within the periods agreed upon. Great changes in the staff will shortly be made. The chief engineer is going next March, and the second engineer has already left, having been appointed chief engineer at Bolton. The superintendent of mains has resigned, and will leave at the end of the year.

Fulham.—At Wednesday's meeting of the Borough Council the Lighting, etc., Committee presented the following report: "We have received a letter from the London County Council, stating that the Parliamentary Committee of the Council have had under consideration the proposal that the Council should promote legislation for empowering metropolitan local authorities to borrow money to enable them to wire consumers' premises for electric lighting purposes, but regret that they are unable to see their way to recommend the Council to promote legislation in the next session of Parliament in the direction indicated. We are informed that in some provincial towns the authorities have undertaken the free wiring of premises, and we have instructed the clerk to write to various councils who have adopted schemes of free wiring, asking them under what powers they have acted and for full details of their schemes." The consulting engineer submitted the following report: "Since the last meeting of the Electric Lighting Committee of the late Fulham Vestry work has been progressing somewhat slowly, both at the station in Townmead-road and in the streets. The Horsfall Company have still to complete the mechanical stokers and the weighman's house, and connect up the water service to their water-cooled dampers. They have also to construct their clinker tramway. The cells have had fires in them for some time past. The General Electric Company have now completed two of the main steam alternators ready for steaming, and will have the third ready this week in all probability. The three exciter sets have been ready for some time. The company is, however, very backward with their pipework and switchboard connections in the station, and also with the cable work in the streets. These matters will delay the starting-up of the station. I am again bringing pressure to bear upon them.'

COMPANIES' MEETINGS AND REPORTS.

ARON ELECTRICITY METER.

Directors: Sir James Pender, Bart. (chairman); G. B. Byng, M.I.E.E; R. E. B. Crompton, M.I C.E., M I.E E., etc; H. Hirst, M I E.E; Roger W. Wallace, Q.C. Managing director in Berlin: Geheimer Regierungsrath Prof. Dr. Hermann Aron; Dr. Julius Juttke.

Report of the directors (with abstract of accounts) to be submitted to the third ordinary general meeting of the shareholders to be held at Winchester House, Old Broad-street, E.C., on Dec. 13 at 3 p.m.

The directors are highly gratified with the result of this year's working, which marks a considerable further improvement on the previous satisfactory progress. The balance to credit of profit and loss for the year ending Sept. 30, 1900, amounts to £23,915. 0s. 10d. To this is added the amount of £2,522. 13s. 11d. carried forward, making a total of £26 437. 14s. 9d. The directors propose to deal with the above available sum of £26 437. 14s. 9d. as follows, which is in accordance with Clause 5 of the memorandum of association of the Company: £7,493. 15s. 2d. for dividend of 6 per cent. per annum on the preference shares, of which an interim dividend of £3,746. 17s. 7d. was paid on April 1 last; £980. 6s. 5d. bonus to preference shareholders of which it is proposed to carry £355 16s. 10d. to the credit of preference shareholders for next year, and to declare an additional ½ per cent. per annum for the present year, thus making a total dividend of 6½ per cent. on preference shares; £15,000 for dividend of 12 per cent. on ordinary shares; leaving an amount of £2,963. 13s. 2d. to be carried forward to next year. The business of the Company continues to prosper, and the outlook is brighter than ever. The Aron meter is being adopted in the principal central stations in the United Kingdom, the Continent of Europe, and the Colonies, and this has necessitated the adoption of means for the extension of manufacturing resources. The Company has successfully competed at the exhibition in Paris, and has obtained the Grand Prix, which is the highest award. Two of your directors (Messrs. R. E B. Crompton, M.I.C.E., M.I.E E., and Hugo Hirst, M.I.E.E.) retire from office by rotation this year, but being eligible offer themselves for re-election. Messrs. Price, Waterhouse, and Co. have acted hitherto as auditors, and offer themselves for re-election.

NEW COMMITTEES.

(*Second List.*)

The following Standing Committees have been appointed:

ABERYSTWYTH.—*Public Lighting*: Messrs. R. Peake, C. M. Williams, J. Jenkins, I. Hopkins, J. P. Thomas, J. T. Davies, and G. F. Roberts.

ASHTON.—*Highways and Tramways*: The Mayor; Aldermen Heginbottom, Hulme, Marland, and Siddall (chairman), Wilson; Councillors Andrew, Fletcher, Grime, Hall, Kelsall, Newton (deputy chairman), Oldham, Pollitt, J. Pownall, and Whitehead, Wilkinson, Yoxall, Catlow. *Electricity*: The Mayor; Aldermen Andrew, Hilton, Marland, Siddall, Wilson; Councillors Andrew, Barlow (chairman), Catlow, Grime, Hall, Kelsall, Newton (deputy chairman), Oldham, Phillips, Yoxall, A. Shaw, Wilkinson, and Brrrett.

BARNSLEY.—*Park and Lighting*: Aldermen Holden and Wray; Councillors Brady, Atkinson, Carter, Charlesworth, Foulstone, Maddison, and Rose.

BASINGSTOKE.—*Lighting*: The Mayor; Alderman Smith; Councillors Edney, Burberry, Hillary, Gerrish, and Kingdon.

BIRMINGHAM.—*Tramways*: Alderman Beale, chairman.

BLAIRGOWRIE.—*Lighting and Cleansing*: Ex-Bailie Hill, convener; Messrs. H Quin, J. L. Ford, and A. W. Bennett.

BOLTON.—*Electricity*: Councillor Dr. Panton, chairman; Councillor Berry, vice-chairman. *Tramways*: Alderman Nicholson, chairman; Councillor Smith, vice-chairman. A list of the other members was given in our last issue.

BO'NESS.—*Lighting*: Messrs. Calder, Thomson, Law, Welsh, Barrowman, and Grant (convener).

Digitized by Google

BOOTLE —*Electric Power and Lighting*: The Mayor; Aldermen Brewster (chairman), McMurray (deputy-chairman), Mack, and Morton; Councillors J. Blundell, Brown, Hall, Pearson, Rafter, Westerton, and Wilson.

BOURNEMOUTH — *Tramways and Parliamentary*: Aldermen Davis and Mattocks; Councillors Abbott, Allen, Beckett, Gunning, Hoare, Mate, Stockley, Roker, and Webber. *Lighting*: Alderman Davis; Councillors Beale, Beckett, Cory, Frost, M.D., Gunning, Hoare, Lane, Mate, Parsons, Robson, and Stockley.

BRADFORD.—*Electricity*: Mr. T. H. Shaw, chairman; Mr. J. Akam, deputy.

BURNLEY.—*Tramways*: Alderman Armistead, chairman; Alderman West, vice-chairman. *Electricity*: Councillor H. Emmott, chairman; Councillor Beecham, vice-chairman. *Electricity Sub-Committee*: Councillor Bibby, chairman.

BURY.—Last year's committees have been reappointed.

BURY ST. EDMUNDS —*Electric Lighting*: The Mayor and Alderman Lake.

COVENTRY.—*Electric Light*: Messrs. Calcott, Slaughter, and Webster.

DERBY.—*Electric Lighting*: Aldermen Ann, Bennett, Fletcher, and Woodiwiss; Councillors Butterworth, Eaton, Foster, Haslam A Ottewell, Simpson, and Wilkins. *Tramways*: Aldermen Doherty, Duesbury, Fletcher, and Spriggs; Councillors Butterworth, Dean, Eaton, Gandy, Johnson, A Ottewell, and Wilkins.

DUKINFIELD.—*Electric Lighting and Traction*: Councillor Wood, chairman; Aldermen Pratt and Pickup; Councillors Cooke, Kenyon, McFarlane, Grime, Ashworth, Cooke, Bardsley, Booth, Heathcote, and Whitehead.

EXETER.—*Electric Lighting*: Messrs. Domville, Hawke, Hodson, Jarman, Munro, Perry, Reid, T. B. Rowe, Stocker, Taylor, Kelland, and Wreford.

FALMOUTH —*Lighting*: Messrs. Thuell, E. A. Banks, E Williams, Grose, and Bullen.

FULHAM.—*Lighting, Electric Lighting, and Dust Destructor*: Mr. T. Davies, chairman; Mr. R. Harris, vice-chairman.

GREENOCK.—*Electricity*: Bailie Cameron, convener; Mr. John Anderson, vice-convener.

HACKNEY.—*Electric Lighting*: Messrs. E. H. Bassett, Berry, Beurle, Coles, Denham, Hasemer, Howitt, Lashmar, Penfold, Richmond, Sheehan, Steel, Watford, Wells Holland, Whiter.

LIVERPOOL —*Electric Power and Lighting*: Mr. S. W. Higginbottom, M.P., chairman; Mr. R. Dart, deputy.

LUTON. -*Electric Lighting and Power*: The Mayor; Aldermen Huckleby and Smith; Councillors Wilkinson, Cumberland, Jennings, Staddon, Ordish, and Garrard.

LYNN.—*Electric Lighting*: The Mayor; Alderman Jermyn and Miles; Councillors Affleck, Carpenter, Chatterton, Floyd, Miles, Sadler, and F. W. Savage.

NEWARK.—*Lighting and Fire Brigade, and Castle Gardens and Playgrounds*: Aldermen Smith, Crossley, and Harp; Councillors Davy, Harston, Perfect, Hatter, Lacy, Milthorp, Slater, Heming, and Doubleday.

NEWBURY.—*Watch and Lighting*: Alderman Lucas; Councillors A. Jackson, Davis, Stradling, and Wigington.

SHREWSBURY. — *Lighting*: Aldermen Cross and Herbert; Councillors Brace, Crump, Deakin, Downes, How, Froggatt, and Withers.

SOUTHEND.—*Light Railways*: Alderman Brightwell, Burrows, and Dennis; Councillors Allen, Berry, Doody, Hudson, Jones, Martin, Millican, Roberts, and Wilkinson.

SOUTHWARK.—*Electric Lighting*: Aldermen Haynes, Hawkins, Mather, Redman, and Vernon; Councillors Bryan, Chell, Attenborough, Edwards, C. Hibble, Hilton, Revitt, Sharp, Wagner, and Hamel.

SURREY C.C.—*Lighting*: Councillor Sprunt has been added to last year's committee.

SWANSEA —*Electric Lighting*: Aldermen Gwilym Morgan, Howel Watkins, Wm. Evans, and David Harris; Councillors J. H. Lee, Thomas Freeman, Odo Vivian, David Williams, A. Sinclair, E. G. Protheroe, B. Freedman, David Jenkins, T. Merrells, George Payne, W. H. Morris, Griffith Davies, H. A. Chapman, Richard Martin, and Morgan Tutton.

WAKEFIELD.—*Electric Lighting*: Alderman Bolton; Councillors Childe, Cradock, Driver, Fallas, Hammond, Harrison, Judge, Rhodee, W. H. Smith, Wigham (chairman), and Powell (vice-chairman). *Street Lighting*: Councillors Driver, Harrison, Hudson, Judge, McInnes, Saville, S. Smith, W. H. Smith, and Ramsden (chairman); Alderman Harrap, vice-chairman.

WANDSWORTH.—Until the Highways, Sewers, and Lighting Committee is appointed, the representatives of each district will act as local committees.

WIGAN.—*Electric Light and Tramways*: Councillor T. Worthington, chairman; Councillor G. Sutherland, vice-chairman; the Mayor, the ex-Mayor, Messrs. T. Ashton, J. Ballard, W. J. Lamb, J. Hilton, R. Layland, W. Livesey, J. Paxton, S. Taylor, S. Wood, and R. Richards.

WORCESTER. — *Electricity*: The Mayor; Mr. Maund, high sheriff; Aldermen Millington, Ernest Day, Holland, Harry Day, Perrins, and W. Caldicott; Messrs. Campbell, Darling, Kershaw, Cook, Parker, Williams, Kay, and Gray.

PROVISIONAL PATENTS, 1900.

NOVEMBER 12.

20311. Improvements in electrical cushions for tables and the like Oscar Thomas Banks, 49, Mortimer-street, Cavendish-square, London.

20357. An improved self-contained portable electric lamp. James McHardy, 38 Chancery lane, London.

20362. Improvements in renewing the filaments of electric incandescent lamps Charles Howard, 70, Palace-chambers, Westminster, London. (Complete specification.)

20383 Improvements relating to alternating-current induction motors. Benjamin Garver Lamme, Westinghouse-building, Norfolk street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, April 14, 1900, being date of application in United States.)

20384 Improvements relating to systems of electrical distribution. Benjamin Garver Lamme, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, April 14, 1900, being date of application in United States.)

NOVEMBER 13.

20439. Improvements in electric fire-alarms. Oscar Freymann, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

20466. Improved electric apparatus for exploding mines. Evershed and Vignoles, Limited, and Sydney Evershed, 1, Queen Victoria-street, London.

20471. Improvements in or relating to connectors for electric wires and the like. John Rymer Jones, 111, Hatton-garden, London. (Complete specification.)

NOVEMBER 14.

20493. Improvements in and appertaining to distributing boards for electrical circuits. Alexander Munro Taylor and Robert Steel, 141, West George-street, Glasgow.

20507. Improvements in sparking plugs for electrically-fired internal-combustion engines. Robert Frederick Hall, 24, Temple-row, Birmingham. (Complete specification.)

20510. An improved vacuum tube for X-ray production. Alfred Ernest Dean, 73, Hatton-garden, London.

20522. Improvements in high-potential line switches for electric currents. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett, United States) (Complete specification.)

20540. Improved device for indicating the movements of a mariner's compass. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

20558. Improvements in and relating to combined telephone and electric bell circuits. The Berliner Telephone Manufacturing Company, 322, High Holborn, London. (Joseph Berliner, Germany.) (Complete specification.)

20573 Improvements in electric controllers. William Horatio Harfield, 4, South street, Finsbury, London.

20576. Improvements in apparatus for signalling by wireless telegraphy. John Ambrose Fleming and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery-lane, London.

NOVEMBER 15.

20590. Certain improvements in carriers for portable electric cables in combination with holder for lamps. Richmond Smith, 47, Chester-street, Birkenhead.

20631. Improvements in automatic electric carriages and appliances for the transport of light goods or traffic. Hans Dubs and Léon Laffitte, 65, Chancery lane, London.

NOVEMBER 16.

20662. Cap or cover for the handles of brakes on electric and other cars and machinery. Charles Symes, Ellerslie, West Derby, Liverpool.

20707. Electric exercising machine. Michael Bartholomew Ryan, 12, Salomonsgasse, Cologne.

NOVEMBER 17.

20757. Improvements in apparatus for generating pulsative constant electric currents. Edmund van Haanen, 4, Corporation-street, Manchester.

20758. Improvements in machines for generating constant electric currents. Edmund van Haanen, 4, Corporation-street, Manchester.

20761. A new method of constructing electrical cells of the Leclanché type. Digby Francis Baynes Cotes, 62, Union-street, Burton-on-Trent.

20764. Improvements in shade fittings for incandescent electric lamps. Arthur Albert Guest, 24, Temple-row, Birmingham.

20765. Improvements in or relating to electric lampholders. Clifford William Kemp, 24, Temple-row, Birmingham.

20778. Improvements in electric arc lamps. John Allen Heany, Norfolk House, Victoria-embankment, London. (Complete specification.)

20779. Improvements in electric arc lamps. John Allen Heany, Norfolk House, Victoria-embankment, London. (Complete specification.)

Digitized by Google

29797. Improvements relating to sound-magnifying appliances for telephones, phonographs, and the like. Otto Rieger, 36, Chancery-lane, London.

29809. Manufacture of a primer for producing ignition by electricity. Richard Kändler, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

29808. Improvements in or connected with electrical burglar alarms. John Henry Pennington and Virgil Yates, 55, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Dec. 8.

1899.

18664. Electric railways on closed-conduit systems. Purvis.

22089. Electric tramways or railways on the slotted-conduit system. Hewer.

23315. Electrolytic meters. Wright and Mutual Electric Trust, Limited.

23316. Electrolytic meters. Wright and Mutual Electric Trust, Limited.

24138. Coin-controlled electric meters for motors or the like. British Thomson-Houston Company, Limited. (Holmes.)

24960. Method of producing electrodes for electrical accumulators. Luckow.

24968. Process for the production of thermo-electric batteries. Jonas.

25576. Resistance switches and automatic cut-outs for starting, regulating, and protecting electric motors and their circuits. Veritys, Limited, and Steele.

1900.

400. Electric arc lights or lamps. Lee.

10210. Electrical apparatus for closing steam-supply valves from a distance and giving an audible signal. Dahl.

10176. Adjustable electric igniter or spark producer for motors. Braun.

10606. Electrical fuse boxes. Smith.

13613 Wireless telegraphy. Maréchal, Michel, and Dervin.

14769. Coin-freed apparatus for the supply of electric power. Lake. (Earle.)

14913. Switchboards for telephone stations. Baird.

15312. Apparatus for stopping, starting, and reversing electric motors. Wise. (Skodawerke Actiengesellschaft.)

16082. Combined reversing switch and automatic maximum current interrupter for multiphase current motors. De Kandó.

16290. Electric circuits for the transmission of energy by variable currents. Campbell.

16408. Electrodes of electro-chemical accumulators. Von der Poppenburg.

16704. Adjusting brush-holders for electric machines. British Thomson-Houston Company, Limited. (Reist.)

18175. Advertising clock either combined or not with an electric alarm or call. Royer.

NOTES.

The Electrical Engineers Volunteers.—We are pleased to note that the Secretary for War has approved of the corps of Electrical Engineers Volunteers borrowing £6,000 from the Public Works Loan Commissioners for the construction of headquarters buildings. From this it will be seen that the value of the corps appears to be fully recognised in official quarters.

Alaskan Cables. — Telegraphic communication has now been established between Nome and St. Michael's. The cable in question was laid by the Alaska Commercial Company, who used the side-wheel steamer "Sadie" as a cable ship. The charge for transmission of messages over this line is 8s. 4d. for 10 words. The new line will be of great value to North Alaska. It is reported that the telegraph line from Skagway down the Yukon to Dawson is nearly completed, but will not be open for traffic this winter.

Milking Boosters. — The *West Sussex Gazette* is responsible for the following interesting note: "What is a 'milking booster'? Some members of the Worthing Corporation are curious to know. They have ordered two for their electric light undertaking, and don't believe in buying pigs in pokes. The chairman of the special committee was asked for a definition. He says a 'milking booster' occupies the same position at electric lighting works as champagne at a public dinner. A prominent teetotaller who sits on the Council thinks that, if such is the case, the town might spend their money much more profitably than on 'milking boosters.'"

The Manufacture of Cordite.—The Government of India, having recognised the greater advantage and safety of electricity in the manufacture of cordite, have, we learn, recently advertised for tenders for the supply of a complete electrical installation at their cordite factory in the Nilgivi Hills. The power is to be obtained from one of the numerous waterfalls in the neighbourhood of the factory, and the generator is to have about 500 kw. capacity. The installation is to include a complete plant of generators, motors, transformers, cables, transmission line, etc. The distance over which the power will have to be transmitted is about three miles. An hydraulic plant is also to be installed, the power which it will be required to develop being equal to 500 h.p. from a waterfall about 600ft. in height.

The Negro Question.—The recent attempt made in the New Orleans City Council to pass a street-car regulation to provide for the separation of negroes and whites in the tramcars of the town, shows how strong is the feeling over the negro question in certain parts of the States. The attempt was abandoned, and we are informed by the *Electrical World* that it has been tried without success in other southern towns. The usual effect was to prevent negroes from travelling on the cars, thus causing considerable loss of revenue. There was also the difficulty that a white man would not wait if he was in a hurry, but would board a car reserved for negroes only. The greatest trouble, however, seems to have been that the conductor of the car was made responsible as to the colour of his passengers. Reading between the lines, we suppose that errors of judgment were likely to lead to funerals.

Electric Belts.—The following is an extract from the *Lancet* of last week, and raises the question as to whether an advertisement constitutes a warranty: "In the Westminster County Court on Tuesday last, before Judge Lumley Smith, Messrs. Pulvermacher, Limited, electric belt makers, of Regent-street, W., brought an action for four guineas, the balance of the purchase money of an electric belt supplied to Mr. H. Mott, of Oxford. Mr. Mott was led to write to Messrs. Pulvermacher by advertisement, and paid one guinea on account of a five-guinea belt described as 'doubly concentrated.' The belt in no way relieved his symptoms of migraine and irritability, but rather, in his opinion, made him worse. So he returned it. Judge Lumley Smith held that the advertisement of their belt issued by Messrs. Pulvermacher was a warranty to cure 'all the ills that flesh is heir to.' As the defendant was not benefited by the belt, he found in his favour, but did not give him costs."

London Electric Lighting Committees.—We are pleased to see that the new metropolitan borough councils are, in the election of their electric lighting committees, striving to preserve a certain amount of continuity. We think we can safely say that in every case where possible the members of the old vestries who served on the electric lighting committees have been placed on the similar committees of the new councils, if they were qualified by election. Of course, with the great reduction in the number of representatives, a number of old electric lighting committee men have fallen out of office. We are very pleased to note that the electric lighting committees are being reduced in number; sometimes this reduction is nearly as much as 50 per cent. We are quite sure that the smaller committees will be much more efficient than the old vestry committees used to be. A small working committee is much less likely to fall into personal wrangling than is a large one, in which there is no actual work for the great majority of the members to do.

Automobile and Cycle Exhibition. — We are informed by Mr. G. Rives, the president of the organisation committee, that an international exhibition of automobiles and cycles is to be held in Paris early next year. The exhibition is being organised by the following associations jointly: La Chambre Syndicate du Cycle et de l'Automobile, La Chambre Syndicate de l'Automobile, Le Syndicat des Fabricants de Cycles, Le Syndicat Français de l'Industrie General des Cycles, and the Automobile Club de France. All these have joined in promoting the success of the exhibition, which will be held in the Grand Palais des Champs-Elysées. The exhibition is to open on Jan. 21, and will last until Feb. 17, 1901. Applications for space will be received up to Jan. 3, and on Jan. 8 the various positions to be allotted will be determined by ballot amongst the various applicants. We think this is an exceedingly fair way of deciding who shall have the more prominent places. All communications should be addressed to the Commissionaire Général, Automobile Club, 6, Place de la Concorde, Paris.

Electrical Engineers Volunteers.—We are pleased to hear that the Electrical Engineers (Royal Engineers) Volunteers are organising a dinner to their South African detachment, which is soon expected home. All being well, the dinner will be held at the Trocadero Restaurant on Saturday, Dec. 15, and it will be followed by a smoking concert. The South African detachment will, of course, be the guests of the evening. The committee having the matter in hand are: Messrs. R. S. Erskine, major commanding E.E.R.E.V.; S. B. Marshall, Q.M.S., hon. treasurer; G. A. Poynton, C.S.M., chairman; and H. A. Barnett, sapper, hon. secretary. On the Monday following, another dinner in the Prince's Restaurant is to be given to the detachment, which dinner is being organised in the same way as the send-off dinner. Mr. Henry Edmunds, of 2, Queen Anne's-gate, is hon. treasurer, and will be glad to receive the names of gentlemen who wish to act as hosts in place of any of the original hosts who may be unable to attend.

Digitized by Google

The subscription of each host, covering the cost of his own dinner, inclusive of wine, will be two guineas.

Acetelyne Flame as a Standard.—An interesting paper on the above subject by Dr. E. N. Nichols appears in the Franklin Institute's *Journal*. The author has undertaken a vast amount of work in order to prove the advantages and disadvantages of the acetelyne flame as a standard for photometric work. The whiteness of the flame makes it a very suitable standard to compare arc lamps with. The author, however, shows that the gas loses its illuminating qualities when stored, and that the illuminating qualities are largely dependent on the construction of the generator in which the carbide of calcium is converted into acetylene—*e.g.*, he shows that in one case acetylene gas was stored for five months in a gas-holder over water, and that at the end of that time it only retained 6 per cent. of its illuminating properties. He also found that the gas obtained by what is known as the wet process, was much more efficient as a light giver than that produced from the dry process. In spite of these drawbacks, Prof. Nichols thinks that good use may be made of the acetylene flame if simple precautions are taken.

Electric Fire Risks.—It is a curious thing that the same week that the editorial on the dangers of the electric light appears in the *Lancet* we should receive from another source a pamphlet on "London Fires and the Electric Light." This is prepared by Mr. John Bate, of Hammersmith, and contains extracts from the annual report of the London Fire Brigade for 1899. These extracts show that there were 312 fires caused by the use of gas, 292 fires from the use of oil lamps, and 18 fires from the use of the electric current. Mr. Bate also calls attention to the fact that there is a great increase in the use of electricity during the year, which, with a corresponding increase in the risks in view of the above figures, he considers should induce insurance companies to reduce their heavy risk rates upon warehouses, factories, and shops where electricity is the illuminant. With a view of bringing pressure to bear upon these companies to that end, he suggests that combined insurance by corporations should be started. We would commend this pamphlet to the editor of the *Lancet*, and wonder how he will be able to reconcile it with his opinion so publicly expressed.

Institution of Electrical Engineers.—We hear from the secretary of the Institution of Electrical Engineers that if the discussion on Mr. Langdon's paper on "The Supersession of the Steam by the Electric Locomotive" was not completed last night, another special meeting is to be held next week. The Institution of Mechanical Engineers have kindly offered the use of their lecture theatre again for Thursday, Dec. 6, when the discussion would be resumed. We also hear from the secretary of the Students' Section of the Institution of Electrical Engineers that the visit of students to the electrical laboratory of the Board of Trade is intended for those who are not attending any London technical colleges. The number of a party who will be shown over this laboratory is strictly limited to six. Mr. L. R. Lester, the honorary secretary of the Students' Section, therefore requests that applications from those who wish to attend this visit should be sent in before the 6th proximo. The laboratory itself, situated at 8, Richmond-terrace, Whitehall, is well worthy of a visit, and we shall be surprised if the applicants do not amount to several times the number which can be admitted.

Bradford Electricity Department.—On the 16th inst. the first smoking concert in connection with the Bradford Corporation electricity department was held at the Queen's Hotel, under the chairmanship of Mr. R. H. Chattock, the electrical engineer of Bradford. The employés of the department were responsible for the programme, which was a very extensive one, including no less than 22 items. Mr. A. H. Gibbings, the late electrical engineer of the town, took the vice-chair, and a number of the Electricity Committee were also present. All classes of the employés of the department were represented, but all could not be present, as all were not free from duty at the time the concert was held. Other two concerts are being arranged in order that every member of the staff shall have an opportunity of being present. The works at Bradford are now so large that it is necessary to run three shifts, and this is the only way that the concert committee were able to ensure that all members of the staff should have an equal chance of deriving benefit from the entertainment. The annual subscription is fixed at 1s. Undertakings like this do much to promote friendship amongst the staff, and are, in consequence, to be highly recommended.

American Electro-Therapeutic Association.—We have received from the secretary of the above the list of officers of the association for the ensuing year. These appointments were effected at the tenth annual meeting held in New York in September last. The president is Dr. Ernest Wonde, while Dr. F. H. Morse is the vice-president. The secretary is Dr. G. E. Bill. The offices of the association are at 17, South Third-street, Harrisburg, Penn. We notice that the association has appointed a good number of committees for the ensuing year, and we should say that the idea is a good one if the gentlemen will give up any considerable amount of time to the subjects on the committees concerning which they are appointed. There is a committee on induction coils and alternators, another on electrodes, a third on meters. Amongst the list there are also other sub-committees on static machines and condensers, on electric lighting apparatus for diagnosis, etc., on cotopheresis, on constant-current generators and controllers. The remaining four committees deal more with the internal arrangements of the society itself. The long list of names makes one rather inclined to doubt whether in England an equal number of medical men could be found to give up their time to the advancement of electro-therapeutic treatment.

Sir William Preece on Telegraphy.—On Monday last Sir William H. Preece delivered a lecture in the new physical laboratories at Owens College, Manchester, taking for his subject "Intercommunication by Means of Electricity." This lecture is the fourth of a series which have been arranged at Owens College to illustrate the principal advantages which have been derived from physical science during the nineteenth century. Sir William Preece's name and reputation as a successful lecturer resulted in a crowded room, a number of those present being unable to find seats. The lecture, which was ably delivered, covered the history of the telegraph from its earliest days. The credit of discovering the principles of the telegraph was given to Faraday, and Sir William Preece proceeded to detail the various stages of improvement which had been made since the first line was set up on the London and North-Western Railway between Euston and Camden Town. The telephone was also alluded to by Sir William, who gave statistics as to the growth of this, and also of the increase of telegraph messages during the last 50 years. He showed how the various duplex, quadruplex, and multiplex systems of telegraphy had enabled the line wires already erected to be used for a largely extended service. The last portion of the lecture was devoted to wireless telegraphy, but Sir

Digitized by Google

William Preece's views on this are so well known to our readers that we will not refer to those details.

The Bucking of Large Shunt-Wound Motors.—There being comparatively few shunt-wound motors in use of over 100 h.p., the action of such large machines is not at all familiar to electricians. The Metropolitan Street Railway of Kansas City, however, uses a 300-kw. motor which operates cable machinery pulling about 24,000ft. of cable. There are two motors of this size, one being held in reserve. When the company built its new power-house it was reckoned that a considerable amount of money might be saved by doing away with the steam plant which was then running the Ninth-street cable, and which was proved to be very uneconomical, and operating the cable by electric motors supplied with current from the new central station. When the motors were installed, however, a great difficulty arose in connection with them. The load on the tramway service was naturally very variable, and when sudden loads were thrown on, the motor promptly bucked and sparked considerably at the commutator. The difficulty was so great that had not a remedy been found for it electrical driving would have had to be discontinued. The remedy consisted in the use of a series winding on the field magnet of such direction as to strengthen the fields with increasing load on the motor. The result of this winding is that the motors are almost sparkless in running, and give no trouble from bucking. The phenomenon of "bucking," according to Mr. C. Grover, the company's electrician, is caused in the following way: The brushes are, of course, set at sparkless position for light loads. When the sudden heavy load comes on, the great rush of armature current tends to overbalance the field magnetisation, which is constant, to such an extent that the field flux is greatly distorted. So much is this so that the effect is the same as if the brushes were suddenly taken away from the neutral point, in consequence of which the machine bucks.

Porto Rico Telegraphs.—At the next regular session of the United States Congress the question of the telegraph and telephone service in Porto Rico will probably be taken in hand. The need for a thorough overhauling of both systems is great, as, when the place was taken over by the Americans after the Hispano-American war, the service was in a most dilapidated condition, and it was only owing to the great efforts made by the Army Signal Corps that communication was at all possible between the various important points on the islands. The Army Signal Corps still have the lines under their charge, and General Greely, chief signal officer, has, in a report addressed to the chairman of the Committee on the Pacific Islands and Porto Rico, made several suggestions as to their disposal. In his report General Greely gives an outline of the history of the telegraphic and telephonic undertakings in Porto Rico. Thus, in November, 1866, after some five years of consideration of the estimates, the construction of the lines was started, and after 14 years from the first movement towards obtaining a service—*i.e.*, in 1874—the service, with about 800 miles of lines, was completed. This service was the one in operation when the Americans came on the scene, and the work was taken over by the Signal Corps. Working with the Signal Corps would naturally be the cheapest method of operation, but owing to a cyclone and to the small amount of business done, the lines have not paid their expenses. General Greely thinks that there are three courses open for the disposal of the lines. The first is the operation of the lines by the Post Office, as was done by Spain in the past; the second, the transfer of the lines to the insular Government, with a view to their operation and maintenance at the expense of Porto Rico; and the third, their operation and maintenance, as at present, as military telegraph lines. The first and second plans do not recommend themselves to General Greely, as they would both entail a large expenditure of the public money of the United States, but the third method seems to him the easiest and most natural solution of the question, as Porto Rico must be garrisoned by regular troops, and as it is a detached island, it is desirable to have the telegraph and telephone lines in the hands of the army. The sale and condemnation of lines which are not of military importance and of no real public value, would then gradually be carried out.

Berlin Electricity Works. — The progress of electric lighting and power in Berlin continues apace. During the financial year just ended, the Berlin central stations proper have alone generated an aggregate of 52,014,612 units of electrical energy, which represents an increase of 53 per cent. over the figures for the previous year. The number of consumers has increased from 6,093 to 6,683, the latter representing a connection of 303,304 incandescent lamps, 12,396 arc lamps, 4,964 motors, and 676 miscellaneous current-consuming apparatus, or a total equivalent of 36,350 kw. Compared with the figures for the previous year, the actual increases have been 35,100 incandescent lamps, 1,384 arc lamps, 1,106 motors, and 109 miscellaneous apparatus, or a total equivalent of 4,920 kw. The Berlin tramways accounted for a further 8,000 h.p. of the energy generated. The demand for lighting, power, and tramway purposes represented respectively 28, 24, and 48 per cent. of the total output accounted for. For supplying the outlying suburbs of Berlin, two stations, situated respectively in Spandau and Pankow, have been erected, in addition to the Oberspree works. From these stations current is distributed to 13,080 incandescent lamps, 915 private arc lamps and 800 motors, representing an aggregate output of 6,322 h.p., besides to 1,245 incandescent lamps and 34 arc lamps used for public lighting, these several items not being included in the figures relating to the supply in Berlin proper given above. The prevailing high price of fuel has given rise to the serious consideration of an increased scale of charges for motor power in Berlin, but it has been decided to refrain for the present from such a step in anticipation of an early drop. How seriously a rise in the price of electrical energy for power purposes in Berlin would affect local industries may be judged from the very large number of motors connected. Large extensions of plant are in progress at several of the generating stations, and in this connection it is interesting to note the very large unit of plant which has been generally adopted for these extensions. Of three new 4,000-h.p. steam alternators for the Oberspree works, two are already running, while the third is nearly completed. Three sets of similar capacity are being mounted in another of the stations, while a fourth set is on order for each. The machines, it may be mentioned in conclusion, are being supplied by the Allgemeine Elektricitäts-Gesellschaft.

Society of Arts.—At the opening meeting of the new session of the Society of Arts, held on Wednesday week, Sir John Evans, K.C.B., F.R.S., delivered his inaugural address. He chose for his subject "The Origin, Development, and Aims of our Scientific Societies." He showed that the earliest records of the collective action of individuals for the promotion of science showed that amongst the Greeks and Romans there were colleges formed with this object. The guilds of the Saxon times and the livery companies of London also acted somewhat as scientific societies, as they were formed to promote special trades and industries. The first learned society in England to

Digitized by Google

receive a Royal charter was the Royal Society, which was incorporated in 1662; the Society of Antiquarians had a later history, dating back to 1572, but this society had not had a continuous life. Sir John Evans showed that these earlier societies partook rather more of the nature of clubs than did the societies of the present day. Some interesting facts were culled from the records of the early years of the Royal Society after its incorporation, in order to show what great progress had been made since then—*e.g.*, at that time magnetism and electricity presented almost untrodden fields; the variation of the compass had indeed been observed, but little else was known about terrestrial magnetism. Sir John Evans proceeded in his address to sketch the inauguration of the present Society of Arts and the formation of the various other scientific and engineering societies, which were in their early days intimately connected with one or other of the three above-mentioned societies. There was no doubt, he held, that individual effort could not do alone what the collective efforts of a number of individuals interested in the same subjects had been able to accomplish; thus, while the prominent members of any society were responsible for the progress made, there was also a reflex action. Thus, "without Davy, Faraday, or Tyndall, the Royal Institution would never have become the important body it now is. But without the Royal Institution neither Davy nor Faraday would have had any opportunity for carrying out their scientific work, and of obtaining their scientific reputation, and perhaps the same may be said to a certain extent of Dr. Tyndall." In conclusion, Sir John Evans expressed his view that it was better for a society to do regular and consistent work than to be subject to a fitful energy, which would devise new ways instead of gradually improving the old. The meeting closed by a vote of thanks to the chairman for his address, which vote was proposed by Sir John Wolfe Barry and seconded by Sir Fredk. Bramwell.

New South Wales Electric Tramways.—We have received the report of the Railway Commissioners of the New South Wales Government on the railways and tramways in the colony for the year ended June 30, 1900. We are pleased to note that the electric tramways are being rapidly extended, and are meeting with every success. During the past year 43 steam cars in Sydney alone have been replaced by electric cars, and 133 new electric cars have been obtained for use on the various lines throughout the country. In Sydney particularly the electric cars and the regular service have greatly increased the traffic; on one line alone an average of 70,000 persons are carried each week-day (the route in question is between the railway station and the Circular Quay). These figures can be compared with interest with the traffic returns on the Central London Railway, which are not so very much greater. The return shows that the total number of passengers conveyed by the electric trams since the opening of the George and Harris street line on Dec. 8, and the conversion of the Dulwich-hill and St. Peter's line on April 2 last, was over 13,000,000. The result has been a certain amount of overcrowding in the early morning and in the evening. This overcrowding was prevented to a certain extent by running steam trams amongst the electric, but they were poorly patronised, the public preferring the inconvenience of the overcrowding rather than go on the steam cars. New lines are proposed to be constructed to avoid this overcrowding on routes in which the services cannot be increased, and the Commissioners urge that the construction of these lines should be pushed forward with all possible dispatch. On other lines also recently converted from steam to electric traction, and on which at the same time reductions in fares were made, satisfactory results have been obtained, but they are not always run at a profit. This is not likely to be the case in the first instance, but we are sure that the policy of the Commissioners is the correct one. It is more advantageous to the population that a large number should be served with good means of intercommunication at a cheap rate than that a small profit should be made out of a dear service to a few only. Since the running of the tramways by electric traction an unusually large number of street accidents have occurred, but the Commissioners add that in almost every instance these have been due to want of care on the part of the injured persons. This same result as regards accidents is to be found in every town directly after tramways are introduced, or have the speed and service increased, whether they are run by steam, electricity, or cable.

The St. Lawrence Power Scheme.—Special interest centres round the St. Lawrence Power Company's scheme, in that English engineers have been retained to advise the company on their electrical plant. We gather from the notices in the American Press that a number of technical papers were recently invited to send representatives to view the works as already constructed. From the reports of the various representatives we learn that good progress is being made, and that of the canal which is to convey the water of the St. Lawrence River to the Grasse River, the greater portion has been constructed. Thus, out of about 6,000,000 cubic yards of excavation, 4,500,000 have been removed, and it is thought that the canal will be ready for use next spring. The concrete work at the power-house is completed, and the building is roofed in; the turbines and generators are now being erected. It will be remembered that at the time when the company was first started, Messrs. Kincaid, Waller, and Manville, the consulting engineers in England, furnished us with the details of the plant to be supplied. These details have not been varied to any appreciable extent, but great care has been bestowed on the designing of the switchboard. With generating units of 5,000 h.p., the section of cables required for each generator of the size of the switch gear becomes somewhat excessive. To group all this switch gear together on the one switchboard would result in this board being too big to be conveniently operated. It would also be so large that the engineer in control could not readily grasp what was being done by the various machines in the station. To avoid this difficulty the switch gear for each individual machine is placed near it, and is controlled from a central spot by means of compressed air. The operator, then, has the various electrical instruments connected to each machine placed round in a conveniently small circle, so that they are all under his eye, and he can control the switch gear or regulating rheostat of any alternator much more easily than if he worked it direct. These pneumatic relays have been raised to great perfection by the Westinghouse Manufacturing Company, who are supplying the plant. It will be remembered that in this instance the civil engineering works are comparatively simple compared to what has had to be undertaken in other cases where large water power is available. About 75,000 h.p. will be the capacity of the present works, but they can be easily extended to give twice that output. Although the situation is one from which transmission is economically possible to a number of towns, the main object of the company is to supply power at such low rates as to induce new manufacturing establishments to be started in the near neighbourhood.

The "Lancet" Editorial.—We have elsewhere in this issue referred in terms of approbation to an editorial appearing in last week's *Lancet*, but we have now to express

Digitized by Google

our regret that the editor of an important and influential paper like the *Lancet* should write such utter rubbish as appeared in its editorial last week headed "The Dangers of Electric Light." That there are dangers from electric installations if wired in a bad way by irresponsible firms we should be the last to contradict, but still, if all the installations in London were carried out in this way, they would be better than those in an average Continental town, where electricity is still safer than any other illuminant. Even as the word "electricity" has been used by the daily Press as one to conjure with, even so it is now used where possible in notes of another character. For instance, electric tramcar accidents in which electricity plays no part whatever are being prominently advertised throughout the country, and one hears from untechnical people statements as to the danger of electric traction. If a man is killed in the London streets by a dray it finds no mention in the daily Press, but if a man falls off an electric tramcar electricity is blamed. To return to the editorial article in the *Lancet*; the writer displays a complete want of knowledge, as will be gathered from the following extracts: "It is common knowledge now that an otherwise innocent current—that is, one of low voltage—may through certain defects become an exceedingly dangerous current of enormous voltage. Earthing is, of course, the main source of trouble and the generally offered excuse, but if electric lighting is to be our mode of obtaining artificial light earthing must be overcome, and it seems to us that earthing has not been overcome—it is happening on all sides, and in several instances with most alarming results." The article then comments on a case in Regent-street, where in a photographic studio the electric current was said to be sufficient to light St. Pancras Station. The writer proceeds to compare this large current to a large reservoir of water, and concludes that there ought to be some means in restricting the quantity of electricity allowed on the premises. We suppose he knows what he means, but it is quite impossible to tell what this is from what is written. Reverting to the question of earthing, the article goes on to say: "In our own experience, earthing is constantly happening, and it is well known that in this manner a very high and dangerous current may be tapped by telephone wires, gas-pipes, or ordinary voltage electric cables." The climax is reached when the editor asks for Board of Trade regulations to be made and rigidly enforced, and for all cables and wires to be placed in separate tubes and return wires provided. One can only conclude that the editor thinks electric light installations in London are run on an earth return. He would perhaps be surprised to hear that most effective rules have been issued by practically all the fire insurance companies and by the Institution of Electrical Engineers. It is only the carelessness of the individuals using the electric light which prevent these rules being enforced. We repeat that we are exceedingly suprised that such an incompetent article should appear in the *Lancet*, and trust that its editor will see fit to apologise to the electrical profession for the misleading conclusions he has published.

Liquid Fuel.—At the ordinary meeting of the North-East Coast Institution of Engineers and Shipbuilders, Mr. E. L. Orde read a very interesting paper on "Liquid Fuel." In this he said that as new oilfields had been recently discovered and the cost of transit cheapened, it had become a serious question for shipowners to consider whether it would not be economical to use oil instead of coal on vessels trading towards the East. The solution of the question, he thought, lay, first, in the cost of the fuel and its practical calorific value as compared with coal; secondly, in its effect on the life of the boiler furnaces in which it was burnt; and thirdly, and perhaps the most important of all, its immunity from danger. The first point was, of course, constantly varying, and the other two practically resolved themselves into one—the efficient combustion of the fuel. The existing appliances designed for the purpose might be broadly divided into three—viz., those in which the liquid fuel was injected into the furnace in the form of a spray by purely mechanical means; those in which the spray was produced by the introduction of a gaseous medium; and where the liquid fuel was introduced into the furnace in the form of vapour. The experiments carried out by the author were made with crude Borneo oil, which was good fuel oil. The flash point of this oil was 211deg. F., and its calorific value 18,831 British thermal units. In the first type of apparatus for burning the oil, the mechanical spray, the oil was discharged under pressure into a burner, made so that the oil jet was broken up so as to burn readily at the firing point of the fuel. The advantages of this system were its simplicity and noiselessness. The best results with this type of apparatus showed an evaporative efficiency of about 12·5lb. of water per pound of fuel at 212deg. F. With the Borneo oil this gave a fuel efficiency of 64·6 per cent. In the second type, in which the oil is introduced into the furnace in the form of a spray in the presence of a gaseous medium, either steam or air, the best evaporative efficiency was between 13lb. and 14lb. of water from 1lb. of oil at 212deg. F. The third class, in which the liquid is introduced as a vapour, the author thought promised the best results, as an evaporation of from 15lb. to 16lb. at 212deg. F. should always be obtained with dry Borneo oil. The general conclusions produced from the investigations the author made were that liquid fuel of good quality, such, for instance, as Borneo oil, used in boiler furnaces, if efficiently treated, should show a reduction in consumption of about 40 per cent. as compared with coal; a reduction in bunker space of about 15 per cent. for the same weight of fuel could be made, and a reduction of about 50 per cent. for the same radius of action. There could also be a reduction in the stokehold staff of at least 50 per cent. The advantages of liquid fuel in case of manipulation, cleanliness, absence of smoke, reduced temperature of stokehold as compared with coal, increased life of boilers owing to constant temperature, improved performance of engines owing to constant steam pressure, were obvious, but the question of immunity from danger required some consideration. With a fuel oil of which the flash point is 200deg. F. or over there should be no risk of explosion whatever, and unless there is want of ordinary care in the management of the burning apparatus and the fuel supply, the danger of fire ought not to exist. Still, fires had occurred, and it might be well to consider the causes from which they had originated. The most fruitful cause appeared to be intermittent action of the burning apparatus. This might arise from dirt in the oil or from the presence of water. To get rid of the dirt it is only necessary to provide an efficient filtering apparatus, and this should form a part of all liquid fuel installations. The second cause, the presence of water, presented a more difficult problem. All crude oils had a certain proportion of water intimately mixed with them, and as the specific gravity of most fuel oils was from ·9 to ·98, and in the case of some shale oils even higher, it was obviously exceedingly difficult to eliminate this water by gravitation unless the temperature of the mixture was comparatively high. The expansion of oil under increase of temperature was considerably greater than that of water, and some arrangement whereby heat could be applied to the contents of the bunker seemed to be necessary where crude oil was used.

THE PHILOSOPHY OF DYNAMO DESIGN.

(Specially contributed.)

(Continued from page 736.)

It has been shown that by inserting an iron core into a solenoid the magnetic effect of the solenoid is very greatly increased, this being due to the fact that iron offers an easier path to the lines of force than air does; now the inductors lying in a slotted drum, surrounded on three sides by iron, and only separated on the fourth by a very short air-gap, the self-induction will be enormously increased, as the lines travel along a path of small reluctance. Fig. 23 shows the difference in the two paths for a slotted and smooth core, and it is self-evident that the self-induction effects would be still further increased if the armature be made of the perforated or tunnel type, which is sometimes adopted. We have seen that one of the fundamental principles is that $C = \frac{E}{R}$, and that this holds good in every case; and we have further seen that, owing to the very small amount of resistance which any individual armature coil has, a very low number of lines of force cut per unit time is sufficient to induce an E.M.F. which is of ample value to cause a large short-circuited current to flow round the coil. This E.M.F. may be produced either by the inductor cutting the forward lines of force, or from the effects of self-induction. If, however, the resistance of the coil were increased, there would be a great reduction in the value of the induced current, although the E.M.F. induced would be the same as previously was the case, and

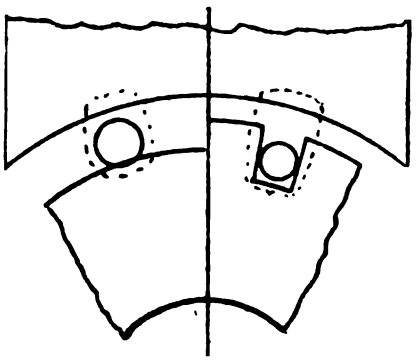

FIG. 23.

R would not require to be of very great dimensions before the value of the induced short-circuit current would be negligible.

The formula given previously, that $\frac{E \times 10^8 \times 60}{N \times C_a} = \phi$, may be written $E = \frac{\phi \times N \times C_a}{10^8 \times 60}$. Now if we assume that the self-induction is equivalent to each active length of a single complete coil inductor cutting 10,000,000 lines of force per second, and we substitute these values in the above equation, we shall get $\phi = 10{,}000{,}000$, $C_a = 2$, $N = 1$, or $E = \frac{2 \times 10^7}{10^8} = 0.2$ volt.

Mr. A. E. Wiener, in his "Dynamo-Electric Machines," gives an example of an armature wound with 84 complete coils and having a resistance of 0·0146 ohm. The resistance of each individual coil will be equal to $0.0146 \times 4 \div 84 = 0.0007$ ohm approximately. Inserting the two values $E = 0.2$ and $R = 0.0057$ in the equation, we get $C = \frac{0.2}{0.0007} = 285.7$ amperes. If an external resistance, say, equal to 0·05 ohm, were added in any way to the circuit, we should get $C = \frac{0.2}{0.0507} = 4$ amperes approximately.

Since the watts lost in the armature are equal to $C_a^2 R_a$, where C_a = the total armature current and R_a = the total armature resistance, it would not be advisable to increase the resistance of each coil to the amount stated above; for, taking the same example, and assuming that the current output is 300 amperes, we should have $R_a = 0.0507 \times 84 \div 4 = 1.0647$ and the watts lost 90,000 $\times$ 1·0647 = 95,823 = 129 h.p., in place of watts lost $90{,}000 \times 0.0146 = 1{,}314 = 1.89$ h.p.

It will be seen from Fig. 24 that the armature windings offer a completely closed circuit for the passage of a current, and that the current would only flow down to the commutator in order to pass to the external circuit, but that in order for a coil to be short-circuited on itself by the brush, the path of the current must be down lug *a*, through the corresponding commutator section, through the brush into the next commutator section, and thence along lug *b* into the coil proper again, and hence if the extra resistance of 0·05 ohm were placed anywhere in this external part of the circuit, the total resistance of the armature would only be increased by a very small amount. Now the question arises, where shall this extra resistance be placed? In the brush, either directly or by means of the brush contact; in the commutator sections; or in the lugs? It is often placed in the brush, which is done by utilising carbon in place of gauze brushes, but as the use of these opens up another issue, the adoption of this type will be treated separately. The commutator sections have been made of iron and other high-resistance metals, but the writer believes that the use of these metals for this purpose has now been entirely abandoned; any additional resistance placed in an electrical circuit will increase the heating effect at that point, and, as has been pointed

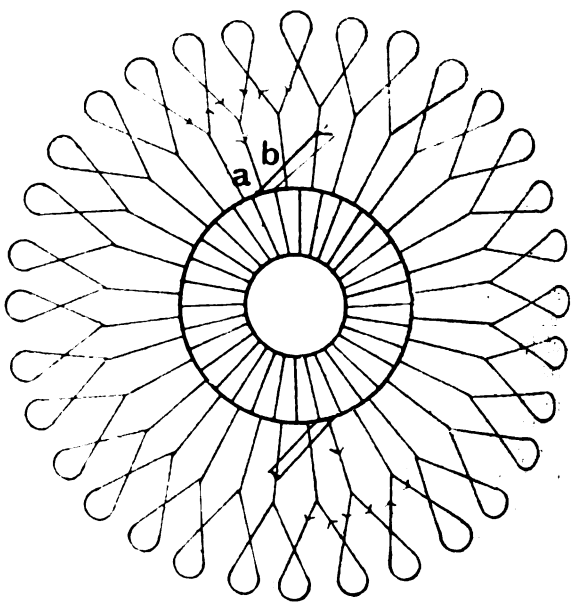

FIG. 24.

out when treating of the mechanical construction of the commutator, it is most inadvisable to do anything which will increase the heat of the commutator. The employment of reostene and other high-resistance metal strips has been suggested for the commutator lugs, and has given good results upon trial. If the lugs are made to have a resistance of 0·05 ohm each, the total increase in the resistance of the armature will be 0·05 ohm, because the current passes to the commutator at the positive brush, as we have seen, through two lugs which are in parallel to each other, and from the commutator to the armature through two lugs at the negative brush, which are also in parallel with each other, but are in series with the two positive lugs. The use of these lugs made of some high-resistance material will then largely damp the self-induction effects; and considering again Fig. 20, if owing to the increased resistance in the circuit of the *d* coil the short-circuited current has not risen to the normal of the *b* series—viz., 100 amperes—it will readily take the additional current required without sparking ensuing between Section 1 and the brush, because not only will there be an increase in the resistance of the path of the main *b* current, but also because the increased resistance of 0·1 ohm (because there are two lugs in the circuit of the *d* short-circuited current) in the *d* coil will prevent the self-induction from offering any great resistance to the growth of the current. Hence, as it will not now be necessary, in order to fulfil the requirements for

Digitized by Google

sparkless commutation, that the *d* coil shall carry exactly 100 amperes at the moment when it passes from under the influence of the brush, and is thrown into the *b* series; and there will be a certain amount of variation in the amount of current which can be sparklessly commutated with the brushes in one position, and a large amount of fixity of lead will be established. It may be necessary to warn the student that the inserting of high-resistance lugs may easily be carried too far, and that it should not be done to any great extent without the warranty of experience.

The substitution of carbon for gauze brushes adds to the resistance of the circuit of the short-circuited coils, not so much because of the increased resistance of the carbon brush as compared with that of a gauze brush, but owing to the imperfect contact of the brush and the commutator.

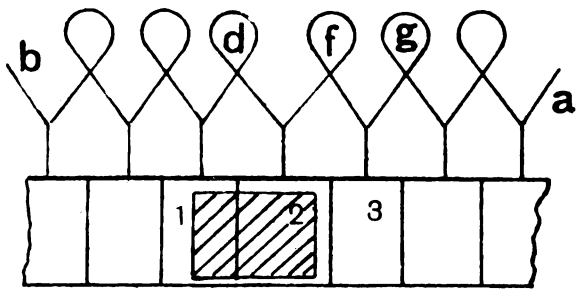

FIG. 25.

However well ground the contact area may be, the resistance of the contact area between copper and carbon is very great. That this has been found to be so in practice is evident from the fact that it has been found necessary to deposit a film of copper on the contact area of any carbon which forms part of any electrical circuit, such as the carbon plates used in batteries, and the faces of the carbon brushes which make contact with the brush-holder.

Now it has been already stated that if the path of a current bifurcates so as to give two parallel paths during part of its length, the current will flow down these paths in a ratio inversely proportionally to the resistances of the two paths, and it is evident that if the resistance of one path were gradually increased, while that of the other remained constant or even decreased, the flow of the current would gradually transfer itself from the path with the increasing resistance to that with the constant resistance, until when the resistance of the first path reached infinity, the current would have all been transferred to the other path. This is what practically occurs with the use of carbon brushes.

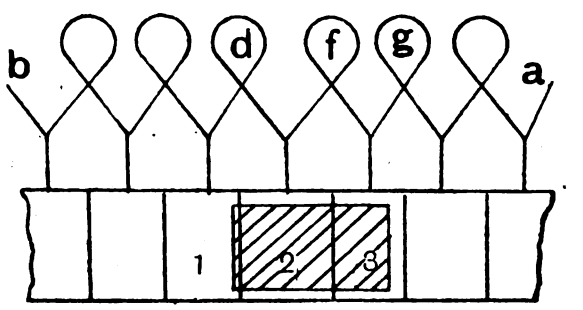

FIG. 26.

Considering again Fig. 20, the *b* main current, were self-induction eliminated, would flow to the brush through lug *w* and through coil *d* and lug *x* in amounts inversely proportional to the resistances of these two paths. Now we have shown that by the use of carbon brushes the self-induction is to a great extent eliminated, and therefore the *b* current may be considered as flowing freely through these two paths; and we have also stated that the resistance added by the use of carbon is not so much due to the specific resistance of the material as to the contact resistance of this substance and copper. Hence the resistance to the flow of any current from a copper plate to a carbon contact will vary inversely as the area of contact. If, then, we assume that the resistance of coil *d* (Fig. 25) to be negligible, the current from *b* will flow to the carbon brush equally through sections 1 and 2; but as the commutator revolves the brush will gradually cover less of section 1 and more of section 2, so that the resistance of the path through section 1 will increase and that through section 2 decrease, and the current will follow the path with the decreasing resistance, until when the condition of affairs shown in Fig. 26 is reached very little current will be flowing through section 1, and this will dwindle away to zero, as section 1 breaks contact with the brush, and there will be no current flowing either from the commutator to the brush or *vice versâ* to break, and hence there will be no sparking.

Although the self-induction has by the insertion of this high resistance been to a large extent overcome, it has not been entirely annihilated, and it will still oppose to a certain extent the increase of the main current through the coil, *d*, and will thus tend to increase the amount of current which flows through section 1, so that if we were to consider the carbon brush as built up of laminations insulated from each other, but making contact at the top of the brush, the current from section 1 would flow through the leading laminations, and that from section 2 through the trailing laminations; then the effect which this weakened self-induction would exercise would be to increase the current density in the leading laminations, and these would have a tendency to increase in temperature more than the trailing sections. This is the result which obtains actually in practice, and shows that the effects of self-induction have not all been removed by the employment of carbon brushes.

It has often been found that the substitution of carbon for gauze brushes has made all the difference between a

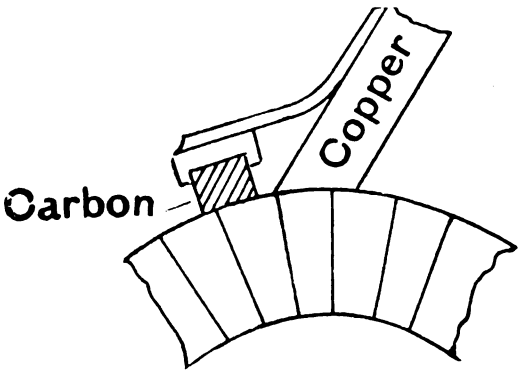

FIG. 27.

sparkless and non-sparkless commutation, but it is not always possible to make this substitution. The current density of the contact area for gauze brushes should be about 125 amperes per square inch, although anything up to 250 amperes per square inch may be permitted, but for carbon brushes the current density per square inch of contact area should be from 30 to 35 amperes, and should in no case be allowed to exceed 50 amperes, otherwise the brushes will get very hot, and the leading edge will soon begin to burn, so that it will be seen that considerably more length of brush line is required for carbon than for gauze brushes. With bipolar machines, this brush line can only be obtained by adding to the length of the commutator, which is a costly matter, but with multipolar machines, especially those for high E.M.F. and low current, the brushes being fixed at each pole, the length of the commutator is not unduly increased. When the length of the brush line is not sufficient to enable carbon brushes to be used, sparking may be sometimes cured by using a gauze brush having a carbon tip on the leading side. Fig. 27 shows one arrangement of this type where the carbon tip is carried by a thin spring copper or brass strip in front of the brush, and it will be readily seen that such a device will act to a great extent similarly to a carbon brush.

When carbon brushes are used, it is most imperative that the commutator be kept free from any superfluous oil or grease. If this is allowed to accumulate it will gradually collect under the soles of the brushes, where it forms a film of a more or less insulating nature, and so prevents the current from being properly collected, and arcing will take place from the commutator to the sides of the brushes,

Digitized by Google

and disastrous sparking, together with bad burning away of the commutator (which is positive to the brush), will ensue. If, however, the brushes are taken off in time, the commutator and the soles of the brushes cleaned, the sparking will disappear. It is also most important, in order to obtain the best results, that the soles of the brushes be properly cut to the curve of the commutator, and that before the machine is run with full load the brushes are properly bedded.

(To be continued.)

THE ARRANGEMENT OF THE DISTRIBUTING NETWORK.

BY CHAS A. GILLIN

The fact that the distributing networks of electricity supply stations do not receive that amount of attention which their circumstances and peculiarities would seem to claim has upon several occasions been referred to in papers and discussions by municipal electrical engineers and others interested in this particular branch of supply station practice; and although it is now receiving far more attention than was formerly the case, yet in many instances there appears to be a great want of system and foresight in the designing and arranging of these networks. This is especially noticeable at the commencement of supply, and the reason is probably not far to seek.

As a general rule, a clerk of works or a resident engineer is appointed to superintend the installation of the whole of the plant, its accessories, and the general equipment of the supply undertaking. This, of course, includes buildings, boilers, engines, generators, switchboards, and the distributing network, besides the usual business connected with the office work, etc.; and it can scarcely be expected that one man in every case can possess the intimate knowledge and experience necessary to lay out each of these essentially different branches of his profession so as to give the maximum amount of satisfaction and efficiency for all time, and the minimum amount of trouble in years to come. Of course, it will be said that this has all been arranged by a consulting engineer, but as a rule he designs only the *general arrangement* or the *scheme* of the undertaking, and merely specifies the majority of things in a general way (although there are consulting engineers who go thoroughly into the whole question).

In the case of the network, it frequently happens that the consulting engineer merely arranges for the distributing mains to be carried along a few of the principal thoroughfares, and arranges the feeding points, without any regard to the future, in places which suggest themselves to him after a few moments' thought as being convenient, and therefore the whole of the work of designing the network devolves upon the resident engineer. Thus when we find all the detail work, and, indeed, a large share of the heavier work, left to a man who has probably had very little experience in that direction, it need scarcely be a matter for astonishment when it is found years later that certain contingencies have arisen which have been unprovided for, but which would undoubtedly have been foreseen by a man experienced in this class of work; and that mistakes were made in expecting certain developments to take place which the man of experience would never have thought of expecting. It is in view of these facts that the writer will endeavour in the following pages to point out what he considers from experience to be the best method of arranging the network in the first instance, and in the system of extension afterwards.

It is not intended to enter into any of the advantages and disadvantages of any particular systems of distribution or to discuss their relative merits, nor is it necessary to enumerate and dwell upon the various conditions, depending upon the nature of the district to be supplied, under which certain systems of distribution are much preferable to others, information upon these points being readily obtainable from papers which have been recently read before the Municipal Electrical Association and other scientific bodies. We will confine ourselves exclusively then to the question of the *arrangement* and *design* of the distributing network, and to deal with the subject in a convenient manner we will consider it under the following heads, some of which are made compulsory by the Board of Trade rules and regulations, the remainder appealing to the engineer either from a purely business point of view or from the standpoint of good engineering practice: (1) uniformity of pressure; (2) maximum variation of pressure; (3) continuance of supply of electric energy; (4) facility in fault localisation.

1. *Uniformity of Pressure.*—The question of the uniformity of pressure is a very important one, not only on account of the Board of Trade regulations, but also from the business point of view, for the effect caused by the contrast produced by the fact of one consumer receiving current at several volts higher pressure than another in close proximity, is neither pleasing to the senses nor conducive to the extensive adoption of the electric light. Perhaps the most common cause of a difference in degree of light in adjacent premises is due to a want of balance in a three-wire system, thus causing an abnormal drop in the neutral wire, and a corresponding difference between the pressures on the positive and negative sides of the system.

Fig. 1 is a diagrammatic sketch illustrating a hypothetical case of this nature. F_+, F_0, and F_- represent the positive,

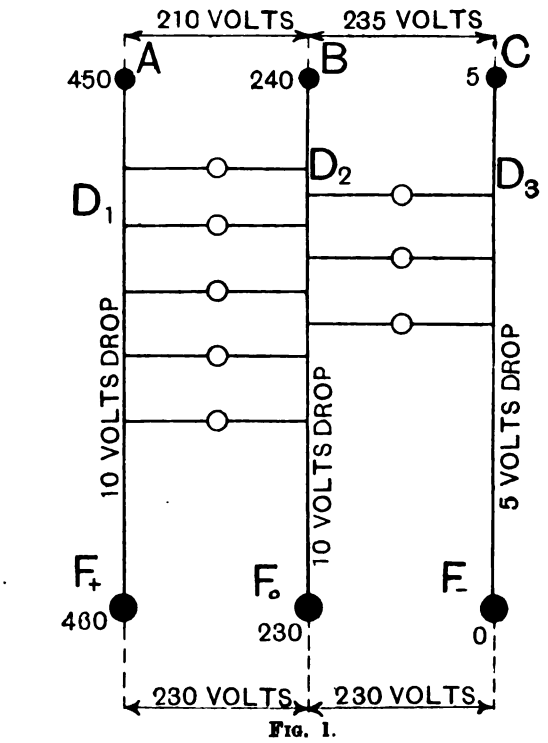

FIG. 1.

centre, and negative feeding boxes respectively, at any feeding point at which the voltage is maintained constant. A, B, C represent distributing boxes at some distance away from the feeding point, and it will be noticed that on the negative side the voltage across the distributors at B and C is higher than that at the negative feeding point. At first sight this appears somewhat paradoxical, but, referring to the sketch, we find that the total voltage across the two outers, A and C, is lower than the total voltage across F_+, F_- by the drop in pressure in the two outers, the drop in the neutral wire making the difference between the pressures across A, B and B, C. By studying the diagram (Fig. 1) the reason will appear obvious, as the voltage is marked at all points, and the drop in volts along the distributors, D_1, D_2, and D_3, is also shown. The only way to avoid want of balance is to observe great discretion in the connecting up of consumers by noticing particularly the probable time of demand and the nature of the load, and balancing consumers against one another in accordance with these observations.

The best method of effecting a good balance over the whole system and its integral parts may be explained by turning to Fig. 2, which illustrates diagrammatically the area of supply, each small square (as further explained in Section 2) representing a section of the network, each section being supplied with current by one feeder at or

Digitized by Google

near its centre—*i.e.*, the centre of the square. Consumers on the same side of each street in each section should be balanced against one another, and any difference in balance on one side of a street should be arranged to be compensated for by any opposing difference in balance on the other side of the same street or in one of the adjacent streets. It is important that the consumers on the same side of the street be balanced against each other, and not the consumers on one side against those on the other side, for by adopting the former method we obtain the minimum

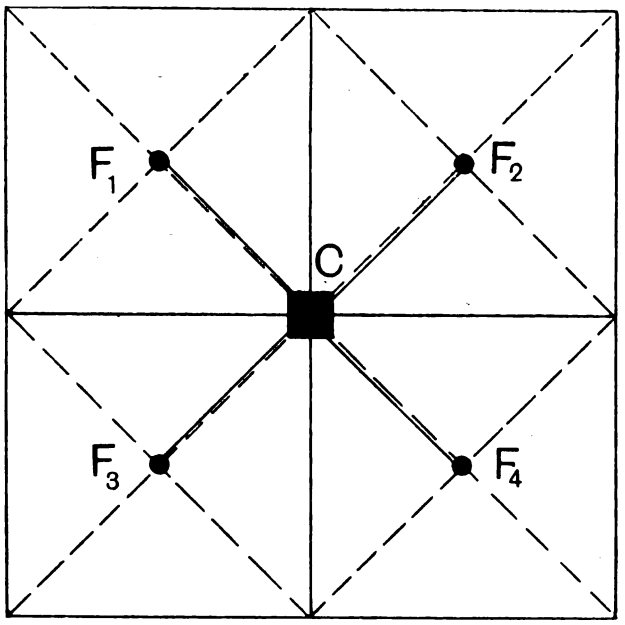

FIG. 2.

of drop of pressure in the distributors. The streets being thus balanced, the whole section containing these streets is, therefore, also well balanced, and, consequently, the load on each side of the feeder for that section should be nearly equalised, thus giving the minimum of drop of pressure on the whole system by the adoption of a systematic method of balancing consumers.

Another cause of a difference in degree of light in adjacent premises is found in towns supplied by a number of isolated networks, each of which networks is supplied by separate feeders; for although the pressure at each feeding point may be the same, yet there may be a great

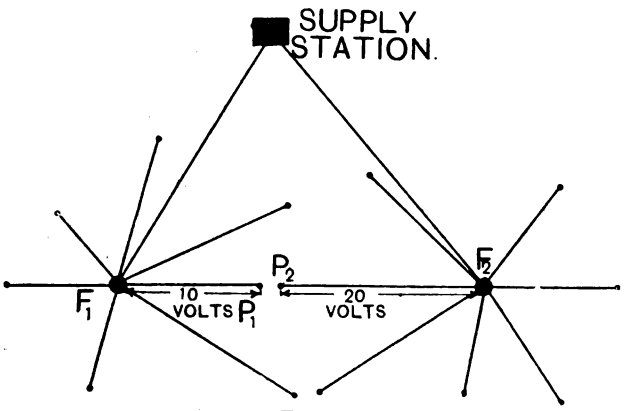

FIG. 3.

difference between the respective pressures at the contiguous ends of the various networks. This will be seen by reference to Fig. 3, where the pressure at the two feeding points, F_1 and F_2, is shown to be the same, but the drop in volts along the distributor, $F_1 P_1$, is greater than the drop in the distributor, $F_2 P_2$, owing to a difference in the amount of current carried by each of these cables, whose sectional areas are equal. The remedy for this state of affairs is purely one of design, and consists of a judicious interconnection of the various distributors of each network, combined with an exercise of judgment with regard to the terminations of the cables of each network relative to the terminations of the cables of the other networks.

2. *Maximum Variation of Pressure.*—This section should have been treated under the heading of "Uniformity of Pressure," but it was thought advisable to treat it separately, as it involves factors which do not really come under that heading.

The maximum variation of pressure in any network, according to the Board of Trade regulations, must not exceed 3 per cent. ($2\frac{1}{2}$ per cent. in high-tension systems) of the declared pressure—*i.e.*, the pressure which the supply company or corporation declares to be that at which the current is supplied to the consumers connected to the network. Complaints very often come to hand from various consumers, who state that shops or houses in one part of the town are better lighted than their own premises which are situated in a different quarter of the town, and it is therefore incumbent upon the undertakers to keep the percentage variation of pressure as low as is compatible with economy, and by so doing to give complete satisfaction to everybody as far as possible.

One of the questions to which we must give our attention at the commencement of supply is, therefore, how to so design the arrangement of the network as to keep within the Board of Trade limit of variation, not only at the present time, but also at any future time when it may be necessary to make extensions to various parts of the town and its environs. In dealing with this point, a knowledge of the district with which we are concerned is really necessary, but the general method of procedure may be set down in such a manner as to meet the requirements of any ordinary town. Variation of pressure depends upon drop in volts, and drop in volts depends upon three principal items—viz., the length of the conductor, the sectional area of the conductor, and the amount of current carried by the conductor. Of these three items, it will be comparatively simple for a man experienced in this work to very soon estimate one of them—the amount of current to be carried. Having obtained this, we are in a position to find the sectional area of the conductor required, for the question of safety precludes us from loading the cables above a certain density per square inch of section, say 500 or 600 amperes. But there is another factor to consider in this connection—viz., the most economical section of conductor, compatible with safety, to use. The results of the investigations of Lord Kelvin, Profs. Ayrton and Perry, Mr. Kilgour, etc., into matters relating to the sizes of feeders and distributors, have been exhaustively treated upon by the authors themselves in the technical journals, in their own publications, and in papers read before scientific associations.

The formulæ deduced by them cannot, however, be used without some definite data to work upon; and in the case of new supply undertakings it would be wise to take the sizes of their cables from those adopted by other undertakings, working in similar places, and under similar conditions, until they are in a position to supply their own data, when they can, before the works assume very large proportions, reorganise their network to suit their own cases. Assuming that the above-mentioned data are available, the most economical section of conductor to employ can be calculated by methods for the explanation and elucidation of which the reader is referred to the publications mentioned above, and especially to Mr. Kilgour's contribution on this subject in "Practical Electrical Engineering," as it is impossible in the space available here to do justice to the subject, and any abridgement of it would only be confusing without serving its purpose.

It is advisable to carefully study the area of supply and its probable extensions, and if the necessary data be available, to make the required calculations which, aided by experience, will enable several standard sizes to be adopted for the cables for the distribution of the current. These standard sizes should then be adopted throughout the system. The sizes of distributors vary, as a rule, between ·3 square inch and ·04 square inch. That portion of the area of supply which may be designated by the name of city or town, as distinguished from the outlying districts, can now be divided into squares, of which half the length of the diagonal is such that the drop in pressure in an equivalent length of the predetermined size of cable, at what is estimated to be the maximum current which will flow through any one

Digitized by Google

of the distributors, at the working pressure, is slightly lower than the variation of pressure allowed by the Board of Trade. The diagram shown in Fig. 2 represents this portion of the area of supply of any town or district into which a system of distribution of electric energy is to be introduced. C indicates a point situated at the centre of this portion of the area, and straight lines intersecting each other at right angles are drawn through it. The maximum length of the distributors from any feeding point—*i.e.*, half the length of the diagonals of the squares—as obtained above, is marked off from the centre, C, along each of these lines, giving the points F_1, F_2, F_3, and F_4 as the centres of the squares. The most convenient places near these points will then be our prospective feeding points.

The sizes of the feeders, as in the case of the sizes of the distributors, are perhaps more a matter for the dictates of experience than for the results of calculations, although having already agreed upon the sizes of the latter, we are in a better position for the determination of the sizes of the former, except in so far as the drop in pressure and economical working is concerned, for in the former respect the length of the proposed feeder will obviously have a great bearing on its section, especially when no device is used at the supply station for maintaining the standard voltage at *each* feeding point. Any such device, however, is quite unnecessary in the majority of well-designed networks, and their employment should be rigorously avoided, unless absolutely essential to the proper maintenance of the correct voltage, as it is unwise to complicate the switching arrangements at the supply station more than necessary. In some instances, as, for example, when the supply station itself is used as a feeding point, a regulating device for adjusting the voltage at the feeding point is absolutely necessary, the section of the feeder being then determined only by the amount of current it has to economically transmit. It will undoubtedly become advisable at some future time to extend the cables into the outlying districts, and when this becomes imperative, each of these districts can be treated in the same manner as was the more important central area of the town in the first instance; a sub-station, fed from the main supply station, being employed to receive current at high pressure, which would here be transformed down to current at low pressure for distribution among the consumers in the district.

The sub-station might be used as a distributing centre if more than one feeding point should be found to be necessary, or a sub-station and transformers could be placed at each feeding point if circumstances involving economical factors, such as distance, etc., rendered it expedient to adopt such a course.

It will be seen that in any distributing system arranged on the lines indicated above, extensions may be made in all directions without very much danger of large variations in pressure occurring at different parts of a town and its environs.

(*To be continued.*)

RELATIVE ADVANTAGES OF DIRECT-CURRENT AND THREE-PHASE DISTRIBUTION FOR SMALL INSTALLATIONS.*

BY H. A. EARLE.

When accepting an invitation to read a paper before this Institution I was for some time in doubt as to what subject I should choose; none was particularly uppermost in my mind as one upon which I wished to discourse, but I came to a decision while travelling abroad; the question covered by the title of my paper being brought most prominently before me, owing to the competition and different statements I met with, with regard to the relative advantages of three-phase and direct-current machinery for small and medium sized installations. Owing to this it occurred to me that a comparison between the two systems would be of interest and likely to give rise during its discussion to points which would be a guide for the future. Competition is not always, especially in some countries, carried on on strictly commercial lines, and I have experienced instances where a competing firm, finding it could not secure an order for direct-current machinery, has offered polyphase machinery as an alternative, singing its praises at great length, setting forth advantages without number, and naturally ignoring the other side of the question; this is not as it should be, but with inexperienced purchasers, with no one to guide them, it is at times successful.

I have found the title I first adopted for my paper somewhat too limited in its scope, and have briefly considered questions which relate to the distribution from sub-stations, as well as that of the choice of machinery and distribution for small installations. The type of machinery, and the system to be adopted for supply and distribution, are in the case of large plants most carefully considered, simplicity of design, first cost, and subsequently economy being among the most important of the many factors. In the case of small installations, however, such as are put down to supply light and power for mills and factories, the question is not infrequently decided irrespective of theoretical considerations. The purchaser in England is very usually in the hands of the consulting engineer, but in countries where this commodity does not exist he is often guided by the persuasive power of the seller, and sometimes by fashion. For the lowest price may mean but little as regards cheapness when there is no specification. There are many ways of preparing a low tender, and the omission of something in one which is included in another, the adoption of different voltages, various groupings of lamps and motors, different speeds for generators and motors, may give one system an apparent advantage over another which it does not in reality possess.

Many firms have, up to the present, given their chief attention to direct-current work, and this has met the wants of the smaller installations as well as those of the greater portion of the large central stations. Single-phase supply at high voltage, with distribution from transformer stations, has competed keenly with direct current, but lamps of higher voltage, together with three-wire distribution, has given the latter a long lease of life, and has enabled it to be employed for large areas without undue loss or a prohibitive cost of copper. We have seen 50-volt and subsequently 100-volt lamps in regular use for large installations, but now 200 up to 230 volt lamps are quite the accepted standard, and this higher pressure has so largely reduced the first cost of copper that in many stations where the use of alternating currents was formerly warranted, direct-current machinery is being put down, and even in some instances the alternating-current machinery being taken out. Running and driven balancers, together with feeder boosters, are required as auxiliary machines for direct-current three-wire distribution, from sub-stations dealing with large powers, and feeding over a considerable area; but it is more than probable that in the future 400-volt lamps will be available, which, with a two-wire distribution, would render the two first-named machines unnecessary, and eliminate the cost of the centre wire. As polyphase and monophase machinery live on the price of copper, it can be fairly assumed that every saving in this respect will take away their livelihood and reduce their utility. Where lighting constitutes the largest proportion of the load, the copper required is proportional to the watts per candle taken by the incandescent lamps; any reduction, therefore, in this respect is of great importance. Lamps are, I understand, shortly to be put on the market consuming two watts per candle, or even less, and every advance in this direction is, I again hold, to the advantage of direct current, and will enable it to cover a wider field, for who will use high voltages and transform down if they can use low with equal economy, or include complications when they may be omitted? All auxiliary machinery and apparatus has only one object, and that is, to reduce the price of the mains, or, as I have seen it stated, adopted in the vain endeavour to cheat Ohm's law out of its due tribute of copper. There are some who blindly champion alternating and polyphase systems, call commutators excrescences, and quote experiments, which claim to show that polyphase weigh a mere fraction of direct-current machines. A statement in Herr von Dobrowolsky's remarks in the discussion on a paper read by Herr Görges in 1892, was quoted in the first

* Paper read before the Manchester Section of the Institution of Electrical Engineers.

Digitized by Google

edition of a book, and has again appeared in the second edition—namely, that a certain multipolar continuous-current machine gave 11,000 watts, but that when a three-phase armature was run in the same fields, it gave an output of 33,000 watts. I doubt this test being one which one could consider upon a commercial basis. On turning, however, to the paper in question, I find that Herr von Dobrowolsky also said: "An alternating-current machine is so totally different in its construction to a direct-current machine, that such comparisons cannot be fairly made, and that it is equivalent to saying that a spoon has an efficiency of 100 per cent. when used for soup, but only one of 50 per cent. when used for cutting." Notwithstanding all this the polyphase system is at the present time the most satisfactory solution of long-distance transmission, and will be utilised more and more to transmit large powers into the centre of towns, and to cope with the many difficulties which present themselves, but the chief point I desire to raise is, whether the distribution from the sub-stations should be by polyphase or direct current, and whether for smaller installations one system offers such advantages over the other as to warrant a preference being given. Notwithstanding the existence of several eminent advocates of single-phase machinery I do not propose to consider it, nor have I had to deal with it in connection with the competition I have experienced, especially abroad.

With regard to the two remaining rival systems, the commutator seems to be the red rag of polyphase exponents, but any trouble that has been experienced on this behalf is merely a passing nightmare, and has only occurred with machines of large power running at high speeds, in connection with which considerable experience is required and very high-class workmanship demanded in order to enable carbon brushes to maintain good contact on a surface running sometimes as high as 40 miles an hour. This difficulty has been experienced by most of us, but is being rapidly overcome, and in a short period it will be a thing of the past; it is, however, much to be desired that the high engine speeds which have been saddled upon us for plants of 1,000 h.p. and upwards, may in the future be reduced some 20 per cent. With reference to the comparative weights of direct-current and polyphase generators, we may take as a good example of the latter one of the 32-pole three-phase generators built for the Central London Railway, and which has an output on full load of 850 kw. at 94 revolutions; this machine has a weight of 37 tons, or with exciter, say, 39 tons. As an example of a large direct-current traction and lighting generator, we may take one of a number of 10-pole machines, now being built at Salford Ironworks, having an output of 900 kw. with fixed load, and running at 95 revolutions per minute. This machine has a weight of 45 tons, or correcting for the increased output, it equals 42 tons; this machine could, however, have been built lighter as a shunt generator, with the compound windings omitted, and with the smaller range of voltage than necessary, the magnets would have been lighter, and probably with advantage more in number; the weight would then have been practically identical with the polyphase generator, with which it has been compared. With regard to the weights and prices of still larger generators, I have compared a 1,400-kw. $\times \cos \phi$ polyphase generator running at 93 revolutions with a direct-current one of the same output, and for the same speed; the former with exciter would weigh approximately some 64 tons and the direct-current generator approximately the same. Comparing the prices of the above machines, the polyphase has the advantage, and is approximately some 12 per cent. cheaper to build, this being chiefly due to the cost of the commutator on the direct-current machine. There is, however, one point which cannot be passed by unnoticed, and that is the small safety clause attached to the output of the polyphase machine—namely, cosine ϕ. What is this? Why, it means that on an inductive load this apparent 12 per cent. advantage is wiped out, and may even, and very probably will, put the boot on the other foot; but more of this later on. With regard to smaller sizes of 200 kw. to 400 kw. I do not find that there is much difference—in fact, the figures I have tend to show that the advantage is on the side of direct current; but I will not press this point. Respecting the weights of the two types of motors, the polyphase type with squirrel-cage rotor is considerably lighter, but the large motors of 50 h.p. to 100 h.p. with wound rotors weigh about the same. Comparing the price at which the smaller sizes are sold, the polyphase have an advantage of about 5 per cent.; but figures I have carefully examined for motors from 10 h.p. to 100 h.p. with wound rotors show a good average of 10 per cent. in favour of continuous-current when compared with polyphase motors imported into this country, and the cost of importation does not amount to 10 per cent.

Considering next the cost or weight of mains, the advantage is on the side of three-wire direct-current distribution, as may be seen from Table A, in which it is assumed that the various systems are for incandescent lighting as well as for power, and that the voltage is limited by the lamps, the circuits being so arranged that each lamp can be switched on singly. As regards the voltage, column 1 gives the virtual volts between any two wires when lamps of the same pressure—namely, 200 volts—are employed on each system, but this figure may certainly be taken exception to in the case of the alternating systems, for it must not be forgotten that their maximum voltage is the $\sqrt{2}$ times their working voltage, or 1·41 times as great. And this cannot be lost sight of when taking into consideration the questions of insulation and risk from shocks. I have accordingly given in column 2 the maximum voltage between any two mains on this basis. There is also another point to be borne in mind in connection with the mains for polyphase systems which contain many motors, and that is for equal loss they must be increased in section at least 10 per cent. above that given in the table, and required for continuous-current systems, in order to allow for the loss due to wattless currents, and this figure may have to be still further increased to 20 per cent., or even more should many of the motors be put down to deal with very variable loads; in fact, the section of the mains in the table must be increased in the inverse ratio of the power factor of the system, taking into consideration both motors and lamps. In the comparison, a third or common wire has been included, where necessary, to fulfil the condition of individual control, but the systems are assumed to be in balance—*i.e.*, there is no loss in the centre wire, which has been taken in all cases as 25 per cent. of the weight of an outer. It is seen that continuous-current three-wire systems are only beaten by one—namely, in the case of the three-phase star with common return, but then the saving by having only three wires instead of four to fix and insulate would cancel this small difference, not to mention the better regulation which can be obtained with continuous-current machinery. With regard to this small difference of one, the three-phase star has, moreover, no right to, for it is entirely eliminated, and the tables are turned, by what I have said respecting the loss due to wattless currents when motors are used; and the three-wire direct-current system is then found to be at least 10 per cent. the best of all, as regards the weight of copper. From the way I have drawn the diagrams of the three-phase star circuits, it can readily be seen why, when lamps are used, the fourth or common wire is necessary to maintain proper regulation of voltage on the lamps, for without it the system would be comparable to a continuous-current two-wire system with three lamps in series.

Turning next to the question of running motors upon the circuits, the points to be considered are: (1) starting torque; (2) regulation of speed; (3) constancy of speed; (4) efficiency. Polyphase motors are essentially constant-speed machines, and the speed of the smaller sizes is high, the arrangement of the winding is limited, and in this respect they do not so readily lend themselves as continuous-current motors do to windings by which any desired speed can be obtained. Various ingenious methods have been adopted to meet the requirements, which are more or less satisfactory, but there is still considerable room for further development.

1. *Starting Torque.*—A continuous-current motor even when shunt wound exerts its full torque, with a small increase of current over the full-load current, and is capable of satisfactorily dealing with any work for which it may

be employed. Small three-phase motors with squirrel-cage rotors, starting with full torque, require a momentary rush of current, approximately equal to 2½ times the full load current. This is an undesirable feature, and to obviate it motors of larger powers are started up with a resistance in the rotor circuit. This minimises but does not remove this defect. This behaviour would prevent a three-phase power installation being arranged so that all motors may start up with the generator. With respect to this, I arranged a power installation of 850 e.h.p. in a large spinning and weaving mill abroad, in which are included some 10 compound-wound continuous-current motors, placed long distances apart, and ranging from 220 h.p. to 230 h.p. In this installation all the motors can start up simultaneously with the generator on practically full load the starting current required being not more than some 50 per cent. in excess of the full working current. In cases where the running torque is constant, but where a great starting torque is required, series-wound continuous-current motors offer the best solution. I have one case especially in my mind, in connection with a polyphase installation in a cotton mill, where a large number of motors of 8 b.h.p., with squirrel-cage rotors, were put down, each to run a line shaft driving 24 narrow looms. In this case trouble was experienced in starting up, belts coming off, or the motors, especially on Monday morning, when everything was stiff, refusing to start at all. Larger motors were in some instances put in, and in others fast and loose pulleys were added: a 7-h.p. direct-current motor would have done the same work, and have given better results. One method of increasing the torque of polyphase motors on starting is to increase the voltage on the stator by means of a booster transformer. Another method is to alter the connections of the stator windings from star to mesh, this increasing the pressure in the ratio of 1·73 : 1. Another arrangement is to change the connections of the stator coils from series to two sets in parallel. The requisite starting torque can, however, be obtained from a direct-current motor, whether shunt or series wound, without any of these devices.

2. *Speed Regulation.*—The regulation of speed, either of continuous current or of polyphase induction motors, is effected by somewhat similar means. The speed of an ordinary shunt motor can be varied in three ways, either by inserting a resistance in the armature circuit, by altering the voltage of supply, or by varying the strength of the fields. Like shunt or series direct-current motors, polyphase motors, except the smallest sizes, require a resistance to be inserted in the rotor or revolving windings to keep the starting current within bounds; merely by the use of such a resistance any desired variation of speed can be obtained with either type. With this method of regulation, however, the input remains practically constant, and it is, therefore, too wasteful to be adopted where a high average efficiency is imperative throughout the whole range of speeds. A direct-current motor running on a three-wire system with two voltages available, combined with regulation of the field, can be made to yield a very high mean efficiency equalling 83 per cent. for the whole of the working range—that is, for some 66 per cent. of the speeds and an average of 75 per cent. throughout the whole range. Weakening the field by introducing resistance into the stator circuit of a polyphase motor increases the slip and the motor runs slower, but as the field supplies the rotor current in the same manner as the primary of a transformer supplies the secondary, the torque falls off very rapidly. By doubling the number of poles in the stator winding the speed can be halved; this necessitates, however, an inconvenient number of windings, increases the complication of the switch, etc., and is rather impracticable. Considering the various devices as a whole, one cannot but be drawn to the conclusion that the direct-current motor on a three-wire system, with two voltages available, or on a two-wire system with double-wound armature, together with the provision for some field regulation, is the simplest and most desirable, for it gives all variations of speed most economically, and it can be easily arranged so that there is no jump whatever between one speed and another. Three or four instances have come to my notice where power has been transmitted to a works from a considerable distance by polyphase current, but in connection with which

Digitized by Google

motor-generators have been added to supply direct current to motors requiring to be operated through a large range of speed at a high mean efficiency.

3. *Constancy of Speed under Varying Loads.*—In this respect a shunt-wound continuous-current motor acknowledges no superiority to the polyphase: the slip on the latter increases with the load, but shunt-wound motors are available which can maintain constant speed from no load to full load. For tramway work a polyphase motor will maintain a more constant speed when climbing hills than a series-wound continuous-current motor, but as this is at the expense of current, a high speed on the level and a slower speed on hills seems more to be desired, and likely to reduce the maximum current demanded from the station.

4. *Efficiency.*—I have compared the efficiencies of direct-current motors, which have been most accurately tested, with figures which I consider are fairly representative of what can be obtained with polyphase, and give the comparisons below:

B.H.P.	3½	6	10	25	50	100
Direct-current ...	82%	85%	86%	91%	92%	92%
Polyphase	75%	80%	84%	88%	90%	91%

This shows a large superiority for direct-current motors of small power, and a small advantage on the larger sizes. The power factor of polyphase motors, as far as any published figures go, as well as those which are obtained from various makers, vary more widely than seems at all necessary, and in order to obtain a fair average I dotted all the power factors I could get upon a sheet of paper, and then drew a curve through the lot, and I give you below the readings which resulted from this curve. Power factor for polyphase motors on full load:

B.H.P.	5	10	15	25	50	100
	·76	·79	·81	·83	·86	·88

With regard to the above, it is needless to remark that the power factor of continuous-current motors is unity. Having considered how the various operations are effected for changing either the speed or torque, or both, let us consider the conditions under which motors have to work. These may be divided under four heads, and stated as follows: (1) constant speed with constant torque; (2) constant speed with variable torque; (3) variable speed with constant torque; (4) variable speed with variable torque.

Constant Speed with Constant Torque.—This condition is one which exists when motors are used to drive lengths of shafting, from which again are driven a considerable number of small machines, such as are found in a cotton mill or a large machine shop. In this instance the load is fairly constant, possibly not varying more than some 10 per cent. It is in such cases that a polyphase motor is at its best, and endeavours to rival the shunt-wound direct-current motor, which, however, is just as good for the purpose, or probably a little better.

Constant Speed with Variable Torque.—This second condition occurs in cases where large portions of the load are being frequently thrown on and off; the shunt-wound motor is all that can be desired as regards speed on such work, and the current taken is in fair proportion to the load. The polyphase motor is also satisfactory as regards speed, but the current is high on the lighter loads; a considerable percentage is certainly wattless current, but it adds up the $C^2 R$ losses, and at the same time decreases the capability of the generator for useful work; and this is a point which must be borne in mind when comparing a polyphase generator with a direct-current one. We have seen how a power factor less than unity for the motors necessitates an increase in the size of the mains, and this acts in a similar manner upon the generator. If the current were in phase with the E.M.F.—that is, if the power factor were 1, in place of averaging, say, ·85—the polyphase generator could do 17½ per cent. more work than it would be able to do under the latter condition. But, again, with many motors working on a system, a power factor of ·85 cannot always be relied upon, and one of ·75 or even lower may have to be reckoned with. We see from this that the first cost of an installation may be considerably increased by this consideration, and besides this the wattless currents exercise a very bad effect on the regulation of a three-phase machine, very much more so than if the currents were in phase, necessitating very much heavier windings on the magnets to deal with a low power factor than a high one.

Variable Speed with Constant Torque.—This third condition is met with very frequently—for instance, when driving callenders, paper-making machinery, and in pumping, etc. To meet it with polyphase motors the regulating switches are more complicated, and to effect many changes of speed the groupings of the winding become many in number, and efficiency is sacrificed. In this respect the continuous-current motor is more easily managed, and will yield a higher mean efficiency.

Variable Speed with Variable Torque.—The fourth condition is especially present when driving calico printing machinery. An eight-colour machine, for instance, may be utilised for printing any desired number of the eight colours, the torque increasing practically in direct proportion to the number of rollers in use. The speed of printing the goods at the same time varies in accordance with the number of colours being printed, and with the class of work the machine is doing. For this class of work a very even turning moment is necessary; one must be able to run up to any desired speed without jumps or jerks, and the contemplation of a three-phase motor arranged for high efficiency at all speeds and to comply with the requisite conditions, is not a taking one.

I have heard the point raised that for factories where there is much inflammable dust about, a chance spark from the commutator might set the place on fire, but perfectly satisfactory entirely enclosed direct-current motors are at work, not considering the thousands on tramcars, but also in factories of all descriptions; fireproof gauze covers are also employed for motors—these do not exclude all ventilation, and render the motor quite reliable even where spirit vapours are present. The facility for the use of batteries on direct-current systems is one which must receive careful consideration. These are continually improving in quality, give excellent results in the hands of those that understand them, and offer great advantages, both as a stand-by and as regulators; they can therefore frequently be utilised to assist direct-current supply, and at times to effect considerable economy, whereas a three-phase battery has yet to be invented. Polyphase motors appear specially suitable for long lines of railway where considerable distances are travelled without a stop at a uniform rate of speed, and where crossing-points which would complicate the conductors do not exist, for beyond a comparatively limited distance high voltage must be used, and then, whichever system is employed, transforming apparatus is necessary; in such instances polyphase supply, with polyphase motors on the train, would not call for rotating transformers, stationary transformers along the line being the simplest and cheapest arrangement. Such a system is, however, unsuitable for use in towns with frequent stops and a very variable rate of speed; besides this, I am sure that it would create a great commotion among the inhabitants of a town not 100 miles away if it were proposed to erect two trolley wires in place of the one, which to some already appears distasteful. Judging from what some of the larger firms on the Continent are doing with respect to polyphase machinery, I understand that, although they have given it the very greatest attention, they find that the volume of their direct-current work exceeds that of the polyphase.

I have endeavoured to consider the chief points which should guide us in the choice of a system for use for the smaller installations. In cases where lighting alone is required, the first cost of polyphase or direct current would appear to be very similar; the simplicity of the latter system, both as regards the wiring and the regulation of the voltage to my mind, gives direct current the preference. Where a number of motors are on the circuit for whatever purpose they may be required, and whether the system includes lighting or not, I consider that direct current shows a very decided advantage, except in a few very special cases. Moreover, the use of batteries is all but excluded with polyphase systems, even for a night load, and this is frequently of considerable importance. I have, doubtless, to some minds,

Digitized by Google

left unsaid many things I ought to have said, and to others said many things I ought not to have said, but this may be more an advantage than otherwise, for it will admit of those shortcomings being criticised during the discussion, and may enable me to fill the gaps and correct my errors.

Discussion.

About 120 members and friends attended the meeting at which the above paper was read. Dr. Edward Hopkinson took the chair. The discussion was very much interrupted by the hissing of an arc lamp, and the **Chairman** said although he believed in continuous current for arc lighting, he did not think he could take the present lamp as an ideal example of good work.

During the reading of his paper **Mr. Earle** said that he had recently found that from 25 to 30 per cent. more power was required to start up shafting on a Monday morning than was required on any other morning.

Mr. Miller, who opened the discussion, said that he would have preferred to have spoken later on in the evening. He, however, generally agreed that for small installations direct current was the proper thing, especially for motors, as the speed could so easily be varied. He gave an instance of a shipyard that had come under his notice where in one or two yards polyphase distribution was employed which worked very well, while in the other yard continuous current was employed, which, in his opinion, worked much better. He also gave another instance, in which the Helios Company had been asked for their opinion as to which was the better plant to instal where a pressure of 230 volts was required, and they had replied that for this pressure and particular job three-phase distribution could not be recommended, as it was only of use in cases of long-distance transmission. Mr. Miller went on to say that many installations of polyphase distribution had been put in merely on the recommendation of the seller, and that there were many people in this country holding the idea that nothing was good in the way of electrical machinery unless it came from the Continent or America. He had lately been reading Mr. Fedden's report to the Sheffield Committee, and he took it that the report was mostly in favour of single-phase distribution. As to three-wire distribution for small installations, he did not think it was necessary, as it involved complications, and small installations should be kept as simple as possible, so as to secure good work being put in. In America polyphase transmission was much used, but not for ultimate distribution. On the larger question of town lighting, no offhand statement could be made as to whether polyphase or direct current was the best to use, as each case must be considered on its own merits.

Mr. Sayers congratulated Mr. Earle on his paper, which he had read with interest. He considered that they could not attach too much importance to the question of speed regulation, and it was not always easy to make a case out for electricity when considering the question of steam-engine *versus* electricity for driving machines, as the question of convenience and facility for turning out work depended on speed. He thought it would pay generally to put in motors with variable shunt resistances where variable-speed motors were used, and if a machine will commutate properly, it would maintain its speed fairly evenly with a variable torque.

Mr. Wood said he had no doubt that continuous-current semi-enclosed type motors were the best. He had known of a case, on a combined motor and lighting installation, where alternating current was used, and when switching on the motors the voltage was reduced from 110 to 70. He had, however, found no difficulty in starting up an installation of three-phase motors, if all the motor switches were first closed, and then the generator started up with a strong field. He thought that three-phase motors would be more advantageous on the question of price when compared with dust-proof continuous-current motors, and that such motors could be advantageously used in coalmines and very dusty places generally. On the Continent he had seen three-phase motors in use with cone pulleys so as to get variable speed.

Mr. Lacey said that Mr. Earle's paper had put all the points in favour of direct current, and that he agreed with him where variation of speed was necessary. He had known of a case in a printing works where it was desired to regulate the speed of motors from the foreman's box, without the actual user knowing anything of it, and he thought it would be difficult to do this with polyphase motors. For tram work direct current was much more advantageous. He had only seen Mr. Earle's paper just as he had come into the meeting, and would have liked to have had time to study it at leisure.

Mr. Lindley said he thought that a polyphase motor was mechanically perfect, and that the absence of a commutator was a very great benefit. Change of speed he knew was a great question, especially for machine tools, but it was surely not hopeless to expect that something could be done in this matter with polyphase currents. As to engine speeds, he thought that in the long run the higher speeds must win.

Mr. Richardson said that there was probably no greater advocate for three-phase currents than himself, but he thought there was no surer way of killing the system than by indiscriminate recommendation. No doubt central-station engineers would be very pleased to see 400-volt lamps on the market. He could not agree with Mr. Miller as to the use of three wires, as he thought that the complications were of very small moment where two voltages were available. At the Niagara station, out of 40,000 h.p. he had found that 14,000 h.p. was actually used as continuous current against 8,000 h.p. or 9,000 h.p. as alternating.

Mr. Whalley said that this was the only country that had not committed itself to the manufacture of polyphase machinery. In St. Petersburg there was one station distributing polyphase currents and running in competition with two others using single-phase. Polyphase currents were in use to a large extent abroad, and were often used not only for distribution, but in workshops using small motors. He thought they had more work than they could tackle with continuous-current manufacture, and suggested that the Institution should issue a standard table of efficiencies, as there were too many motors turned out which were not properly tested.

Mr. C. H. Wordingham said he was very much interested in the paper, and approached it from a central-station point of view, but he had hoped to hear more about distribution from sub-stations. He still stuck to his old idea—that continuous current was the thing to sell to consumers, but that for transmission over long distances multiphase generation was essential. Mr. Earle had made no reference to rotary transformers. Four hundred-volt lamps would solve many difficulties, but they must not forget that they had that very important body the Board of Trade to deal with, and he was pretty certain that they would not allow the use of 400-volt lamps with 800 volts across the outers of a three wire installation.

Mr. Earle said he referred to the use of 400-volt lamps on two-wire installations.

Mr. Wordingham, continuing, said that the question of trouble with commutators depended upon where the motors were bought, but he thought the difficulties were negligible. The complications of switch gear with three-phase currents was a very important question, but could be avoided by using low-pressure currents.

Mr. Ritchie said they must consider the small consumer, and it was advantageous to him to have a motor without a commutator. For regulation of speed, direct-current motors were now favourable. As to the figures from Niagara Falls, the current was mostly used for tramways and a lot for electrolytic purposes, which must, therefore, be continuous.

The **Chairman** said that the last year's president of the Institution was very much in favour of alternating currents, and that this meeting was of quite the other opinion. There were very serious objections to alternating currents, and he had no doubt that continuous current was the proper thing. He was afraid there was an evil day in store for three-phase users, when current, which would be continuous, came to be generated direct from coal. Parallel running with alternating currents presented considerable difficulties. For arc lighting, direct currents were much more favourable. They could not do without continuous currents if they tried. They must have exciters in an alternating station, and these must have commutators. If they looked at some of the metropolitan companies' works costs, they would see that those for continuous current were much lower than those for alternating.

Mr. Earle, in reply, said that on the Continent, where he had lost an order for direct-current machinery, owing to the fact that the firm were intending to use alternating current, on going back to the same place a year after he had found the alternating machinery replaced by direct-current machinery. When starting his paper he had a view in favour of three-phase currents, but the more he went on with it the more he saw that direct currents were right, and had therefore changed his views at the end.

The meeting concluded with a vote of thanks to the author.

ELECTRIC OSCILLATIONS.

The first of a series of four Cantor lectures on "Electric Oscillations and Electric Waves" was delivered by Prof. J. A. Fleming at the Society of Arts on Monday last. There were a goodly number present, and we would recommend all electrical engineers who wish to become *au fait* with this subject to make an effort to attend the remaining lectures of the course. The experiments arranged by Prof. Fleming were most successful, and conduced to the ready understanding of the subjects dealt with. After a brief reference to the adoption of electric oscillations to wireless telegraphy, Prof. Fleming commenced his subject by explaining that his lectures would deal with oscillations of a frequency of very much higher value than were employed in alternating-current distribution; instead of a frequency of from 25 to 100 complete periods per second, frequencies of from 100,000 up to millions per second would be dealt with. With this great increase of frequency it would be shown that resistance loses much of the importance which it exercises with ordinary electric lighting currents, and that induction and capacity became much more important. Again, it would be shown that the crystallised idea of some with respect to conductors and non-conductors, and with respect to the current being the same in every part of the same circuit, would be rudely upset. The usual methods of producing the low-frequency currents were quite useless when one required to generate these electrical oscillations. There was only one method known by which this could be done, and that was by the discharge of condensers. In order to get the oscillatory discharge, well-

Digitized by Google

known rules had to be followed, first enunciated mathematically by Lord Kelvin in 1851. He showed that the discharge would be oscillatory if

$$R^2 < L\frac{L}{C};$$

where R = the resistance of the circuit;
L = the self-induction;
C = the capacity of the condenser.

The fact that the discharge could be oscillatory was first discovered by Joseph Henry in 1842, when studying the magnetising of needles by means of a discharge from a Leyden jar. The varied result of this operation led this experimenter to a belief that in certain cases the discharge must be oscillatory. Later on, Mr. Boys, by means of photography and revolving mirrors, obtained records of these oscillatory discharges, and studied the causes which varied the number of actual oscillations which occurred. One of the great essentials for producing an oscillatory discharge was the very sudden release which took place when the discharge passed through air; the breakdown of the air from a perfect insulator into a fairly good conductor was a most marvellous and hitherto unexplained phenomenon. Prof. J. J. Thomson had shown that the electric pressure between the points was not sufficient to start the discharge. A list of dielectric strengths in kilo-volts per centimetre was then given. The figures were:

Micanite	4,000
Mica	2,000
Ebonite	540
Linseed oil	83
Cotton seed oil	67
Air film 2mm. thick	57
,, 16mm. ,,	27

He and several others had tried to use oil as an insulator, but the breakdown was not so sudden as when the discharge took place through air. The formula for the frequency of the electric oscillations which was most convenient for use in ordinary work was the following:

The frequency equals $\frac{5{,}000{,}000}{\sqrt{C\,L}}$,

where C is the capacity of the condenser in microfarads, and L the induction of the circuit in centimetres. It must be remembered, however, that the induction of a circuit to an oscillatory discharge was not the same as for ordinary alternating currents. The following formula would be found accurate for ascertaining the induction of these high-frequency waves, as expressed in terms of the length and diameter of the wire used:

$$L = 2\,l\left\{2{\cdot}3026\,\log_{10}\frac{4\,l}{d} - \alpha\right\}$$

where L = the length of the wire in centimetres;
d = its diameter; and
α is a constant depending on the form of the circuit.

For a straight wire $\alpha = 1$, for a circle of a single circular conductor $\alpha = 2{\cdot}45$, and for a circle of square conductor $\alpha = 2{\cdot}6$. It was then impressed upon those present that when one spoke of a frequency of 1,000,000 of these electrical oscillations, it was not meant that there were 1,000,000 oscillations each second. What really took place was that there were a few, say 10 to 15, oscillations of that frequency, and then a pause in which no discharge took place, then another discharge, etc. The experiment was shown that a transformer could be constructed for these oscillatory currents, and that a zinc screen, even of the thinnest zinc, was quite sufficient to cut off the effect of the primary on the secondary. With the apparatus exhibited there were 12 turns in the primary, and three in the secondary, which lighted up a four-volt lamp. This was a step-down transformer. To construct a step-up transformer, Prof. Fleming showed that the ordinary method of transformer design must be avoided. It was most important to have a considerable space between the adjacent convolutions of the primary in order that the self-induction of the primary circuit should be kept low. This was clearly demonstrated by an experiment. These transformers were accordingly constructed with a few turns on the primary, wound with a considerable insulation space between the adjacent turns of the spiral, and a single layer of secondary wire was placed over the primary. It was found that a glass insulation was the best to use; it was also found that it was better to make the transformer long rather than to try more than one layer. Experiments were also shown that iron cores in a coil did not much affect this induction as far as these electrical oscillations were concerned. This was intimately connected with the fact that with these high frequencies the current was almost carried by the skin of the wire. The lecturer explained that the ordinary formula for ascertaining this effect did not apply to these high-frequency currents. A most interesting experiment was made by Prof. Fleming to show how these oscillatory currents could be set up in a poor vacuum without any exterior conductors; for this purpose a bulb similar to that used for the large Sunbeam lamp, but with a comparatively poor vacuum, was placed inside a coil of wire through which these electric oscillations were being passed. The result was a circulation of electric discharges round the rarefied air in the bulb, which produced a most brilliant illuminating effect.

ELECTRICAL CONTACTS.*

BY FRANK C. MASON.

It is curious that the subject of electrical contacts has received so little attention in the literature and discussions of the general subject of electrical application. At the basis of nearly every variety of electrical apparatus, whether for signalling with small currents or for the larger work of heating, lighting, generating, and developing electric power and the application of electricity to chemical processes, the contact or point of discontinuity in the circuit is found as an essential part of the apparatus or of the method.

It is well at this point to say that this paper will be limited to those uses of electricity employing relatively small currents, as in telephony, telegraphy, and signalling, and will not touch on the larger field that its subject embraces in the utilisation of heavy currents. However, the line of demarcation between the light current and the heavy current is now by no means so sharply drawn as it was in the days when the primary battery, in one form or another, was the sole dependence of the telephone and telegraph engineer. When we see the dynamotor and the storage battery used as the central source of energy for a telegraph, fire-alarm, and telephone system, we naturally wonder for how long we can speak of the light current applications of electricity as a distinction from those employing large and powerful currents generated by dynamos.

Contacts may be roughly grouped into three classes: those that are intended to be permanent (such as joints in wire and cables); those that are semi-permanent (such as contact between wire and binding posts) and operative contacts; or those that are intended to be opened and closed at will, as in keys, switches, etc.

To all these kinds of junctions, two enemies exist constantly tending to destroy efficient electrical contact—chemical action and dirt. It is scarcely necessary to speak of mechanical strains, which are guarded against naturally by the exercise of common sense. Chemical action, as it applies to contacts, is generally due to the remnants of some compound or chemical used in soldering, and to the action of air and moisture (either singly or in conjunction), producing oxidation of the surfaces in contact. This action is enormously enhanced by the formation of sparks at contacts of the operative kind, the resultant film of oxide being generally a non-conductor, and interfering greatly with the operation of the contact. Dirt, as Emerson says, is merely "matter out of place." In electrical work dirt means any non-conducting substance that interferes with good electrical contact. It is often dust, but in operative contacts is more frequently the products of oxidation of the points of contact themselves, where (as is too often the case) these are of the baser and more oxidisable metals.

Permanent joints, or contacts, are used both in line conductors and in instruments. Nowadays, the general introduction of hard-drawn copper wire for overhead line

work has reduced practice in this kind of jointure to a question of the best way to handle that material. Experience has shown that soldering such joints draws the temper of the wire, making a point of mechanical weakness, while the ancient habit of linemen of twisting the wire at the joint into tight spirals, leads to the same result. For these reasons the twisted and soldered joint must necessarily give way to one of the various and excellent types of tubular joint now manufactured for the purpose. In cable work especially, where paper insulation is used, the best practice now, strangely enough, is to use merely the twisted joint without solder. The wire being soft and subject to no strains, the joint is abundantly strong, while its sheathing, after jointing fully, protects it from the harmful action of the atmosphere and moisture. To solder such a joint would add the danger of corrosion from the dissolving action and slow electrolysis of the fluxes used.

Permanent joints in switchboards and instruments, being protected from the weather, are generally soldered. The wires used should be tinned, so as to leave no excuse for the use of the mischief-making chemicals sold as "soldering solutions." Tubular solder having resin or stearine flux in its hollow part should be used, and the utmost watchfulness employed to keep acid and "salts" away from the work. One easy joint made by these means may plant the seeds of trouble to be reaped later, and, by the peculiar provision of fate, almost invariably just when trouble or breakdown is most to be feared.

Semi-permanent contacts are, practically, of only two kinds, binding posts and fuses. The average American binding post is a piece of metal with a hole drilled through to receive the wire and another drilled and tapped to receive a set screw, which may or may not have a pointed end. The design of this type of binding post is utterly vicious. The screw may shear the wire nearly in two, leaving it so that the slightest strain will break it off, or it may not come down to a tight bearing on the wire, leaving a loose joint ready to collect dirt and become inoperative. Much the better type is that variety of binding post in which the wire is firmly held between two flat surfaces, thus ensuring a large area of contact, and which is provided with a lock-nut so as to avoid any danger of the binding washer working loose. In instruments having binding posts of the other type, considerable improvement can be introduced by putting small hexagonal nuts a little larger than the driving heads of the binding screws on the latter, and setting them down firmly on the top of the post to act as lock-nuts.

In fuses, which are an absolutely necessary part of any installation in a modern city traversed by electric light and railway conductors, an excellent opportunity for bad contacts presents itself. The practice of securing the fuse wire under a washer or the head of a screw is very bad, as the wire is strained, is apt to be reduced in section at some point, and cold flow of the fuse may take place. To obviate these troubles it is usual to attach pieces of copper to the ends of the fuse wire, screwing these down tightly under the binding washers. If the fuse, as is too often the case, is merely squeezed into the copper end, the trouble is only transferred to another point. Hence the best solution of the fuse difficulty is to use copper lugs, to which the fusible wire is securely soldered, held down by screws provided with lock-nuts. Care should be taken in installing fuses not to set them in place under strain, as their expansion and contraction under temperature changes produce crystallisation of the metal or reduction of its cross-section at some point.

While the two classes of contacts already referred to are, in a large measure, in the hands of the operating force of a fire-alarm, telegraph, or telephone installation, the third class, and the most important of all to us—the working contacts of instruments—are confined to these structures, and their nature is determined by the manufacturer. In keys, relays, vibrating gongs, the switching apparatus of the telephone station and in all other places where signalling circuits must be made and broken, sparks will be formed, and no practical device known to the art can prevent their formation. While dust, always inimical to good contacts, can be excluded from such places by proper construction of the instrument, nothing will prevent the formation of oxides at the point of sparking, which is also the point of contact, except making these points of some material that will not oxidise.

For this purpose, the only substances known that are at the same time good conductors of electricity and possess the necessary qualities of mechanical strength, are platinum and a few other of the rarer metals, such as iridium and gold. The consensus of opinion and experience has shown platinum or certain of its alloys to be the only substance commercially available for the construction of contact points of this character. Unfortunately, platinum is a material of such great value that the expense of such contacts is greater than that of any other kind, and, therefore, the temptation of the manufacturer to replace such contacts with those of cheaper material, or to skimp the size, has been very great, and too often has he fallen before it. He has introduced contact points of the baser metals in his instruments, and this has far too often invited, if not assured, disaster.
